1 **Abstract**

2 Synaptic transmission is mediated by neurotransmitter release at presynaptic active zones (AZs)

3 followed by postsynaptic neurotransmitter detection. Plastic changes in transmission maintain

4 functionality during perturbations and enable memory formation. Postsynaptic plasticity targets

5 neurotransmitter receptors, but presynaptic plasticity mechanisms directly regulating the

6 neurotransmitter release apparatus remain largely enigmatic. Here we describe that AZs consist

7 of nano-modular release site units and identify a molecular sequence adding more modules

8 within minutes of plasticity induction. This requires cognate transport machinery and a discrete

9 subset of AZ scaffold proteins. Structural remodeling is not required for the immediate

10 potentiation of neurotransmitter release, but rather necessary to sustain this potentiation over

11 longer timescales. Finally, mutations in Unc13 that disrupt homeostatic plasticity at the

12 neuromuscular junction also impair shot-term memory when central neurons are targeted,

13 suggesting that both forms of plasticity operate via Unc13. Together, while immediate synaptic

14 potentiation capitalizes on available material, it triggers the coincident incorporation of modular

15 release sites to consolidate stable synapse function.

Introduction

Neurotransmitter-laden synaptic vesicles (SVs) release their content at presynaptic active zones (AZs) in response to Ca^{2+} influx through voltage gated channels that respond to action-potential (AP) depolarization. Neurotransmitter binding to postsynaptic receptors subsequently leads to their activation for synaptic transmission. Modulation of transmission strength is called synaptic plasticity. Long-term forms of synaptic plasticity are major cellular substrates for learning, memory, and behavioral adaptation[1, 2]. Mechanisms of long-term synaptic plasticity modify the structure and function of the presynaptic terminal and/or the postsynaptic apparatus. AZs are covered by complex scaffolds composed of a conserved set of extended structural proteins. ELKS/Bruchpilot (BRP), RIM, and RIM-binding protein (RBP) functionally organize the coupling between Ca^{2+}-channels and release machinery by immobilizing the critical (M)Unc13 release factors in clusters close to presynaptic Ca^{2+}-channels and thus generate SV release sites, at both mammalian and *Drosophila* synapses[3-12]. Whether and how discrete AZ release sites and the associated release machinery are reorganized during plastic changes remains unknown.

One crucial form of presynaptic plasticity is the homeostatic control of neurotransmitter release. This process, referred to as presynaptic homeostatic potentiation (PHP), is observed in organisms ranging from invertebrates to humans, but is perhaps best illustrated at the larval neuromuscular junction (NMJ) of *Drosophila melanogaster*[13, 14]. Here, PHP requires the core AZ-scaffolding proteins RIM, RBP and Fife[15-17] and physiologically coincides with the upregulation of SV release sites[17, 18]. Yet it is unknown how these AZ-scaffolds mediate release site addition, which downstream molecules are needed for PHP, whether AZ-scaffold independent reactions occur and whether these mechanisms extend to other forms of plasticity, e.g. during learning in the central nervous system.

39   Here, we combine genetic and electrophysiological analysis to reveal a molecular

40   sequence that triggers structural remodeling of AZ scaffolding proteins (BRP/RBP) that

41   ultimately lead to (M)Unc13 addition within minutes. Using super-resolution light microscopy

42   we identify a modular AZ nano-architecture built by these proteins (which corresponds to SV

43   release sites) that rapidly extends by incorporating additional modules for plasticity. This "rapid

44   remodeling" critically depends on the core AZ scaffolding proteins RBP/BRP, but neither on the

45   early AZ assembly factors Liprin-α/Syd-1, nor on RIM or Fife. Additionally, AZ-remodeling

46   was abolished in transport mutants previously shown to promote BRP/RBP transport. Strikingly,

47   rapid addition of AZ nano-clusters was not required for the immediate expression of PHP on a

48   minutes' timescale, but was essential to sustain potentiation thereafter. We identify Unc13A as a

49   direct molecular target for PHP in experiments in which Unc13A was delocalized from the AZ

50   scaffolds. This mutant displayed sizable synaptic transmission but fully lacked PHP and AZ-

51   remodeling. The same interference in mushroom body Kenyon cells of the *Drosophila* brain

52   eliminated short-term memory, indicating that Unc13A is also a plasticity target in the central

53   nervous system. In summary, we show that synapses capitalize on the available AZ material for

54   immediate potentiation, but coincidently undergo release site addition via modular building

55   blocks to consolidate stable synaptic potentiation. Thus, our work lays a foundation from which

56   to mechanistically understand a likely conserved presynaptic plasticity process important for

57   dynamically adjusting and stabilizing neurotransmission across multiple timescales.

4

58 **Results**

59 **Rapid and chronic homeostatic plasticity regulate AZ protein levels**

60 As a robust paradigm for assessing presynaptic plasticity over different time scales, we focused

61 on PHP, which is well characterized at *Drosophila* NMJs[13]. To induce plasticity on a timescale

62 of minutes, postsynaptic ionotropic glutamate receptors were partially blocked using the non-

63 competitive open-channel blocker Philanthotoxin-433 (PhTx)[19] (Fig. 1a-d). This reduces

64 postsynaptic sensitivity to neurotransmitter release from single SVs (reflected in a reduction of

65 the amplitude of spontaneously occurring "minis", single SV fusion events, Fig. 1b). Initially,

66 this also leads to a proportional decrease in AP-evoked transmission, but in less than 10 minutes,

67 PHP increases the number of SVs released per AP (quantal content) to compensate for the

68 postsynaptic interference, resulting in AP-evoked transmission comparable to baseline levels

69 (Fig. 1b)[19]. To identify molecular adaptations during plasticity, we investigated whether the

70 levels of any of the evolutionarily conserved AZ proteins were altered. We thus immunostained

71 against BRP, RBP, Unc13A (we focused on Unc13A, the Unc13 isoform dominating evoked SV

72 release at *Drosophila* NMJ synapses[7]; flybase: unc-13-RA), Syx-1A, Unc18 and Syd-1 (as

73 motoneuronally expressed Syd-1-GFP) (Fig. 1c; Supplementary Fig. 1a). In agreement with

74 previous observations[18, 20], we found that 10 minutes of PhTx treatment increased AZ BRP-

75 levels by about 50% (Fig. 1c,d). In addition, we found that RBP, Unc13A and Syx-1A increased

76 by about 30%, 60%, and 65%, respectively (Fig. 1c,d). The AZ levels of RBP/BRP,

77 Unc13A/BRP and Syx-1A/BRP scaled proportionally over all AZ sizes (Supplementary Fig. 1b;

78 Ctrl, black lines). This proportionality was preserved upon PhTx treatment (Supplementary Fig.

79 1b; PhTx, blue lines). Notably, the AZ-levels and distribution of the essential Sec1/(M)Unc18

80 family protein Unc18 – which was recently found to function in PHP[21] – were unaffected (Fig.

5

81   1c,d;), demonstrating specific up-regulation of a subset of AZ proteins. Another AZ protein, the

82   assembly factor Syd-1 even displayed a slight reduction upon PhTx (Supplementary Fig. 1a),

83   further underscoring a high degree of specificity.

84   To verify that these AZ-adaptations were specific to functional glutamate receptor

85   interference, and to address their relevance over a longer time window, we investigated larvae

86   bearing mutations in a glutamate receptor subunit (Fig. 1e-h). Deletion of the high-conductance

87   receptor subunit IIA (GluRIIA) results in a similarly reduced postsynaptic sensitivity to single

88   SV fusion events (Fig. 1f) as PhTx treatment (Fig. 1b). Because under these circumstances PHP

89   also increases quantal content to achieve similar AP-evoked transmission (Fig. 1f), *gluRIIA*

90   mutants have extensively been used to investigate long-term PHP (over the 3-4 days of larval

91   development)[22, 23]. Immunostainings against BRP, RBP, Unc13A, and Syx-1A confirmed their

92   (in this case larger) elevation on this longer timescale (compare Fig. 1g,h with 1c,d) (100%,

93   70%, 400% and 200%, respectively, compared to 50%, 30%, 60% and 65% upon PhTx

94   treatment). Unlike the stoichiometric increase observed for BRP/Unc13A within minutes, this

95   long-term PHP revealed enhanced Unc13A AZ-incorporation (Supplementary Fig. 1c). Another

96   distinction was a remarkable reorganization and 8-fold increase of Unc18 (Fig. 1g,h;

97   Supplementary Fig. 1d,e). Our data thus imply that considerable AZ restructuring occurs within

98   minutes of PHP induction, which is further enhanced across longer-lasting timescales.

99

100   **Rapid addition of Unc13A/BRP/RBP release site modules during homeostatic plasticity**

101   We next sought to investigate how the altered levels of AZ proteins during PHP affected their

102   nanoscopic topology by super-resolution STED microscopy (x-y resolution ~ 30-40 nm). As

103   noted before, planar AZs revealed clearly distinguishable individual Unc13A/BRP/RBP spots

6

104   arranged in a ring-like geometry[3, 7-9] (Fig. 2a). It was recently shown by single molecule

105   imaging, these individual clusters likely contain several (probably few tens of) molecules in the

106   case of BRP [24]. We detected the number of clusters per AZ in single AZ-images with a simple

107   peak detection algorithm which was largely heterogeneous for all three proteins (Fig. 2c-e (black

108   bars)). However, in all cases the cluster number per AZ increased upon PhTx-treatment (Fig. 2c-

109   e (blue bars)), and slightly increased further in *gluRIIA*[Null] mutants (Supplementary Fig. 2a;

110   brown bars). With increasing AZ-cluster number the AZ diameter (measured from the AZ center

111   to the center of the clusters) also increased in both conditions (Supplementary Fig. 2b,c),

112   consistent with previous STED analysis performed on BRP-rings [18]. Notably, the observed

113   remodeling only affected cluster numbers, and did not alter their intensities (Supplementary Fig.

114   2b,c). Thus, the first conclusion of our analysis is that PHP increases the number

115   Unc13A/BRP/RBP nano-clusters per AZ within minutes.

116   We also wanted to investigate whether the overall AZ-topology changed upon cluster

117   incorporation. Notably, averaging of STED-images was recently used to generate a three-

118   dimensional model of an "average" synapse, displaying the mean protein localization at high

119   resolution [25]. Thus, to compare the overall single AZ-topology, AZ images were centered, sorted

120   by the number of clusters, aligned by rotation, and averaged. Two different alignment methods

121   were used. In the first procedure, images were simply rotated such that the cluster with the

122   highest intensity was positioned to the top (Supplementary Fig. 3a and Methods for details).

123   Even though this procedure only targeted a single pixel per image (the position of the brightest

124   cluster), the remaining (lower intensity) clusters were often found in similar relative positions,

125   such that averaging revealed a simple polygonal geometrical series (Supplementary Fig. 3a),

126   demonstrating some regularity. In a more refined analysis, we simultaneously considered the

7

127   position of all clusters per AZ (Supplementary Fig. 3c and Methods for details) which also

128   revealed a simple geometrical pattern for Unc13A, BRP and RBP (Fig. 2f-h and Supplementary

129   Fig. 3c). This stereotypical arrangement was best seen for AZs containing 2-6 clusters but less

130   clear for AZs containing more than that (which could mean that these are less regular;

131   Supplementary Fig. 2d,e). This arrangement was unaltered upon PhTx-treatment or *gluRIIA*

132   ablation (Figure 2f-h and Supplementary Fig. 4a-c). Notably, the results of these averaging

133   approaches obviously produced specific patterns, as neither random categorization of the single

134   AZ images nor applying this methodology to Syx-1A and Unc18 (which are diffusely distributed

135   at the AZ) resulted in regular but instead in highly irregular/random fluorescence patterns

136   (Supplementary Figs. 3b and 2f,g). This also demonstrates that structural features are only

137   conserved across AZs containing the same number of clusters. It should be noted that only the

138   average images (Fig. 2f-h; Supplementary Fig. 4) depend on this procedure, while detecting the

139   effects of PhTx or *gluRIIA* ablation on cluster numbers (Fig. 2c-h) was fully independent of this.

140   Thus, these findings imply that complexes of the core AZ-scaffold form discrete nano-

141   modular structures, which correspond to SV release sites, and that rapid presynaptic plasticity

142   triggers their fast AZ-incorporation which is even further enhanced over longer-timescales.

143

Mutations that impair BRP/RBP transport disrupt rapid AZ-remodeling

145   The remarkable remodeling of AZ material within the short timeframe of PhTx-treatment

146   (minutes) raised the question of how this is mechanistically achieved. We first considered

147   whether local presynaptic protein translation could be required [26]. However, treatment of larvae

148   with 50 µg/ml of the translation blocker cycloheximide (prior and during PhTx-treatment) did

149   not disrupt structural remodeling of BRP or vGlut (vesicular glutamate transporter) at AZs

150 (Supplementary Fig. 5a), consistent with re-modeling being translation-independent. Moreover,

151 the functional increase in quantal content remained expressed in the presence of the blocker

152 (Supplementary Fig. 5b), consistent with previous reports[19, 20].

153   Because active kinesin-dependent protein transport is required for long-term homeostatic

154 plasticity in *gluRIIA*[Null] mutants[27], we asked whether BRP/RBP transport mechanisms might be

155 employed for AZ remodeling. For this we investigated proteins involved in BRP/RBP transport

156 by their mutation which causes abnormal BRP/RBP accumulation in the moto-neuronal axons,

157 such as Atg1 (Unc-51)[28], serine–arginine (SR) protein kinase at location 79D (Srpk79D;[29, 30]),

158 and App-like interacting protein (Aplip-1, Jip1 or JNK interacting protein in mammals), a

159 selective RBP transport-adaptor[31] (Fig. 3a,b). While we observed clear PhTx-induced BRP-

160 /Unc13A-upscaling in Wild-type controls as well as in *atg1* mutants (Fig. 3a,b), remodeling was

161 fully absent upon null-mutation of *srpk79D*, *aplip-1*[32] or in animals bearing an Aplip-1 point

162 mutation that selectively prevents kinesin light chain interaction (*aplip-1*[ek4])[33] (Fig. 3a,b).

163 Additionally, STED microscopy revealed that *aplip-1*[ek4] and *srpk79D*[ATC] mutants appeared to

164 contain fewer BRP/Unc13A clusters per AZ on average than Wild-type (compare Fig. 2c,d with

165 Fig. 3c) and fully lost the capacity to increase cluster numbers upon PhTx-treatment (even a

166 decrease was observed, Fig. 3c). We also discovered that upon motoneuronal Aplip-1 or

167 Srpk79D knock-down, Unc13A-GFP co-accumulated with aberrant axonal BRP aggregates

168 (Supplementary Fig. 5c,d). Interestingly, a partial co-accumulation of BRP/Unc13A-GFP (but to

169 a lower extent in comparison to the knock-downs) was also present in the control situation, in

170 line with an at least partial co-transport that we occasionally observed in live-imaging

171 experiments (Supplementary Fig. 5c-g; Movie 1).

172   We further wanted to elaborate on the involvement of active protein transport during

173   PhTx-induced AZ-remodeling by interfering with the cytoskeletal "tracks" used for short-range

174   transport with Latrunculin B (an actin polymerization blocker). While the AZ levels of

175   BRP/Unc13A were already slightly enhanced by Latrunculin B treatment (Supplementary Fig.

176   6a,b), PhTx-treatment failed to induce the typical increase of the AZ levels of these proteins (in

177   fact a reduction was observed, Supplementary Fig. 6a,b). Thus, the actin cytoskeleton and active

178   BRP/RBP transport are required for rapid AZ remodeling.

179

180   **Rapid homeostatic remodeling of AZ structure depends on BRP and RBP**

181   We next investigated which of the evolutionarily conserved core AZ scaffolding proteins are

182   required for rapid AZ-remodeling. Loss of RBP fully blocked the rapid, PhTx-induced increase

183   of BRP/Unc13A (Fig. 4a,b). Also BRP was essential, because the typical increase in Syx-1A and

184   Unc13A observed upon PhTx treatment was abolished (Compare Fig. 4a,b with Fig. 1c,d).

185   Notably, BRP-amounts appear to be rate-limiting because PhTx-induced AZ-remodeling was

186   blocked in larvae heterozygous for a *brp* null allele (brp$^{\text{Null}}$/+)(Fig. 4a,b). In contrast, null

187   mutation of RIM, which abolished PHP[17], did not interfere with AZ-remodeling (Fig. 4a,b).

188   Furthermore, the simultaneous deletion of RIM and Fife (a possible RIM homologue which is

189   required for PHP[15, 34]) did not interfere with AZ-remodeling. Thus, RIM and Fife appear to act

190   downstream of BRP/RBP and are non-essential for AZ-remodeling (Fig. 4a,b).

191   AZ assembly is initiated by the conserved scaffolding proteins Liprin-α and Syd-1, which

192   both regulate AZ size[35-41]. We reasoned that AZ growth –as observed here during plasticity– may

193   capitalize on the same molecular machinery as *de novo* AZ formation, and therefore tested

194   whether BRP/Unc13A-scaling depended on those proteins. However, *liprin-α*$^{\text{Null}}$ and *syd-1*$^{\text{Null}}$

10

195   mutants revealed normal PhTx-induced BRP/Unc13A-scaling (Fig. 4a,b), indicating that these

196   factors are dispensable. Thus, systematic investigation of evolutionarily conserved AZ

197   scaffolding proteins reveals a selective dependence on the core AZ-scaffolds BRP and RBP for

198   structural remodeling during plasticity.

199

200   **AZ-remodeling is required for the chronic, but not rapid, functional expression of**

201   **homeostatic plasticity**

202   Several studies have shown that presynaptic release positively correlates with AZ-size[3, 42-45].

203   Therefore, we expected that the increase of AZ-BRP/Unc13A observed upon PhTx treatment

204   would functionally increase presynaptic release (Fig. 1a-d). However, it is not entirely obvious

205   whether the AZ-remodeling (which continues beyond the minutes' timescale during long-term

206   PHP (Fig. 1e,g,h) would be essential for rapid PHP. For instance, loss of RBP was shown to

207   occlude both AZ remodeling (Fig. 4) and the functional increase in quantal content [16], suggesting

208   a pivotal role in both adaptations. Yet PHP and AZ-remodeling do not go hand-in-hand in the

209   case of RIM (and Fife) mutants, whose AZs remodel, but which cannot express PHP (increased

210   quantal content[15, 17]). These observations prompted us to systematically investigate the relevance

211   of AZ-remodeling for the rapid induction and sustained expression of PHP.

212   We first investigated the dependence of rapid PHP on the rapid remodeling of

213   Unc13A/Syx-1A in brp^{Null} larvae. Strikingly, AZ-remodeling was blocked (Fig. 4a,b), but

214   functional PHP expression (an increased quantal content) persisted at levels comparable to the

215   Wild-type/Control situation (Fig. 5a,b). In addition, mutants of Srpk79D (whose AZs also do not

216   undergo PhTx-induced AZ-remodeling; Fig. 3a,b and replotted in Fig. 5d) were likewise able to

217   increase their quantal content (Fig. 5c), showing that AZ remodeling can be uncoupled from

218 rapid PHP expression. Thus, even though AZ-remodeling occurs on a similar time-scale, it is not

219 required to rapidly enhance the quantal content in these cases.

220 We next investigated whether elevation of the AZ protein levels was required to

221 consolidate the increased quantal content over chronic time-scales in *gluRIIA*^{Null} mutants (Fig.

222 5e-h). Indeed, PHP was severely impaired in *brp*^{Null},*gluRIIA*^{Null} double mutants (Fig. 5f). In an

223 otherwise Wild-type background, the increase in quantal content (upon *gluRIIA*-null mutation)

224 was much larger than when BRP was additionally deleted (Fig. 5f). We could ensure that the

225 impairment was not due to the overall reduced release in *brp*^{Null} mutants, as a loss to compensate

226 for the *gluRIIA* ablation was also seen in *srpk79D*^{ATC} mutants (which had comparable synaptic

227 transmission to Wild-type cells (Fig. 5g), no AZ-remodeling upon PhTx-treatment (Fig 3a,b),

228 intact PHP upon PhTx-treatment (Fig. 5c) and severely impaired PHP expression in *gluRIIA*^{Null}

229 (Fig. 5g)). Importantly, AZ-remodeling was also fully blocked in *gluRIIA*^{Null};*srpk79D*^{ATC} double

230 mutants (Fig. 5h). An intermediate behavior was seen in the case of the *aplip-1*^{ek4} mutant,

231 (Supplementary Fig. 7), possibly because other transport adapters might compensate in this

232 situation. Together, this suggests that PHP rapidly increases neurotransmitter release through

233 modulation of the available AZ components, but in addition immediately induces AZ-remodeling

234 to ensure its consolidation.

235

236 **Presynaptic potentiation requires Unc13A**

237 We next sought to identify the molecular substrate of PHP. Previous experiments established a

238 requirement of the α1 voltage gated Ca^{2+}-channel subunit Cacophony (Cac)[19, 46]. In line with

239 this, the levels of Cac as well as the Ca^{2+}-influx increase upon PhTx treatment (Fig. 6a,b)[46-48].

240 We furthermore investigated Unc13A. A slight PhTx-induced BRP-/RBP-scaling persisted upon

241 Unc13A loss, but was weaker than in the Wild-type situation (Fig. 6a,b), possibly due to slightly

242 elevated BRP/RBP-AZ-levels already in the non-PhTx-treated *unc13A*[Null] situation[7]. Notably,

243 Cac-levels were still increased, even to a slightly larger extent than in the Wild-type situation

244 (Fig. 6a,b). However, functional PHP, the increase in quantal content, was completely lost

245 (Fig. 6c,d). This indicates that Unc13A –like RIM and RBP[16, 17]– plays an essential role in the

246 plastic enhancement of NT release during PHP.

247

248 **The Unc13A N-terminus is critical for rapid PHP, AZ-remodeling, and learning**

249 The observation that Unc13A is essential for PHP is fully consistent with the previous findings

250 that RIM and RBP are required ([16, 17], because these proteins likely function in Unc13A AZ

251 recruitment and activation (see discussion). As in other species (*M. musculus*/*C. elegans*), this

252 interaction depends on the (M)Unc13 N-terminus[7, 49-53]. To investigate the functional relevance

253 of the Unc13A N-terminus for rapid PHP and AZ-remodeling, we used an Unc13A mutant

254 lacking the N-terminal AZ-localization sequence (named C-term-GFP; Fig. 6e), which uncouples

255 Unc13A from the central BRP/RBP scaffold[3] (and therefore supposedly also uncouples SV

256 fusion from a possible regulatory function of RIM –see discussion). Importantly, the magnitude

257 of AP-evoked synaptic transmission in these mutants was largely restored compared to the

258 detrimental effect of *unc13*[Null] mutation (compare Fig. 6h (C-term-GFP; grey traces) with Fig. 6h

259 (full-length Unc13A-GFP; black traces) and [3]). However, in contrast to control larvae (*Unc13*[Null]

260 with full-length Unc13A-GFP rescue; Fig. 6f-i), C-term-GFP mutants (*Unc13*[Null] with C-term-

261 GFP rescue; Fig. 6f-i) completely lacked AZ-remodeling (Fig. 6f,g) (note that BRP levels were

262 already enhanced in the non-PhTx-treated group, Supplementary Fig. 8a,b), Furthermore, unlike

263 in control larvae, no rescue of evoked transmission and no increase in quantal content was seen

13

264   upon PhTx treatment, indicating that C-term mutants were deficient of functional PHP (Fig. 6h-

265   i). This demonstrates a dependence of PHP on the Unc13A N-terminus.

266   Although synapses vary tremendously in their excitability, input/output relationship, and

267   transmitter type, the presynaptic release machinery is remarkably conserved in most systems and

268   across species[54]. Thus, we wondered whether the principles of rapid presynaptic adaptation of

269   the peripheral nervous system might be utilized in other synapse types and in other forms of

270   plasticity, like the ones involved in learning and memory formation. Because short-term memory

271   functions on timescales comparable to the PhTx-induced rapid homeostatic plasticity[55], we

272   investigated whether the Unc13 C-term mutant also exhibited learning deficits.

273   We specifically expressed C-term-GFP alone, or while simultaneously knocking down

274   endogenous full-length Unc13A (Unc13A-RNAi), in mushroom body Kenyon cells (KCs). KC

275   output synapses undergo learning-induced plasticity and are required for the formation of short-

276   term memories[56]. Knockdown of endogenous Unc13A and expression of C-term-GFP were

277   confirmed using antibodies against GFP (labelling C-term-GFP but not endogenous protein) and

278   the Unc13A N-terminus (labelling the endogenous protein but not C-term-GFP where the N-

279   terminal epitope is deleted) (Fig. 7a). Additionally, we confirmed the strong efficacy of the

280   Unc13A-RNAi via Western blot (knock-down in the entire brain using the pan-neuronal elav-

281   Gal4 driver; Supplementary Fig. 9a).

282   Because the C-term-GFP construct largely rescued the detrimental effect of *unc13* null

283   mutation at the NMJ[3], we predicted that general transmission from KCs should be functional for

284   both the C-term-GFP and the C-term-GFP/Unc13A-RNAi conditions. To verify this, we

285   performed *in vivo* two photon Ca^{2+}-imaging (GCaMP6f) experiments in adult flies to assess

286   odor-evoked responses at the M4/6 (MBON-β'2mp/MBON-γ5β'2a/MBON-β2β'2a) mushroom

14

287 body output neurons, a postsynaptic circuit element directly downstream of KCs[57, 58]. Indeed,

288 robust Ca^{2+} transients in response to odor stimulation were observed in all genetic constellations

289 tested (Fig. 7b). We thus conclude that KC output synapses expressing C-term-GFP or C-term-

290 GFP/Unc13A-RNAi are functional under naive conditions. Together with the finding that naive

291 odor avoidance was not statistically different between all these groups (Supplementary Fig. 9b),

292 this allowed us to test whether either condition would interfere with learning and memory.

293   We assessed short-term memory in adult *Drosophila* using classical aversive olfactory

294 conditioning. Flies were trained by pairing an odor with an electric shock and learning was

295 scored by subsequently assaying avoidance of that odor[59]. All control groups showed similarly

296 robust memory performance, while the relevant C-term-GFP/Unc13A-RNAi mutant (where

297 endogenous Unc13A is knocked down and replaced by the C-term mutant incapable of PHP

298 (Fig. 6e-i)) showed severe short-term memory impairments (Fig. 7c). Whether these impairments

299 are indeed a consequence of the loss of a similar plasticity mechanism as the one observed at the

300 NMJ or whether they are also related to differences in the synaptic transmission profile (e.g.

301 short-term plasticity which is also affected in this mutant[3]) remains to be established.

302 Nevertheless, our data clearly indicate that Unc13A is a target for similar forms of plasticity

303 (Unc13A-RNAi knockdown also impaired short-term memory, Supplementary Fig. 9b,c). Thus,

304 our data imply that structural, functional, and behavioral adaptations are linked, that different

305 forms of presynaptic plasticity may converge on Unc13A, and that multiple forms may operate

306 via conserved mechanisms.

307

Discussion

308

309 Synapses are able to modify their transmission strength by undergoing plastic changes. This

310 synaptic plasticity is crucial for neuronal circuit adaptation including learning and memory

311 processes[60, 61]. Molecular mechanisms for postsynaptic plasticity have been defined in

312 considerable detail[2]. However, presynaptic mechanisms also modulate transmission strength in

313 many synapse types and species[13, 55, 62]. Homeostatic plasticity is a well-studied form of

314 presynaptic plasticity at the *Drosophila* NMJ where an enhancement of AP-evoked

315 neurotransmitter release counterbalances decreased postsynaptic receptor sensitivity. A number

316 of relevant signaling molecules and pathways, including BMP signaling, CaMKII signaling,

317 TOR signaling, proteasomal degradation and trans-synaptic signaling are required for this[13, 14, 63-

318 65]. These factors appear to converge on two principal avenues to enhance presynaptic transmitter

319 release, via increased Ca^{2+} channel amounts and AP-induced Ca^{2+} influx[46-48] and secondly via an

320 increase in the number of releasable SVs and their associated release sites[17, 18, 48]. However, some

321 conditions were observed where Ca^{2+} influx or Ca^{2+}-channel levels were increased but the

322 quantal content was not (Fig. 6a-d and [17]), suggesting that release site addition or activation is a

323 required contributor. On the minutes' time-scale, structural AZ-remodeling was observed, yet

324 whether and how this contributes to the enhancement of NT-release remained unclear[18].

325 In the present study, we uncover a presynaptic sequence of molecular events that mediate

326 AZ-remodeling (Fig. 8). We identify the presynaptic cytomatrix as a highly dynamic structure

327 that can add discrete nano-modules of core proteins within minutes. In the initial phase of this

328 structural remodeling, RBP and BRP are needed as their loss occludes an increase in Syx-1A-

329 and Unc13A levels (Fig. 4). Somewhat unexpectedly, although AZ-remodeling occurs on the

330 same minutes' time-scale, it is dispensable for the rapid potentiation of NT-release during PhTx-

16

331　induced PHP (e.g. *brp*[Null], *aplip-1*[ek4] or *srpk79D*[ATC])(Fig. 6). However, the remodeling is

332　essential for the long-term consolidation of the potentiation (the capacity to restore the AP-

333　evoked response in *gluRIIA*[Null] mutants was severely impaired when combined with *brp*[Null] or

334　*srpk79D*[ATC])(Fig. 6).

335　　　　Thus, the rapid release enhancement appears to capitalize on AZ-material already present,

336　for example by increasing Ca^{2+} influx[46] and by the activation of already present but dormant

337　release sites consistent with PHP depending on RIM, RBP and Unc13A ({Muller, 2015

338　#15;Muller, 2012 #16}; this study). Interestingly, the rapid potentiation coincides with the

339　accumulation of BRP, Cac, RBP, Unc13A, Syx-1A and (later) Unc18 in the AZ, which is

340　required to consolidate and possibly extend the release enhancement. Thus, the synapse utilizes

341　two coincident programs which together ensure immediate rescue and also supply the synapse

342　with backup-material in the form of BRP/RBP/Unc13A nano-modules in case the disturbance

343　persists.

344　　　　Notably, recent work using STED microscopy to characterize hippocampal synapses also

345　identified AZ nano-modules by clusters of Bassoon, vGlut and Synaptophysin, and observed a

346　scaling of vGlut and Synaptophysin upon chemically induced LTP[66]. This nicely aligns with the

347　structural AZ-remodeling described here, suggesting an evolutionarily conserved process, tuning

348　synaptic transmission by adding nano-modular structures to both sides of the synapse.

349　Additionally, activity dependent alterations in Syx-1A nano-clusters were also recently

350　described[67], further pointing to the AZ being a highly dynamic structure which adapts to

351　different environmental demands.

352　　　　How does the AZ scaffold remodel within minutes? While local protein translation is

353　required for some forms of plasticity[68], acute translation block did not interfere with PhTx

17

354   induced AZ-remodeling (Supplementary Fig. 5a). However, we found evidence that effective AZ

355   protein transport and a functional cytoskeleton is a precondition here: The BRP/RBP transport

356   adaptor/regulator proteins Aplip-1 and Srpk79D were required for rapid enhancement of

357   BRP/RBP AZ levels (and loss of Aplip-1-mediated BRP/RBP transport impaired short-term

358   memory (Supplementary Fig. 9c)). Moreover, acute actin-depolymerization prevented the PhTx-

359   induced BRP/Unc13A addition into AZs, further supporting a crucial role for their transport and

360   in line with a recent study where *Drosophila* Mical, a highly conserved, multi-domain

361   cytoplasmic protein that mediates actin depolymerization, was shown to be necessary for PHP[63].

362   Considering the short timeframe of this adaptation, long-range transport appears unlikely.

363   Instead, we favor the idea that Aplip-1 and Srpk79D function to engage an AZ-proximal reserve

364   pool of components for rapid integration. This pool could originate from a local reservoir in the

365   distal axon or terminal, or even between AZs, from which plasticity may trigger integration into

366   established AZs[18]. Transport processes may fill or empty the reservoir. Between AZs, the

367   reservoir could be composed of diffusely distributed proteins falling below the detection limit[69],

368   or could reflect a local rearrangement of material (note the reduction of AZs containing few AZ-

369   protein modules after PhTx treatment (Fig. 2c-e) or upon *gluRIIA* ablation (Supplementary Fig.

370   2a)). Reducing the amount of BRP (by removing one gene copy) blocked the rapid structural

371   adaptation (Fig. 4a,b), possibly because all available material was required to build AZs of

372   proper functionality leaving no material for the reservoir. Regardless of the specific molecular

373   mechanism, guided active transport along the cellular cytoskeleton or rearrangements of the

374   cytoskeleton itself appear to serve a general function in synaptic plasticity in multiple species[63,

375   70-72].

18

376   RIM and RBP are established targets for multiple forms of presynaptic plasticity in

377   several synapse types and species[5, 16, 17, 62, 73]. Here we additionally identified a critical role for

378   Unc13A (Fig. 6). In fact, with our data we can infer the inter-relation between these factors in

379   presynaptic plasticity. RIM proteins are known to activate (M)Unc13s in several species[49, 50, 53,

380   74-76]. While *C. elegans* and mouse (M)Unc13 proteins interact via an N-terminal C2A domain

381   with RIM, no such domain is known for *Drosophila*, but the principal functional interaction may

382   well be conserved (via another region of the N-term). This was directly tested by an Unc13A

383   mutant, whose N-term was deleted[3]. This mutant largely rescued the severe loss of synaptic

384   transmission in the *unc13*[Null] condition with comparable AP-evoked transmission as the full-

385   length Unc13A rescue (Compare Fig. 6h black with grey traces). However, this mutant

386   completely lacked the capacity to undergo PHP, consistent with a required RIM/RBP/Unc13A

387   interplay for plasticity. Furthermore, expressing the same mutant in the *Drosophila* mushroom

388   body memory center severely impaired short-term memory formation (Fig. 7), pointing to a

389   relevance of the RIM/RBP/Unc13 plasticity module in the *Drosophila* central nervous system.

390   Thus, the morphological and molecular similarities between long-term sensitization in

391   *Aplysia*, presynaptic LTP in the mammalian brain and homeostatic plasticity or learning in

392   *Drosophila* indicate that the sequence of molecular events we describe here might be highly

393   conserved.

Online Methods

Experimental Model and Subject Details

Fly husbandry, stocks and handling

Fly strains were reared under standard laboratory conditions[77] and raised at 25°C on semi-defined medium (Bloomington recipe). For RNAi experiments flies and larvae were kept at 29°C. For experiments both male and female 3rd instar larvae or flies were used. The following genotypes were used: Wild type: +/+ (w^{1118}). gluRIIA^{Null}: $df(2L)cl^{h4}/df(2L)gluRIIA\&IIB^{SP22}$ (A22);*GluRIIB-GFP/+* or *AD9/df(2L)cl^{h4}* or *gluRIIA^{SP16}/ gluRIIA^{SP16}*. Supplementary Fig. 1a: Ok6::Syd-1-GFP: *Ok6-Gal4/+;UAS-Syd-1-GFP/+*. Transport mutants: Fig. 3,5; Supplementary Fig. 7: *aplip-1*^{Null}: *aplip-1*^{ex213}/Df(3L)BSC799; *aplip-1*^{ek4}: *aplip-1*^{ek4}/Df(3L)BSC799; *atg-1*: *atg1*^{ey07351}/Df(3L)BSC10; *srpk79D*^{ATC}: *srpk79D*^{atc}/srpk79D^{atc}. Supplementary Fig. 5c: Ctrl: *Ok6-Gal4/+;UAS-Unc13A-GFP/+*; *aplip-1-RNAi*: *Ok6-Gal4/+;UAS-Unc13A-GFP/UAS-Aplip-1-RNAi;* Supplementary Fig. 5d; Ctrl: *Ok6-Gal4/+;UAS-Unc13A-GFP/+*; srpk79D-RNAi: *Ok6-Gal4/+;UAS-Unc13A-GFP/UAS-srpk79D-RNAi.* Intravital imaging: Movie 1 and Supplementary Fig. 5e-g: Ok6/+;UAS-Unc13A-GFP/UAS-BRP-D3-Straw. 440

Method Details

Immunostaining

Larvae were dissected and stained as described previously[41]. The following primary antibodies were used: guinea-pig Unc13A (1:500;[7]); mouse Syx1A 8C3 (1:40; Developmental Studies Hybridoma Bank, University of Iowa, Iowa City, IA, USA; AB Registry ID: AB_528484); mouse Unc18/Rop 4F8 (1:500; Developmental Studies Hybridoma Bank, University of Iowa, Iowa City, IA, USA; AB Registry ID: AB_1157869; mouse GFP 3E6 (1:500, Thermo Fisher Scientific Inc., MA, USA, A-11120; AB Registry ID: AB_221568), mouse Nc82 = anti-BRP$^{\text{C-term}}$ (1:100, Developmental Studies Hybridoma Bank, University of Iowa, Iowa City, IA, USA; AB Registry ID: AB_2314865); rabbit BRP$^{\text{Last200}}$ (1:1000;[84]); rabbit RBP$^{\text{C-term}}$ (1:500;[9]); guinea-pig vGlut; (1:2000;[85]). Except for staining against RBP; Syx1A and Unc18, where larvae were fixed for 10 min with 4 % paraformaldehyde (PFA) in 0.1 mM phosphate buffered saline (PBS), all fixations were performed for 5 min with ice-cold methanol. The glutamate receptor blocker PhTx-433 (Sigmal-Aldrich, MO, USA) was prepared as a 4 mM stock solution either in DMSO (final DMSO concentration, 0.5%) or dH$_2$O. Rapid pharmacological homeostatic challenge was assessed by incubating semi-intact preparations in 20 µM PhTx diluted in HL3 (see below) containing 0 or 1.5 mM CaCl$_2$ for 10 min at room temperature[19]. Controls were treated in the same way but were incubated either in pure HL3 or HL3 containing 0.5% DMSO (in dependence of how PhTx stock solution was prepared) for 10 min. After incubation, the dissection was completed and the preparation was rinsed three times with fixative solution. During the dissection, extreme care was taken to avoid excessive stretching of body wall muscles, as this may significantly impair induction of homeostasis[19].

22

463 For translation block experiments semi-intact preparations were pre-incubated in HL3 containing

464 50μg/ml Cycloheximide (Chx; Sigmal-Aldrich, MO, USA) dissolved in DMSO for 10 minutes, a

465 concentration previously shown to block protein synthesis in Drosophila [86]. Rapid

466 pharmacological homeostatic challenge was then assessed by incubating semi-intact preparations

467 in 20 μM PhTx (or a similar volume of H_2O in control experiments) diluted in HL3 (see below)

468 containing 50μg/ml Chx for 10 min at room temperature. For actin-depolymerization

469 experiments semi-intact preparations were pre-incubated in HL3 containing 15 μM Latrunculin

470 B (Abcam, UK) in DMSO for 10 minutes. For control experiments larvae were incubated with a

471 solution containing a similar volume of DMSO. Rapid pharmacological homeostatic challenge

472 was then assessed by incubating semi-intact preparations in 20 μM PhTx (or a similar volume of

473 H_2O in control experiments) diluted in HL3 (see below) containing 15 μM Latrunculin B in

474 DMSO (or DMSO alone in control experiments) for 10 min at room temperature. Afterwards,

475 prepping and staining procedures were performed as described above/below. Control animals

476 were always reared in parallel and treated identically in all experiments.

477 Secondary antibodies for standard immunostainings were used in the following

478 concentrations: goat anti-HRP-Cy5 (1:250, Jackson ImmunoResearch, PA, USA); goat anti-

479 HRP-647 (1:500, Jackson ImmunoResearch 123-605-021, PA, USA); goat anti-rabbit-Cy3

480 (1:500, Jackson ImmunoResearch 111-165-144, PA, USA); goat anti-mouse-Cy3 (1:500,

481 Jackson ImmunoResearch 115-165-146); goat anti-mouse or anti guinea pig Alexa-Fluor-488

482 (1:500, Life Technologies A11001/A11073, CA, USA). Larvae were mounted in vectashield

483 (Vector labs, CA, USA). Secondary antibodies for STED were used in the following

484 concentrations: goat anti-mouse or rabbit Alexa594 (1:500, Thermo Fisher Scientific Inc.

485 A11032/A11037, MA, USA); goat anti-mouse Atto590 (1:100); goat anti-rabbit Atto590 (1:100);

486 goat anti-guinea pig star635 (1:100); goat anti-rabbit star635 (1:100); goat anti-mouse or rabbit

487 Atto647N (1:250; Active Motif; 15038/15048). Atto590 (ATTO-TEC AD 590-31) and star635

488 (Abberior 1-0101002-1) coupled to respective IgGs (Dianova). For STED imaging larvae were

489 mounted in Mowiol (Max-Planck Institute for Biophysical Chemistry, Group of Stefan Hell) or

490 ProLong Gold (Life-Technologies, CA, USA) on high-precision glass coverslips.

491 Western blot analysis was done as previously described[87]. Briefly, adult flies were dissected

492 in cold Ringer's solution and homogenized in Lysis buffer (1x PBS, 0.5%Triton, 2%SDS, 1x

493 Protease inhibitor, 1x Sample buffer) followed by full-speed centrifugation at 18℃. One brain's

494 supernatant for each group was subjected to SDS-PAGE and immunoblotted according to

495 standard procedures. The following antibodies were used: guinea-pig Unc13A (1:2000;[7]) and

496 mouse Tubulin (1:100000; Sigmal-Aldrich, MO, USA; Cat# T9026, AB Registry ID:

497 AB_477593). Antibodies obtained from the Developmental Studies Hybridoma Bank were

498 created by the NICHD of the NIH and maintained at The University of Iowa, Department of

499 Biology, Iowa City, IA 52242.

500

501 **Image Acquisition, Processing, and Analysis**

502 Confocal microscopy was performed with a Leica SP8 microscope (Leica Microsystems,

503 Germany). Images of fixed and live samples were acquired at room temperature. Confocal

504 imaging of NMJs was done using a z-step of 0.25 μm. The following objective was used: 63×1.4

505 NA oil immersion for NMJ confocal imaging. All confocal images were acquired using the LAS

506 X software (Leica Microsystems, Germany). Images from fixed samples were taken from muscle

507 4 of 3rd instar larval 1b NMJs (segments A2-A5) or nerve bundles (segments A1–A3). Images for

508 figures were processed with ImageJ software to enhance brightness using the brightness/contrast

509   function. If necessary, images were smoothened (0.5 pixel Sigma radius) using the Gaussian blur

510   function. Confocal stacks were processed with ImageJ software (http://rsbweb.nih.gov/ij/).

511   Quantifications of AZs (scored via BRP) were performed following an adjusted manual [88],

512   briefly as follows. The signal of a HRP-Cy5 antibody was used as template for a mask,

513   restricting the quantified area to the shape of the NMJ. The original confocal stacks were

514   converted to maximal projections, and after background subtraction, a mask of the synaptic area

515   was created by applying a certain threshold to remove the irrelevant lower intensity pixels. The

516   segmentation of single spots was done semi-automatically via the command "Find Maxima"

517   embedded in the ImageJ software and by hand with the pencil tool and a line thickness of 1

518   pixel. To remove high frequency noise a Gaussian blur filter (0.5 pixel Sigma radius) was

519   applied. The processed picture was then transformed into a binary mask using the same lower

520   threshold value as in the first step. This binary mask was then projected onto the original

521   unmodified image using the "min" operation from the ImageJ image calculator. For spots/µm²

522   the number of spots was divided by the size of the mask of the synaptic area.

523   For colocalization analysis (Pearson correlation coefficient) the ImageJ plugin "JACOP"

524   (http://rsb.info.nih.gov/ij/plugins/track/jacop2.html) was used. To determine the synaptic protein

525   levels, a custom-written ImageJ script was used that detects the locations with highest local

526   maxima in pixel values to generate regions of interests (ROIs) and sets a point selection at each.

527   The intensities were then measured and all selections were deleted, leaving intensity values and

528   (x,y) locations in the results list. The results list was then used to create a circle of size = 5 pixels

529   (pixel size 100 nm) centered around each (x,y) location and the integrated density within these

530   ROIs was measured and taken for further calculations. The same ROIs were then used in the

531   channel containing signals of the co-stained protein. For scatter plots, co-stainings of BRP either

25

532 with RBP, Unc13A or Syx-1A with or without PhTx-treatment or Wild-type and *gluRIIA*[Null]

533 were used. The AZ numbers were counted (number of BRP spots) and the local synaptic levels

534 of both co-stained proteins were measured. AZs were then sorted into five bins (AZ number

535 divided by five) depending on their synaptic BRP levels and then the respective second channel

536 intensities distributed to the appropriate bin. Binned BRP levels were then plotted against binned

537 levels of the second channel.

538

539 **STED Microscopy**

540 Two-color STED images were recorded on custom-built STED-microscopes[89, 90], which either

541 combine two pairs of excitation laser beams of 595 nm and 635 nm or 595 nm and 640 nm

542 wavelength with one STED fiber laser beam at 775 nm. All STED images were acquired using

543 Imspector Software (Max Planck Innovation GmbH, Germany). STED images were processed

544 using a linear deconvolution function integrated into Imspector Software (Max Planck

545 Innovation GmbH, Germany). Regularization parameters ranged from $1e^{-09}$ to $1e^{-10}$. The point

546 spread function (PSF) for deconvolution was generated by using a 2D Lorentz function with its

547 half-width and half-length fitted to the half-width and half-length of each individual image. For

548 Fig. 3C, dual-color STED imaging with time-gated detection was performed using a commercial

549 Leica SP8 TCS STED microscope (Leica Microsystems, Germany) equipped with a 100x NA

550 1.4 objective (HC PL Apo CS2; Leica Microsystems, Germany). Briefly, the system includes an

551 inverted DMi8 CS microscope equipped with a 100x pulsed white light laser (WLL; ~80-ps

552 pulse width, 80-MHz repetition rate; NKT Photonics, Denmark) with a STED lasers for

553 depletion (pulsed) at 775 nm. Detection of Alexa594 after excitation at 594 nm and emission

554 detection of 604-650 nm and Atto647 after excitation at 640 nm at emission of 656 – 751 nm

555   was performed in frame sequential mode. Time-gated detection with Hybrid detectors was set

556   from 0.3–6 ns for both dyes. Raw data were deconvolved with Huygens Professional software

557   (Scientific Volume Imaging) using a theoretical point spread function automatically computed

558   based on pulsed-wave STED optimized function and the specific microscope parameters. Default

559   deconvolution settings were applied. Images for figures and for finding high-intensity clusters

560   (see below) were processed with ImageJ software to remove obvious background or neighboring

561   AZs (if required), enhance brightness/contrast and smoothened (0.5 pixel Sigma radius) using the

562   Gauss blur function.

563

564   **Classification and Alignment of Single AZs**

565   All analysis described below was done using MATLAB R2016b (Mathworks Inc., MA, USA)

566   with optional toolboxes, which are indicated in the respective sections. Classification of

567   individual AZs was achieved by using a custom script to detect the position of cluster centers

568   (local intensity maxima) in the images where obvious background was removed (only for

569   Unc13A, BRP, RBP), while the averaging procedure described hereafter was performed on

570   unretouched images. This code retains only pixels above a defined grey value threshold. For the

571   analysis of Unc13A stainings shown in Fig. 2f, a threshold value of 25 was used (18 for BRP,

572   RBP, Syx-1A and Unc-18). All pixel values in the image below this threshold value were set to

573   zero to remove background noise. We then identified the positions of high-intensity pixel

574   clusters as local intensity maxima in the images freed from neighboring AZ signal and obvious

575   noise. This was achieved by finding local maxima in the vertical and horizontal pixel lines. First,

576   the function searched the first derivative (using the function *diff*) of all pixel columns for zero

577   values and the changes in the surrounding slopes were considered to identify local maxima. The

578   same procedure was then applied in pixel rows, but only for those pixel column values associated

579   with a local maximum in the previous step. All single pixels that were associated with a

580   maximum in both a row and a column were detected using the function *intersect*. To prevent

581   detection of the same cluster more than once, a defined minimum distance of clusters was used

582   (50 nm for BRP, Unc13A, Syx-1A and RBP, 20 nm for RBP) and only the local maximum with

583   the highest intensity value was considered. All subsequent translation and averaging procedures

584   were performed on the non-cleaned images of the same AZs using the determined classification

585   and positions of clusters. The non-cleaned AZs were sorted by the number of protein clusters

586   detected this way. To calculate the center of mass of all coordinates, the means of all x- and y-

587   coordinates were taken according to equations (1) and (2).

588    $\quad$ (1) $Sx = n^{-1} \cdot \sum_{1}^{n} x_{obs}(n)$

589    $\quad$ (2) $Sy = n^{-1} \cdot \sum_{1}^{n} y_{obs}(n)$

590   Where (Sx,Sy) is the (x,y)-coordinate center of mass in the initial image, n is the number of

591   identified clusters, and $x_{obs}(n)$ and $y_{obs}(n)$ are the positions of the nth cluster in the present image.

592   To align the center of mass to the center of the image, the necessary shift (Δx and Δy) of the

593   original coordinates was calculated according to equations (3) and (4) and used subsequently in

594   equations (5) and (6).

595    $\quad$ (3) $\Delta x = 0.5 \cdot imsize(x) - Sx$

596    $\quad$ (4) $\Delta y = 0.5 \cdot imsize(y) - Sy$

597    $\quad$ (5) $x_{centered}(n) = x_{obs}(n) + \Delta x$

598    $\quad$ (6) $y_{centered}(n) = y_{obs}(n) + \Delta y$

599   In equations (3) and (4), "imsize" refers to the size of the image in x or y dimension. The

600   resulting coordinates $x_{centered}$ and $y_{centered}$ represent cluster coordinates after shifting the original

601   coordinates x_{obs} and y_{obs}. The same translation was applied to the corresponding AZ image (using

602   the function *imtranslate*, part of the 'Image Processing' toolbox). Clusters were ranked in a

603   counter-clockwise sequence in all images (see illustration in Fig. 2b; Supplementary Fig. 3c) by

604   sorting them for increasing angle between the image center and the cluster location in relation to

605   the vertical midline (x=26).

606   To align protein cluster coordinates between all investigated AZs, central rotation (around

607   the image center, $x_{middle}=y_{middle}=26$), was done using the operation in equation (7).

608   (7) $\begin{pmatrix} x_{rotated}(n) \\ y_{rotated}(n) \end{pmatrix} = \left[\begin{pmatrix} x_{centered}(n) \\ y_{centered}(n) \end{pmatrix} - \begin{pmatrix} x_{middle} \\ y_{middle} \end{pmatrix} \right] \cdot \begin{pmatrix} \cos(\alpha) & -\sin(\alpha) \\ \sin(\alpha) & \cos(\alpha) \end{pmatrix} + \begin{pmatrix} x_{middle} \\ y_{middle} \end{pmatrix}$

609   To find the optimal angle to overlay all AZs, a cost reflecting the sum of distances between

610   cluster positions of the same rank in all images was minimized. The cost function was defined as

611   described in equation (8).

612   (8) $cost = \sum_{n=1}^{totClusters} \sum_{m=1}^{totImgs} \sum_{l=1}^{totImgs} ((x_{rotated}(n,m) - x_{rotated}(n,l))^2 +$

613       $(y_{rotated}(n,m) - y_{rotated}(n,l))^2)$

614   In equation (8), *n* is the cluster number, *totClusters* is the total cluster number of the respective

615   category of images, *m* and *l* are particular AZ images in the stack of images from one category,

616   and *totImgs* is the total number of AZ images in that category. The squared Euclidean distances

617   were found by using the function *pdist*.

618   The optimal rotation angle was found using a genetic algorithm function (*ga*, part of the

619   'Global Optimization' toolbox). The rotation angles evaluated were constrained in a range from -

620   180 to 180 degrees. For faster optimization, parallelization (setting the option 'UseParallel' to

621   'true'; this requires the 'Parallel Computing' toolbox) was employed to evaluate 500 individual

622   cost functions per generation. Cluster coordinates from all images in one category were rotated

623 simultaneously. A single individual in the genetic algorithm represented a set of rotation angles

624 for each image. The convergence criterion (*TolFun*) was left at the default value (a relative cost

625 value change of less than 10^{-6} over 50 generations). The output of this optimization was a vector

626 containing all rotation angles that led to the best overlap of cluster coordinates. Finally, these

627 rotations were then applied to the centered original AZ images. All images aligned this way were

628 then combined in a stack and an average image was generated by calculating the mean intensity

629 of all image pixels. For better illustration of the AZ structure, pixel intensities were linearly

630 scaled such that the highest intensity pixel had a value of 255. The procedure was only

631 performed if more than two images existed in the same cluster number class for at least 5

632 consecutive cluster number classes. The histograms shown in Fig. 2c,d,e and supplementary Fig.

633 2a were generated by counting the number of images in each cluster number class, and dividing

634 each value by the total amount of images detected in all classes. The mean cluster intensity was

635 calculated by taking the differences between the mean image intensities in consecutive classes,

636 and averaging them.

637 To investigate the AZ structure in an approach independent of the cluster-distance

638 minimization procedure described above, we repeated the averaging in a different way as

639 follows. We developed a MATLAB code for AZ centering and alignment by rotation of the

640 highest intensity pixel to identical angles and therefore similar positions, which yielded

641 qualitatively similar results (Supplementary Fig. 3a). Again, high-intensity clusters were found in

642 AZ images cleaned from obvious noise and bordering AZs, and all translations and rotations

643 were then performed on unretouched images. The center of mass of the found cluster coordinates

644 was calculated and the image shifted so that the center of mass of the coordinates was in the

645 center of the 51 by 51 pixel space (x=y=26; see equations (1) to (6)). The brightest point in each

646   image was then found by sorting the list of intensities of all clusters found. Only this point was

647   then considered for rotation. To determine the angle by which to rotate each image to place this

648   highest intensity region to the same fixed position (on the vertical midline between the two top

649   image quadrants), the x and y distances to the center of rotation (equal to the center pixel of the

650   image x=y=26) were calculated to find the length (*l*) of the hypotenuse and the opposite side of

651   the right triangle. The angle α in degrees was then calculated by taking the inverse sine in

652   degrees of this value (MATLAB function *asind*), as shown in equation (9).

653   (9) $\alpha = \sin^{-1}\left(\frac{l_{opposite\ side}}{l_{hypotenuse}}\right)$

654   In cases where the brightest peak was located above the horizontal midline, the adjacent side of

655   the triangle was the vertical midline. In cases where the brightest peak was located below the

656   horizontal midline, the angle was calculated with the horizontal midline being the adjacent side,

657   and 90° were added to the final angle value. Additionally, in cases where the brightest peak was

658   located to the right of the vertical midline, the angle was multiplied with -1. To generate the

659   results shown in Supplementary Fig. 3b, which shows the averaging of AZ images within

660   randomly assigned categories, we generated a number of random category values and then

661   proceeded with the averaging procedure described above. For this, we reproduced the

662   distribution of category values from the AZ dataset according to the histogram values of the

663   category vector as follows. A histogram of the category vector was generated (MATLAB

664   function *histogram*) with a bin width of 1, yielding the absolute amount of AZs per category. A

665   cumulative   sum   vector   was   calculated   from   these   histogram   values   (MATLAB

666   function *cumsum)*. For each position in the category vector, we then chose a random number

667   between 0 and 1 and multiplied it by the number of images considered in the category vector. We

668   then found the first position in the cumulative sum vector that was larger than this random value.

669   The position found was equal to the assigned category. This resulted in a randomly assigned

670   category vector with a similar distribution of categories as the original vector.

671

672   ***In vivo* live imaging and analysis**

673   *In vivo* imaging of intact *Drosophila* larvae was performed as previously described[91]. Briefly, 3rd

674   instar larvae were put into a drop of Voltalef H10S oil (Arkema, Inc., France) within an airtight

675   imaging chamber. Before imaging, the larvae were anaesthetized with 20 short pulses of a

676   desflurane (Baxter,IL, USA) air mixture until the heartbeat completely stopped. For assessing

677   axonal transport, axons immediately after exiting the ventral nerve cord were imaged for 5 min

678   using timelapse confocal microscopy. Kymographs were plotted using a custom-written ImageJ

679   script.

680

681   **Dissection, Induction of Homeostatic Plasticity and Electrophysiology**

682   Third-instar larvae were selected and placed individually on a Sylgard block. Using a very sharp

683   pin, the tail of the larva was pinned between the posterior spiracles, in the absence of solution.

684   The head was pinned, making sure not to stretch the larva, so that the animal was relatively loose

685   between the two pins. A small horizontal incision was made in the dorsal cuticle at the tail with a

686   sharp scissors. The larva was cut vertically from the tail incision in an anterior direction (towards

687   the head), continuing beyond the head pin. Great care was taken not to stretch the cuticle or

688   animal during this process. 40 µl of a 20 µM PhTx in modified hemolymph-like solution (HL3;

689   [92] composition (in mM): NaCl 70, KCl 5, $MgCl_2$ 10, $NaHCO_3$ 10, trehalose 5, sucrose 115,

690   HEPES 5, $CaCl_2$ 0, pH adjusted to 7.2) was pipetted into the abdominal cavity with minimal

691   force, making sure to fill the abdomen. After 10 minutes incubation, the preparation was

692   completed without rinsing. The cuticle was gently pinned twice on each side (without

693   stretching). The connection of the intestines and trachea to the body at the posterior were cut.

694   Holding the now free ends of the intestines and trachea with a fine forceps, remaining

695   connections were cut moving in an anterior direction (towards the head). The intestines and

696   trachea could then be gently removed without stretching the larva. Finally, the brain was held

697   firmly and slightly raised above the body so that the scissors could be placed underneath to cut

698   the segmental nerves. Care was taken not to touch the underlying muscle and to avoid excessive

699   pulling of the nerves before they were cut. The completed preparation was rinsed 3 times with

700   PhTx-free HL3 (0 mM $CaCl_2$, 10 mM $MgCl_2$). PhTx-free HL3 solution was used in control

701   treatments. Sylgard blocks were kept separate for PhTx and control treatments and all

702   implements were rinsed after each recording.

703   The Sylgard block and completed larval preparation was placed in the recording chamber

704   which was filled with 2 ml HL3 (0.4 mM $CaCl_2$, 10 mM $MgCl_2$). Recordings were performed at

705   room temperature (~22°C) in current clamp mode at muscle 6 in segments A2/A3 as previously

706   described[93] using an Axon Digidata 1550A digitizer, Axoclamp 900A amplifier with HS-9A x0.1

707   headstage (Molecular Devices, CA, USA) and on a BX51WI Olympus microscope with a 40X

708   LUMPlanFL/IR water immersion objective. Sharp intracellular recording electrodes were pulled

709   using a Flaming Brown Model P-97 micropipette puller (Sutter Instrument, CA, USA) with a

710   resistance of 20-35 MΩ, back-filled with 3 M KCl. Cells were only considered with a membrane

711   potential less than -60 mV and membrane resistances greater than 4 MΩ. All recordings were

712   acquired using Clampex software (v10.5) and sampled at 10-50 kHz, filtering with a 5 kHz low-

713   pass filter. mEPSPs were recorded for 1 minute. eEPSPs were recorded by stimulating the

714   appropriate nerve at 0.1 Hz, 5 times (8 V, 300 µs pulse) using an ISO-STIM 01D stimulator (NPI

33

715 Electronic, Germany). Stimulating suction electrodes were pulled on a DMZ-Universal Puller

716 (Zeitz-Instruments GmbH, Germany) and fire polished using a CPM-2 microforge (ALA

717 Scientific, NY, USA). A maximum of two cells were recorded per animal.

718   Analysis was performed with Clampfit 10.5 and Graphpad Prism 6 software. mEPSPs were

719 further filtered with a 500 Hz Gaussian low-pass filter. Using a single template for all cells,

720 mEPSPs were identified and analyzed, noting the mean mEPSP amplitude per cell. For Fig. 5

721 and Supplementary Fig. 7, templates were generated for each cell and the first 30 mEPSPs were

722 identified and taken into account for further analysis. An average trace was generated from the 5

723 eEPSP traces per cell. The amplitude of the average eEPSP trace was divided by the mean

724 mEPSP amplitude, for each respective cell, to determine the quantal content.

725   Dissection and current clamp recordings of w1118 vs *gluRIIA*^{Null} were performed as above

726 in male third-instar larvae. Cells with an initial membrane potential greater than -55 mV,

727 resistances less than 5 MΩ or multiple responses to a single stimulus were rejected. eEPSPs were

728 recorded by stimulating the appropriate nerve at 0.2 Hz, 10 times (6 V, 300 µs pulse). An

729 average eEPSP amplitude was calculated from the 10 traces. mEPSPs were analysed with a

730 genotype specific template. Quantal contents were calculated by dividing the mean eEPSP by

731 mean mEPSP for each cell.

732

733 **In Vivo Two-Photon Live Calcium Imaging and Analysis**

734 Two-photon imaging of odor-evoked calcium responses was conducted in 3 to 5-day-old mixed-

735 sex flies expressing LexAop-GCaMP6f in VT1211-LexA. For imaging, flies were briefly

736 anesthetized on ice and mounted in a custom made chamber by immobilizing wings, head and

737 proboscis with wax. The head capsule was opened in sugar-free HL3-like extracellular saline[94].

738   Odor stimulation consisted of a 1.5 s OCT pulse followed by a 30 s break and then a 1.5 s MCH

739   pulse followed again by another 30 s break. This alternating odor pulse protocol was

740   consecutively repeated five times (odor dilution in mineral oil 1/1000). Odors were delivered on

741   a clean air carrier stream and image acquisition and odor stimulation was synchronized

742   temporally using a custom-designed system. Fluorescence was centered on 910 nm generated by

743   a Ti-Sapphire laser (Chameleon Ultra II, Coherent, CA, USA). Images with a pixel size of 0.3 x

744   0.3µm were acquired at 70 Hz using two-photon microscopy (Femto2D-Resonant by Femtonics

745   Ltd., Hungary) with a 20X, 1.0 NA water-immersion objective, controlled by MESc v3.5

746   software (Femtonics Ltd., Hungary). For each animal, a single hemisphere was analyzed. All

747   OCT and MCH responses of a fly were averaged respectively and resulting traces were averaged

748   between flies. Mean intensity values of two-photon fluorescence were calculated, while F0 was

749   defined as the mean F from 0 to 1.5s at the beginning of a recording (MESc v 3.5 software).

750   Image processing for single frames were manually performed using ImageJ (images did not

751   require registration).

752

753   **Odor avoidance conditioning**

754   All flies were 3 to 5 days old, raised in 12 h:12 h, light:dark cycle and at 65% relative humidity.

755   One day before the experiment, the flies were transferred to fresh food vials. One hour prior to

756   the experiment, flies were pre-conditioned to experimental conditions (dim red light, 25°C,

757   humidity of 80%). The aversive odors 3-Octanol (OCT) and Methylcyclohexanol (MCH) were

758   diluted 1:100 in paraffin oil and presented in 14 mm cups. A current of 120V AC was used as a

759   behavioral reinforcer. The associative training was performed as previously described[95]. In a

760   single-cycle training, nearly 100 flies were presented with one odor (CS$^+$) paired with electrical

761 shock (US; 12 times for one minute). After one minute of pure air-flow, the second odor was

762 presented without the shock (CS⁻) for another minute. The flies were then immediately tested for

763 short-term memory performance by presenting them the two odors together. A performance

764 index (PI) was calculated as the number of flies choosing the odor without shock (CS⁻), minus

765 the number of flies choosing the odor paired with shock (CS⁺), divided by the total number of

766 flies, multiplied by 100. The values of PI ranges from 0 to 100 where 0 means no learning (50:50

767 distribution of flies) and a value of 100 means complete learning (all flies avoided the

768 conditioned odor). The final learning index was calculated as the average of both reciprocal

769 indices for the two odors. Odor Avoidance experiments were used to test innate behavior where

770 each odor was presented to the flies without conditioning. The PIs were calculated as stated

771 above.

772

773 **Quantification and Statistical Analysis**

774 Data were analyzed using Prism (GraphPad Software, CA, USA). Per default Student's t test was

775 performed to compare the means of two groups unless the data were either non-normally

776 distributed (as assessed D'Agostino-Pearson omnibus normality test) or if variances were

777 unequal (assessed by F test) in which case they were compared by a Mann-Whitney U Test.

778 However, in supplementary table 1 both tests are provided for all relevant cases. For comparison

779 of more than two groups, one-way analysis of variance (ANOVA) tests were used, followed by a

780 Tukey's multiple comparison test. P values and N values are given in Supplementary table 1.

781 Means are annotated ± s.e.m.. Asterisks are used to denote significance: *, $p < 0.05$; **, $p < 0.01$;

782 ***, $p < 0.001$; n.s. (not significant), $p > 0.05$.

783

784 **Data and Software Availability**

785 The data that support the findings of this study as well as MATLAB and ImageJ codes used in

786 this study are available from Alexander M. Walter (awalter@fmp-berlin.de) upon request.

787

788 **Contact for Reagent and Resource Sharing**

789 Informations and requests for resources and reagents should be directed to and will be fulfilled

790 by the Lead Contact, Alexander M. Walter (awalter@fmp-berlin.de).

1025

1026   **Author Contributions:**

1027   M.A.B, S.J.S and A.M.W conceived the project. M.A.B., A.W.M., C.B.B., P.G. and A.G.P.

1028   performed fly husbandry and maintenance. M.A.B., M.J., M.L. and P.G. performed confocal

1029   and/or STED imaging experiments and M.A.B., P.G. and A.T.G. analyzed the data. A.W.M.,

1030   M.J. and P.G. performed electrophysiological experiments and analyzed the data. U.R.

1031   performed live-imaging experiments and analysis. P.H. provided reagents and suggested

1032   additional experiments. A.T.G and A.M.W. developed software codes for image alignment and

1033   averaging and A.T.G analyzed the data. P.G. and D.D. conceived and performed translation

1034   block experiments. C.B.B. performed adult *Drosophila* brain antibody staining and imaging.

1035   C.B.B. and S.H. performed behavioral experiments and data analysis. S.H. performed Western

1036   blots. D.L. and D.O. planned and performed in vivo two-photon live calcium imaging. F.G. and

1037   S.W.H. developed and built the STED microscope. M.A.B., S.J.S, and A.M.W wrote the paper
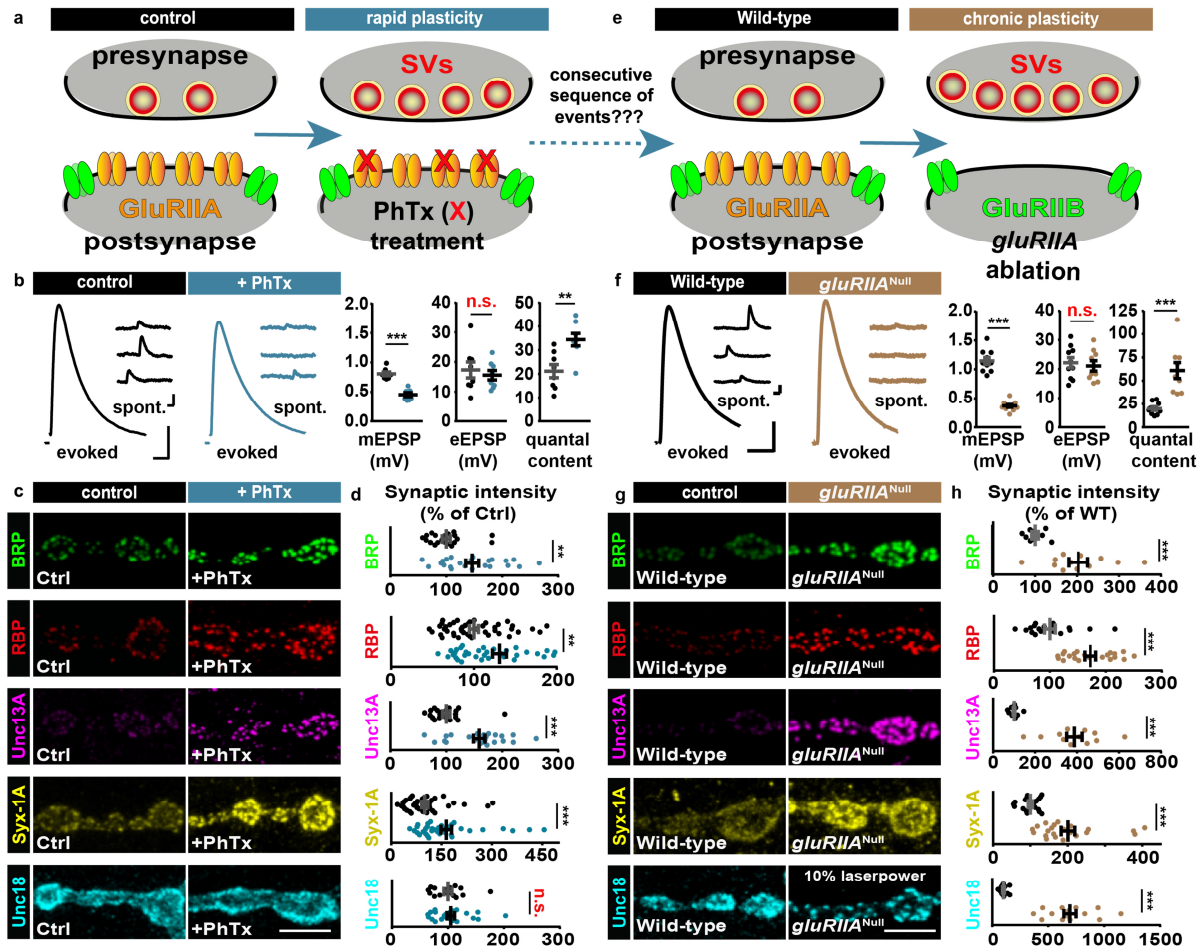

1038   with input from all co-authors.

1039

1040   **COMPETING INTERESTS**

1041   All authors declare no conflicting financial and non-financial interest.

1042

1043 **Main Figures and Legends**

1044 **Figure 1**

1045

1046 **Figure 1: Rapid homeostatic plasticity regulates AZ protein levels.**

1047 **(a)** Sketch of investigated conditions for rapid plasticity: control synapses (left) are compared

1048 with rapid plasticity (10 minutes of PhTx (red "X"); right). Rapid plasticity increases the number

1049 of SVs released (red). **(b,f)** Representative traces of eEPSP (evoked), mEPSP (spont.) and their

1050 quantification in Ctrl (black) and PhTx (blue) treated (b) or wild-type (black) and $gluRIIA^{Null}$

1051 (brown) (f) cells. **(c,g)** NMJs labelled with indicated antibodies in Ctrl (black) and PhTx (blue)

1052 treated (c) or in wild-type (black) and $gluRIIA^{Null}$ (brown) (g) animals. **(d, h)** Quantification of

1053 BRP, RBP, Unc13A, Syx-1A and Unc18 AZ-levels in % of Ctrl in Ctrl (black) and PhTx (blue)

45

1054   treated (d) or in % of Wild-type (WT) in Wild-type (black) and *gluRIIA^Null* (brown) (h) animals.

1055   **(e)** Sketch of investigated conditions for chronic plasticity: Wild-type synapses (left) are

1056   compared with *gluRIIA^Null* mutants. Chronic plasticity greatly increases the number of SVs

1057   released. See also Supplementary Fig. 1. Exact normalized and raw values, detailed statistics

1058   including sample sizes and P values are listed in Supplementary Table 1. Scale bars: (b,f) eEPSP:

1059   25 ms, 5 mV; mEPSP: 50 ms, 1 mV; (c,g) 5 µm. Statistics: Student's unpaired T-test was used

1060   for comparisons in (b) and (f) mEPSP amplitude, quantal content and Mann-Whitney U test for

1061   all other comparisons. **P ≤ 0.01; ***P ≤ 0.001; n.s., not significant, P > 0.05. All panels show

1062   mean ± s.e.m.

1063

1064   **Figure 2**
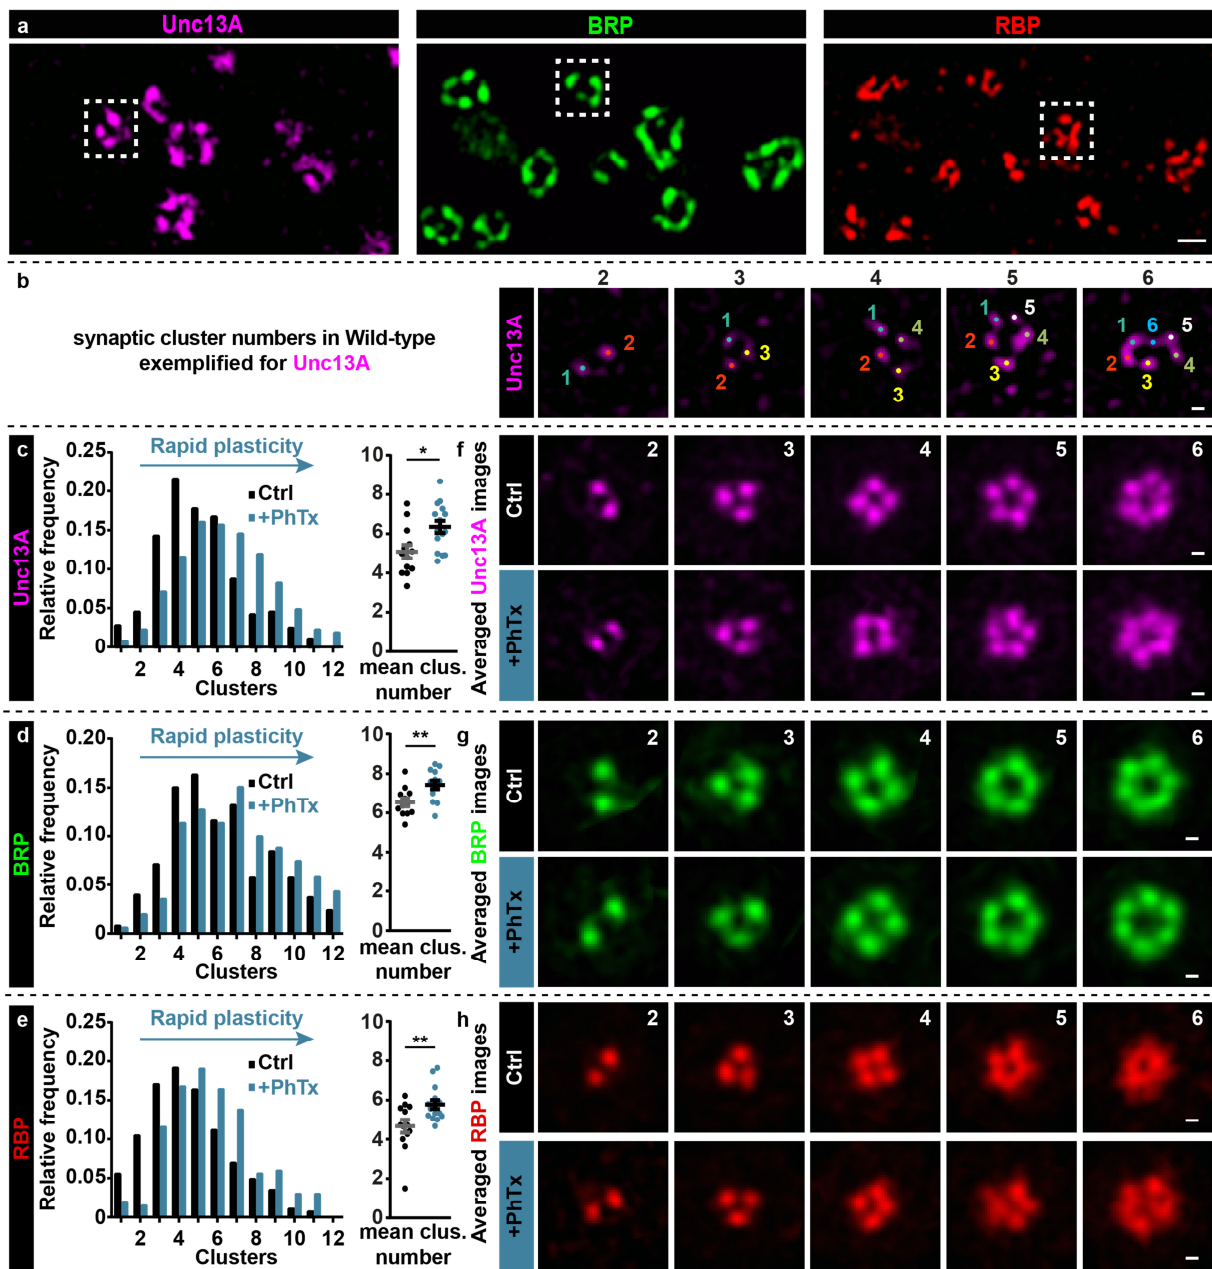

1065

1066   **Figure 2: Rapid plasticity alters Unc13A/BRP/RBP AZ protein cluster number.**

1067   **(a)** STED microscopy images containing several AZs with variable numbers of protein clusters

1068   of Unc13A (magenta); BRP (green) and RBP (red). Dashed white boxes mark one AZ example

1069   used for the cluster number counting. **(b)** Example AZs with 2-6 Unc13A clusters, marked by

1070   colored dots and used for cluster number counting. **(c-e,** left**)** Frequency distribution of Unc13A

1071   (c), BRP (d) and RBP (e) modules per AZ either without (Ctrl, -PhTx; black) or with PhTx

1072   (+PhTx; blue) treatment. **(f-h)** Average of rotated STED images stained against Unc13A (f),

1073   BRP (g) and RBP (h) with 2-6 modules either without (Ctrl) or with PhTx (+PhTx) treatment.

1074   See also Supplementary Figs. 2-4. Exact values, detailed statistics including sample sizes and P

1075   values are listed in Supplementary Table 1. Scale bars: (a) 200 nm; (b,f-h) 50 nm. Statistics:

1076   Mann-Whitney U test. n.s., not significant, $P > 0.05$. Panels (c-e) show NMJ-wise means of AZ-

1077   mean $\pm$ s.e.m.

1078

1079   **Figure 3**
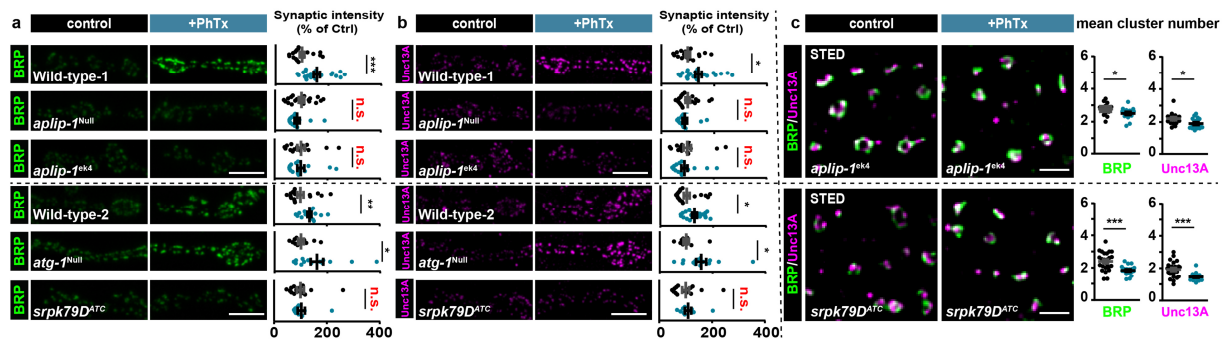

1080

1081   **Figure 3: Rapid AZ-remodeling during homeostatic plasticity requires Aplip-1 and**

1082   **Srpk79D.**

1083   **(a,b)** Muscle 4 NMJs of segment A2-A5 from 3rd instar larvae and quantification of synaptic

1084   levels of Wild-type – 1, *aplip-1*[Null], *aplip-1*[ek4], Wild-type – 2, *atg1* and *srpk79D*[ATC] labelled with

1085   the indicated antibodies without (Ctrl; black) and with 10 minutes of PhTx (+PhTx; blue)

1086   treatment. Two independent experiments were performed, Wild-type – 1 was used as control for

1087   *aplip-1*[Null] and *aplip-1*[ek4] while Wild-type – 2 was used for *atg1*[Null] and *srpk79D*[ATC]. **(c)** Average

1088   BRP and Unc13A cluster number per AZ either without (Ctrl, -PhTx; black) or with PhTx

1089   (+PhTx; blue) treatment in *aplip-1*[ek4] and *srpk79D*[ATC]. See also Supplementary Figs. 5, 6 and

1090   Movie 1. Exact normalized and raw values, detailed statistics including sample sizes and P

1091   values are listed in Supplementary Table 1. Scale bars: (a,b) 5 μm; (c) 500nm. Statistics: Mann-

1092   Whitney U test. * $P \leq 0.05$; **$P \leq 0.01$; ***$P \leq 0.001$; n.s., not significant, $P > 0.05$. All panels
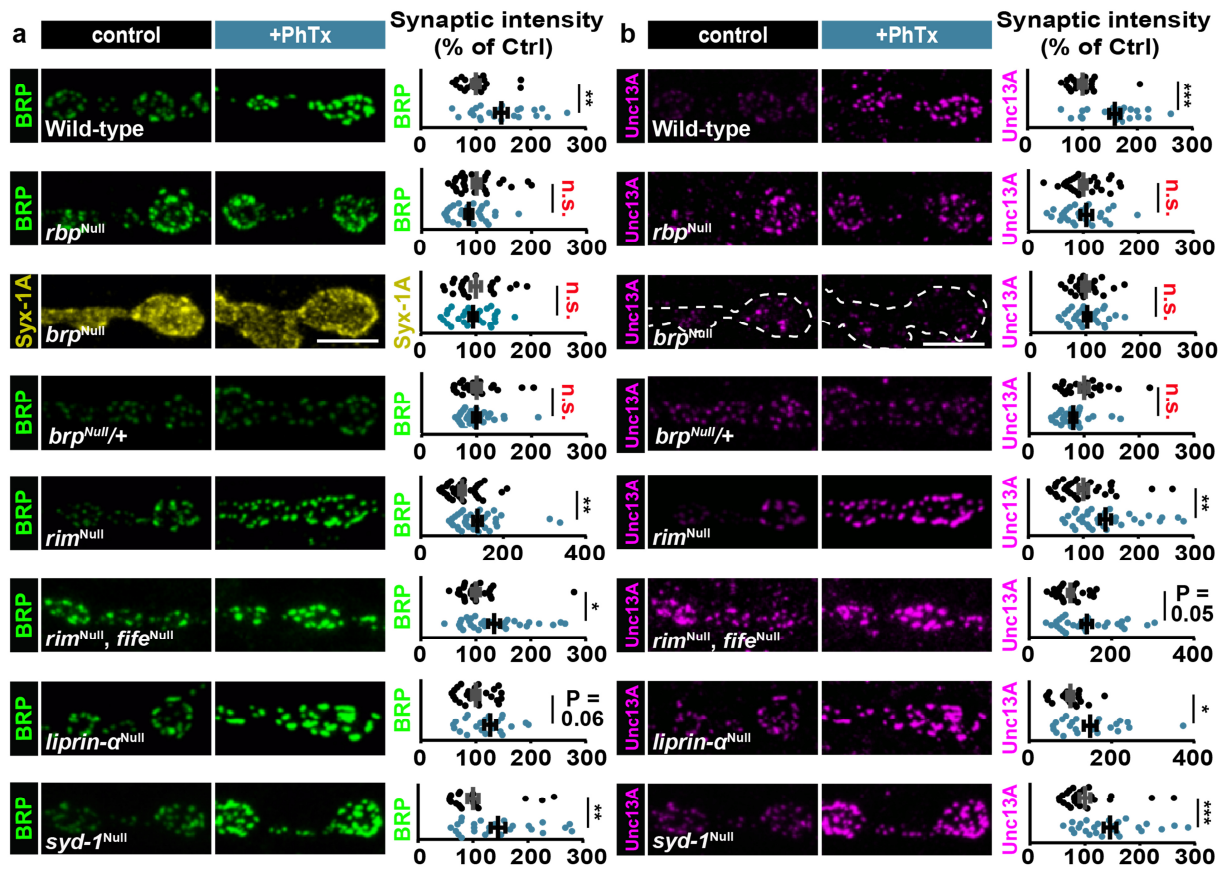

1093   show mean ± s.e.m.

1094

1095

1096

1097

49

1098 **Figure 4**

1099

1100 **Figure 4: Rapid AZ-remodeling during homeostatic plasticity requires BRP and RBP.**

1101 **(a,b)** Confocal images and quantification of synaptic intensities of muscle 4 NMJs of abdominal

1102 segment 2-4 from 3rd instar larvae at Wild-type,, rbp^{Null}, brp^{Null}, $brp^{Null}/+$, rim^{Null}, rim^{Null} $fife^{Null}$,

1103 $liprin$-α^{Null} and $syd1^{Null}$ NMJs labelled with the indicated antibodies without (control; black) and

1104 with 10 minutes PhTx (+PhTx; blue) treatment. For Wild-type, images and data were adapted

1105 and replotted from Fig. 1. Please note, although Wild-type controls were performed in parallel to

1106 every mutant genotype to check for functional AZ-remodeling upon PhTx-treatment in each set

1107 of experiments, we do not show all WT-control here due to space limitations. Therefore, AZ-

1108 protein levels should not be compared between genotypes. Exact normalized and raw values

1109 (also of additional Wild-type controls for genotypes where PhTx-treatment failed to induce AZ-

50

1110   remodeling), detailed statistics including sample sizes and P values are listed in Supplementary

1111   Table 1. Scale bars: 5 µm. Statistics: Mann-Whitney U test. * $P \leq 0.05$; **$P \leq 0.01$; ***$P \leq$

1112 0.001; n.s., not significant, $P > 0.05$. All panels show mean ± s.e.m.

1113   **Figure 5**
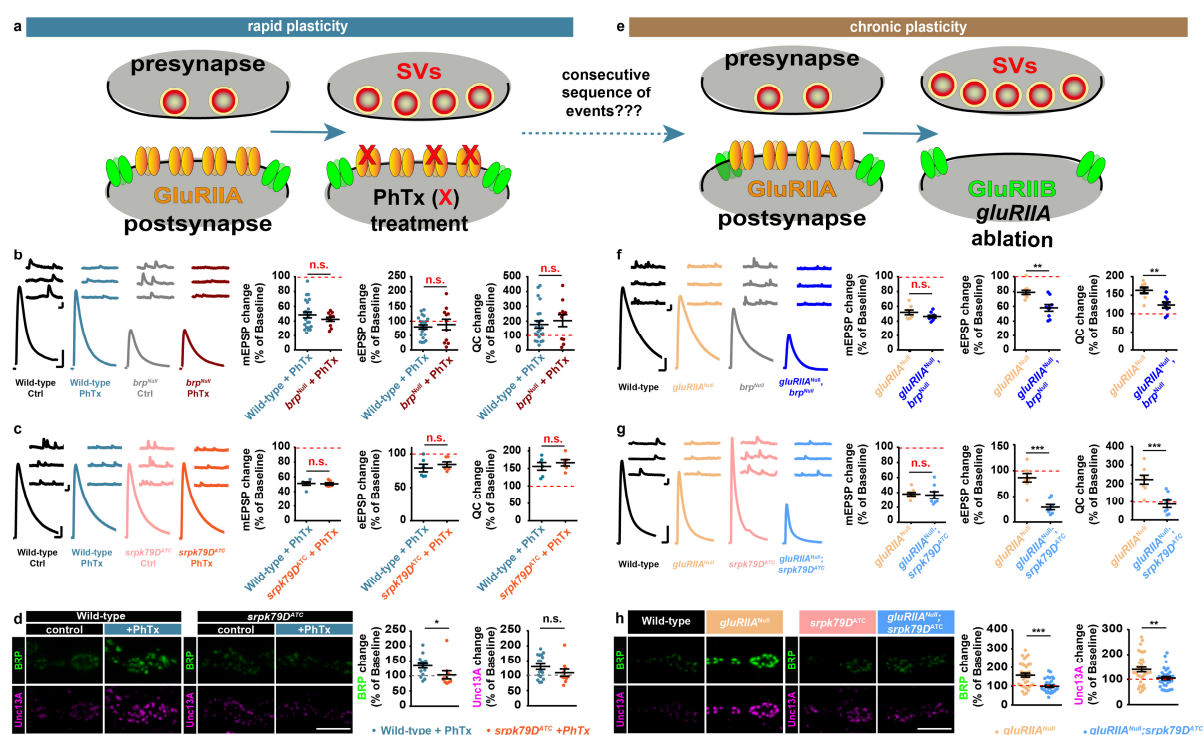

1114

1115   **Figure 5: Structural AZ-remodeling sustains NT-release potentiation over longer**

1116   **timescales.**

1117   **(a)** Sketch of investigated conditions for rapid plasticity: control synapses (left) are compared

1118   with rapid plasticity (10 minutes of PhTx (red "X"); right). Rapid plasticity increases the number

1119   of SVs released (red). **(b,c)** (left) Representative traces of eEPSP (evoked) and mEPSP (spont.)

1120   of the indicated genotypes with and without PhTx-treatment. (Right) Quantifications of

1121   percentage change of mEPSP amplitude, eEPSP amplitude and quantal content (QC) upon PhTx-

1122   treatment. Values are divided by the corresponding measurement in the absence of PhTx for each

1123   genotype (dashed red line corresponds to 100%/no change). **(d)** (left) Confocal images of muscle

1124   4 NMJs of abdominal segment 2-5 from 3rd instar larvae at Wild-type and $srpk79D^{ATC}$ NMJs

1125   labelled with the indicated antibodies without (control; black) and with 10 minutes PhTx

1126   (+PhTx; blue) treatment. (Right) Quantification of percentage change of synaptic BRP and

52

1127   Unc13A levels in Wild-type (blue) and *srpk79D*^{ATC} (orange) upon PhTx-treatment compared to

1128   baseline of control treatment for each genotype (dashed red line). Data are modified from Fig. 2.

1129   **(e)** Sketch of investigated conditions for chronic plasticity: Wild-type synapses (left) are

1130   compared with *gluRIIA*^{Null} mutants. Chronic plasticity greatly increases the number of SVs

1131   released. **(f,g)** Same as in (b,c) but compared to baseline of each control genotype. **(h)** Same as in

1132   (d) but compared to baseline fluorescence values of Wild-type for *gluRIIA*^{Null} and *srpk79D*^{ATC}

1133   for *gluRIIA*^{Null};*srpk79D*^{ATC}. See also Supplementary Fig. 7. Exact normalized and raw values,

1134   detailed statistics including sample sizes and P values are listed in Supplementary Table 1. See

1135   also Supplementary Figure 10 and 11 for non-normalized values. Scale bars: eEPSP: 25 ms, 5

1136   mV; mEPSP: 50 ms, 1 mV; (d,h) 5 μm. Statistics: Student's unpaired T-test was used for

1137   comparisons in (b) mEPSP change, (f), (g) and Mann-Whitney U test for all other comparisons.

1138   *P ≤ 0.05; **P ≤ 0.01; ***P ≤ 0.001; n.s., not significant, P > 0.05. All panels show mean ±

1139   s.e.m.

1140   **Figure 6**
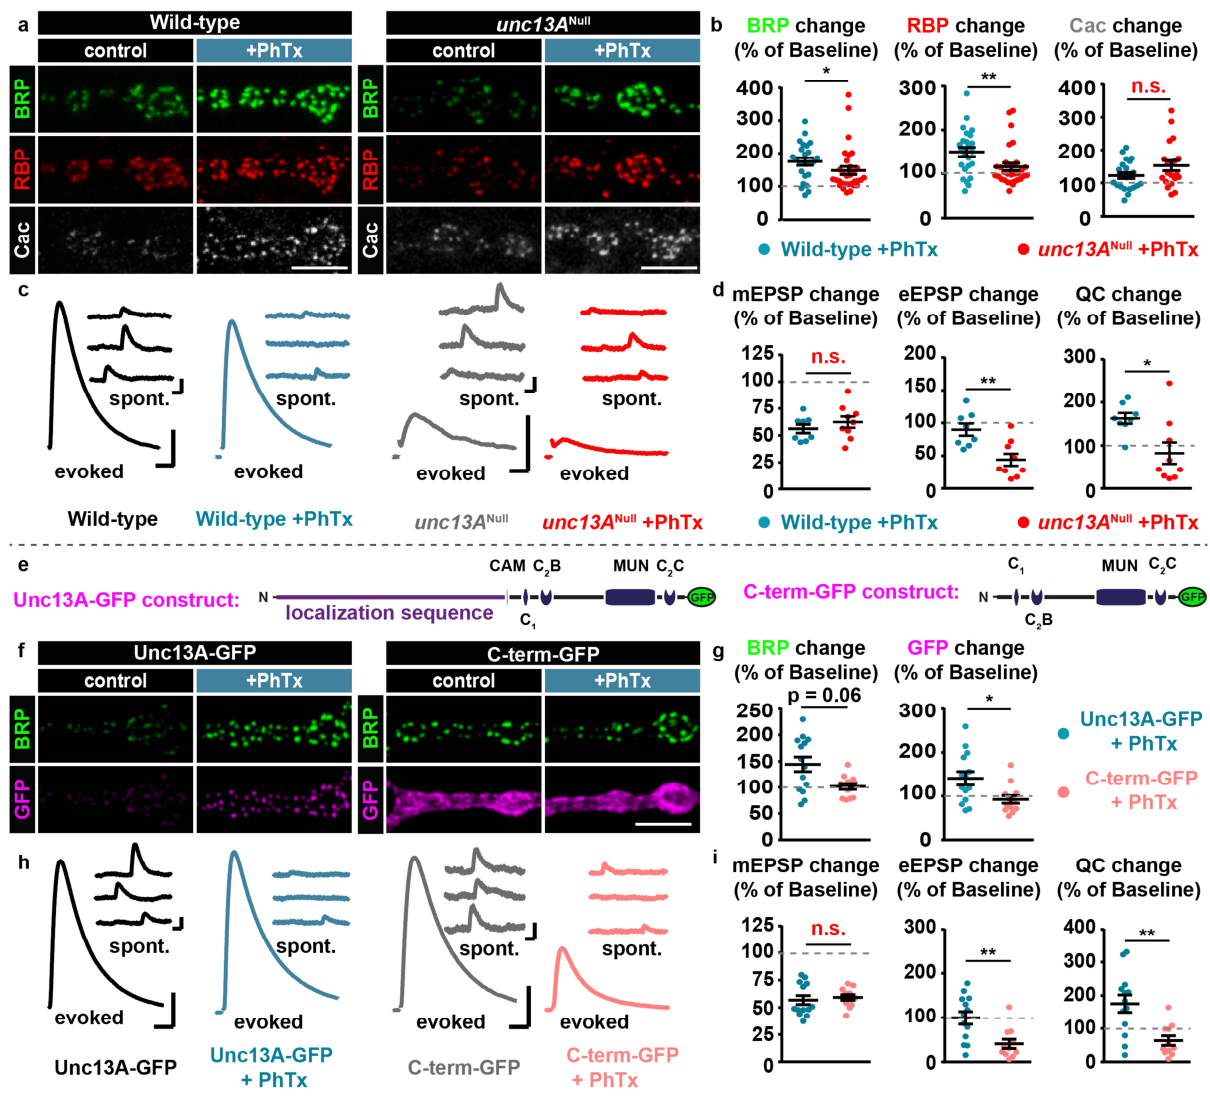

1142   **Figure 6: Unc13A and its N-terminus are critical for rapid PHP and AZ-remodeling.**

1143   **(a)** Confocal images of muscle 4 NMJs of abdominal segment 2-5 from 3rd instar larvae at Wild-

1144   type (left) and *unc13A*[Null] (right) NMJs labelled with the indicated antibodies without (control;

1145   black) and with 10 minutes PhTx (+PhTx; blue) treatment. **(b)** Quantification of percentage

1146   change of synaptic BRP, RBP and Cac AZ-levels in Wild-type (blue) and *unc13A*[Null] (red) upon

1147   PhTx-treatment compared to the same measurement in the absence of PhTx for each genotype

1148   (dashed grey line indicates 100%/no change). **(c)** Representative traces of eEPSP (evoked) and

1149   mEPSP (spont.) in Wild-type and *unc13A*^Null animals without (Ctrl; black or grey) and with 10

1150   minutes PhTx (+PhTx; blue or light red) treatment. **(d)** Quantifications of percentage change of

1151   mEPSP amplitude, eEPSP amplitude and quantal content (QC) in PhTx-treated Wild-type (blue)

1152   and *unc13A*^Null (light red) cells compared to the same measurement obtained without PhTx for

1153   each genotype. Traces for (c) were replotted from Fig. 1. **(e)** Left: Full length Unc13A construct

1154   used in rescue experiments of *unc13*^Null animals. Functional domains for AZ localization,

1155   Calmodulin- (CAM), lipid-binding (C1, C2B, C2C) and the MUN domain relevant for SV

1156   release are shown. Right: Schematic of Unc13A construct lacking the N-terminal localization

1157   sequence (C-term-GFP rescue). **(f-i)** Same as in (a-d) for cells re-expressing Unc13A-GFP (blue)

1158   or C-term-GFP (light red) in the *unc13*^Null background. See also Supplementary Figure 8. See

1159   also Supplementary Figure 10 and 11 for non-normalized values. Exact normalized and raw

1160   values, detailed statistics including sample sizes and P values are listed in Supplementary Table

1161   1. Scale bars: (a,f) 5 µm; (c,h) eEPSP: 25 ms, 5 mV; mEPSP: 50 ms, 1 mV. Statistics: Student's

1162   unpaired T-test was used for comparisons in (d), (i) mEPSP change and Mann-Whitney U test

1163   for all other comparisons. *$P \leq 0.05$; **$P \leq 0.01$; ***$P \leq 0.001$; n.s., not significant, $P > 0.05$. All

1164   panels show mean ± s.e.m..

1165   **Figure 7**
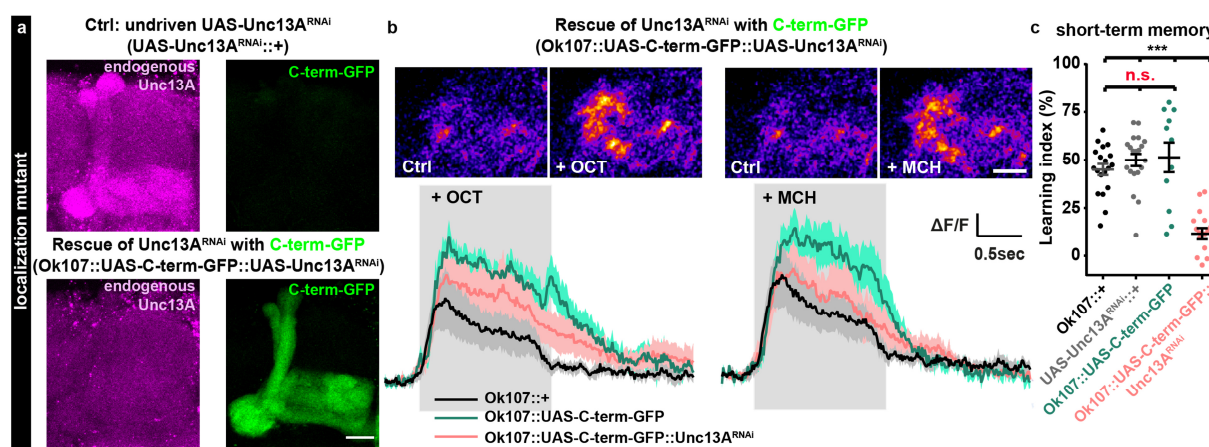

1166

1167   **Figure 7: Mutants incapable of PHP at the NMJ impair short-term memory when**

1168   **expressed in the olfactory learning center of the fly brain.**

1169   **(a)** Confocal images of adult *Drosophila* mushroom-body regions of control (top; undriven

1170   UAS-Unc13A^{RNAi} (UAS-Unc13A^{RNAi}::+)) and rescue of driven UAS-Unc13A^{RNAi} with C-term-

1171   GFP (bottom; Ok107::UAS-C-term-GFP::UAS-Unc13A^{RNAi}) brains labelled with the indicated

1172   antibodies. **(b)** Averaged odor responses measured at the level of presynaptic boutons of M4/6

1173   (MBON-β'2mp/MBON-γ5β'2a/MBON-β2β'2a) mushroom body output neurons (compare[57] or[96]).

1174   Above: sample images of two-photon recordings from M4/6 cells (20 frames averaged

1175   respectively) before and after odor onset. Grey shading indicates the time at which the odor was

1176   applied. Left panels OCT and right MCH response. Below: averaged odor responses. 5 responses

1177   per odor were averaged per animal. Solid lines show mean responses (n = 5 to 6 animals per

1178   genotype). Shaded areas represent the SEM. **(c)** Short-term memory scores after mushroom

1179   body-specific C-term-GFP rescue after Unc13A downregulation via locally driven RNAi

1180   expression (Ok107::UAS-C-term-GFP::Unc13A^{RNAi}) compared to controls expressing the driver,

1181   but not the RNAi (Ok107::+), the RNAi without driver (UAS-Unc13A^{RNAi}::+) or mushroom

1182   body specific overexpression of the C-term-GFP construct (Ok107::UAS-C-term-GFP). See also

56

1183   Supplementary Fig. 9. Exact values, detailed statistics including sample sizes and P values are

1184   listed in Table S1. Scale bars: (a) 20 μm; (b) 10 μm. Statistics: nonparametric one-way analysis

1185   of variance (ANOVA) test, followed by a Tukey's multiple comparison test. ***P ≤ 0.001; n.s.,

1186   not significant, P > 0.05. All panels show mean ± s.e.m.. For representative images experiments

1187   were repeated twice with at least 6-7 brains per genotype.

1188 **Figure 8**
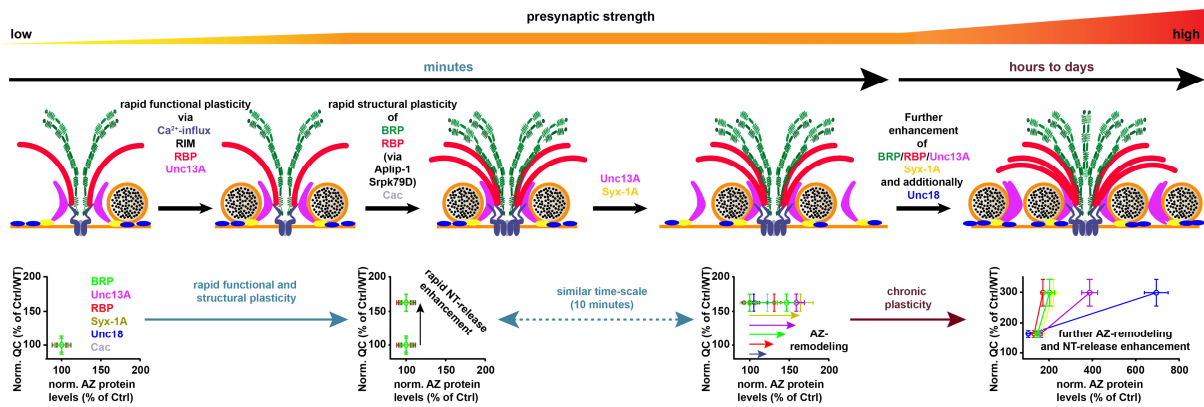

1190 **Figure 8: Sequence of events enabling rapid and sustained homeostatic plasticity**

1191 Top row: Illustration of AZ modes addressed. Bottom row: Plot of normalized quantal content

1192 (QC) vs. AZ protein levels of experiments performed in Fig. 1 normalized to either Ctrl (-PhTx)

1193 for rapid plasticity or Wild-type for chronic plasticity. In the basal activity mode (left), BRP

1194 (green), RBP (red), Syx-1A (yellow), Unc18 (blue) and Unc13A (magenta) provide two SV

1195 release sites at the Ca^{2+}-channel (Cac; light blue). However just one release site is active

1196 (occupied by SV). (Second left) During the rapid functional plasticity phase the quantal content

1197 (and thus neurotransmitter (NT) release) is rapidly enhanced within minutes via mechanisms

1198 involving altered Ca^{2+}-influx as well as RIM, RBP and Unc13A. On a comparable time-scale

1199 (minutes), BRP and RBP are incorporated in a pre-existing AZ in an Aplip-1/Srpk79D dependent

1200 manner and additionally Cac-levels also increase (third cartoon). The BRP/RBP incorporation

1201 enhances AZ levels of Unc13A/Syx-1A providing an additional release sites (fourth left). This

1202 rapid structural AZ-remodeling is not required for the rapid functional plasticity but directly acts

1203 on the consolidation of the release enhancement. (Right) On longer time-scales, chronic

1204 plasticity then further enhances the AZ-levels of BRP, RBP, Syx-1A in a conserved

58

1205   stoichiometry while Unc13A and Unc18 increase out of scale increasing the number of release

1206   sites and thus transmitter release/quantal content activity even further.
