Abstract

Ensuring the safety, health, and overall well-being of animals raised for food is both an ethical obligation and a critical component of providing safe food products. The use of antibiotics for maintaining animal health has come under scrutiny in recent years due to the rise of antibiotic resistance globally. Some U.S. producers, especially in the poultry industry, have responded by eliminating their antibiotic use. The number of animals raised without antibiotics (RWA) is growing in the U.S., but there are concerns that RWA practices might negatively impact animal health and welfare. Therefore, the objective of this survey was to investigate the impacts of RWA production on key parameters such as animal health and welfare, food safety, cost of food production, and consumer demand. Veterinarians, farmers, ranchers, producers, and other stakeholders involved in raising broilers, turkeys, swine, beef cattle or dairy cattle were surveyed. Of the 565 completed responses received, the majority of respondents self-reported as practicing veterinarians or producers. Just over half of respondents reported having past or current experience with RWA programs. The main indicated reasons for raising animals without antibiotics were market driven; switching to RWA production was less commonly made for health-related reasons, such as to reduce antibiotic resistance or to improve animal health and welfare. Although respondents felt that RWA production has negative impacts on animal health and welfare, they overwhelmingly indicated that the customer (retailer/restaurant/food service) believes that animal and health welfare will be significantly improved. Veterinarians and producers indicated that RWA programs will increase production costs with questionable effect on meat, egg or dairy consumer demand. Many respondents felt that there are times when the RWA label takes priority over animal health and welfare. Respondents generally felt that there was a need for increased auditing/assessment of animal health and welfare in RWA systems.

Introduction

Ensuring the health and well-being of animals raised for food is both an ethical obligation and a critical component of providing safe food products. Antibiotics are an important part of animal health programs, but their use has come under scrutiny because of the rise of antibiotic resistance globally (1-4). Efforts have been made to improve antibiotic stewardship in animal agriculture, with different countries often adopting different approaches for enhancing the responsible use of antibiotics (1, 5, 6).

Some animal producers, particularly within the U.S. poultry industry, have eliminated antibiotic use entirely and have adopted a "no antibiotics ever" (NAE) or "raised without antibiotics" (RWA) approach to animal production. In this paper we will refer to these programs as RWA. In RWA programs, antibiotics are only administered for the treatment and control of disease (i.e. there are no production uses nor are antibiotics used for disease prevention). Any animals that have been treated with antibiotics cannot be sold under an RWA label and must be marketed through a different distribution channel. Such circumstances often raise logistical challenges and potential financial losses for the producer.

RWA programs are intended to supply customers, such as restaurants, grocers and other food service establishments, with meat, eggs, and dairy products that can be labeled as having never had exposure to antibiotics. Anecdotal evidence suggests that retail customers and consumers assume that RWA and organic production will improve food safety and decrease antibiotic resistance in animals and humans while providing a more wholesome food product (7). In a recent survey of consumers, 55% responded that they were extremely or very concerned about antibiotic use in chickens when they purchase chicken (8). This same survey found that respondents generally had major misunderstandings about poultry production practices. For

example, 60% of respondents considered themselves to be very or somewhat knowledgeable

about the care of chickens, but 75% believed that there are added hormones or steroids in

chicken meat (which has been illegal in the U.S. for many decades), and 71% believed that

chickens raised for meat are housed in cages (which is untrue). Over half of survey respondents

disagreed with the statement "Eliminating antibiotics leads to significantly more chickens dying

of disease."

Few reports exist comparing RWA to conventionally-reared animals, particularly with

respect to potential impacts on animal health, productivity, and welfare. A report was published

in 2011 by Smith discussing his 12-year experience with RWA in broiler chickens (9), and some

of his experiences included that these birds were more expensive to produce, due in part to

stricter and more expensive diet requirements, and that the drug-free birds had a higher incidence

of important diseases such as necrotic enteritis. More recently, Gaucher et al. (10) reported that

drug-free production was associated with overall negative effects on key performance and gut

health indicators (increased necrotic enteritis incidence, increased feed conversion, decreased

daily weight gain, and decreased mean live slaughter weight), findings which are indicative of

potentially negative impacts on overall animal welfare. These outcomes can contribute to

economic and environmental strain, as RWA programs try to match production output of

conventional programs.

A recent study compared three different broiler production systems: conventional, RWA,

and non-medically important, wherein only antibiotics not considered important to human health

are used (11). The study considered three important health conditions (eye ammonia burns,

footpad lesions, and airsacculitis) which can be indicators of poor animal welfare. Pain from

these conditions can lead to decreased feed intake and reduced weight gain. RWA production

was shown to increase the risk and severity of all three of these health conditions. Use of non-

medically important antibiotics diminished this risk and severity, but the risk was still higher and

disease more severe than that in conventional systems. Study authors emphasized important

limitations to their approach. First, the analyses do not prove a cause and effect relationship; in

other words, the authors are not stating that raising birds RWA causes these conditions to

become worse. Second, they emphasize that they did not analyze management practices and

other related on-farm variables. They state, "Transitioning from medically important antibiotics

to no antibiotics ever generally requires changes be made to production including reduced

stocking density, longer downtime between flock production cycles in a barn, providing an all-

vegetarian feed, etc." Thus many of the negative impacts of RWA production can potentially be

diminished over time, but some might never be completely eliminated. For example, a recent

randomized controlled trial in pigs found that animals reared under RWA conditions had

worsened animal health when there were endemic viral and secondary bacterial infections on-

farm (12).

As more animal production shifts from conventional to RWA programs, there is a need to

understand the impacts of RWA systems on animal health and welfare. The objective of this

study was to survey veterinarians and producers directly involved in animal production about

their experience and perception of the impacts (positive or negative) of RWA animal production

on animal health and welfare. Specifically, this manuscript focuses on the effects of RWA

production in the poultry, beef, swine, and dairy sectors on animal welfare, food safety, and cost

of production. Subsequent reports will describe the survey results regarding the effects of RWA

production on animal health and disease management.

Materials and methods

Survey design

The survey was designed to collect information from veterinarians and producers involved with beef cattle, dairy cattle, swine, turkey, and broiler chicken production. The survey tool was developed by study co-authors and was reviewed by industry experts in each commodity for clarity, completeness, and usability.

Respondents to the survey were only allowed to answer questions for one of the five animal commodities, and this was based on the commodity that the respondent selected at the very beginning of the survey as the commodity with which they were most familiar. The overall survey included questions related to the respondent's RWA program experience, disease and welfare challenges within the respondent's selected commodity, and experiences/beliefs about RWA impacts on animal health and welfare, food safety, cost of production, and antibiotic resistance. The survey was created for online administration using web-based survey software (Qualtrics, Provo, UT, USA) and collected no identifying information from respondents. A complete print-version of the survey is included in S1 Appendix.

Survey dissemination

A hyperlink to the online survey was distributed by various professional organizations and commodity groups such as American Association of Avian Pathologists (AAAP), National Chicken Council (NCC), National Turkey Federation (NTF), U.S. Poultry & Egg Association (USPOULTRY), American Association of Bovine Practitioners (AABP), Academy of Veterinary Consultants (AVC), Animal Agriculture Alliance, National Pork Producers Council (NPPC), National Pork Board (NPB), American Association of Swine Veterinarians (AASV),

133 and Pig Improvement Company (PIC). Announcements were also made at multiple professional

134 and commodity meetings and in key trade journals. The survey was open from February 15 to

135 March 23, 2018.

Data analysis

Incomplete surveys were excluded from analysis. This survey was intended to focus on

animal production within the U.S. Because of the potential for varying regulation, management

practices and production systems to influence responses, data from international respondents

were excluded from analysis. Data analysis was conducted using standard statistical software

(Stata 15.1, College Station, TX, USA). Respondents were categorized as having any experience

with RWA production (RWA respondent) or having no experience with RWA production

(Conventional respondent). Respondent role (e.g., veterinarian, producer) and RWA experience

were compared with two-sample Wilcoxon rank-sum (Mann-Whitney) tests. Likert scale graphs

were prepared in R (13) using packages licorice and ggplot2 (14).

Analyses in this paper focus on study questions related to potential impacts of RWA

production on food safety, animal welfare, cost of production, demand for the respondent's

animal protein or product, and auditing of RWA production systems. Study questions that

focused on impacts on specific animal diseases, animal production, and disease interventions are

addressed in other reports.

Results

Survey responses

153   Five hundred and sixty-five completed responses were received. Ninety-five percent of

154 respondents (n=536) were located within the U.S. (Table 1). Twenty-seven international

respondents were excluded from the analysis and are not included in the results that follow. Most

respondents were practicing veterinarians (n=248, 43.9%), producers (n=214, 37.9%), and

technical services professionals (n=44, 7.8%). Just over half of the respondents were working

with (n=241, 42.7%) or had previously worked with (n=76, 13.5%) animals being raised without

antibiotics (RWA respondents). The remaining respondents (n=248, 43.9%) had no direct

experience with RWA production (Conventional respondents). For the following analyses, only

producers and veterinarians with direct animal responsibilities are included (i.e. technical

services professionals, academics and government employees are excluded). Because only one

turkey respondent had no experience with RWA production, no details of this response are

provided.

Table 1: Characteristics of survey respondents, n=565.

	Total	Broiler	Turkey	Swine	Beef	Dairy
Role	**565**	**69**	**23**	**148**	**244**	**81**
Practicing Veterinarian	43.9%	31.9%	52.2%	37.6%	43.4%	64.2%
Research/Academic/Government Veterinarian	5.1%	1.5%	4.4%	4.7%	4.1%	12.4%
Research/Academic/Government Non-veterinarian	1.1%	2.9%	-	0.7%	1.2%	-
Manager/Producer/Grower/ Rancher/Owner	37.9%	26.1%	26.1%	47.3%	44.3%	14.8%
Technical Services	7.8%	29.0%	13.0%	5.4%	2.9%	7.4%
Other	4.3%	8.7%	4.4%	4.1%	4.1%	1.2%
Country of Experience						
United States	95.2%	86.8%	95.8%	96.0%	97.5%	92.6%
International	4.8%	13.2%	4.2%	4.1%	2.5%	7.4%
Experience with RWA						
Current Experience	42.7%	63.8%	95.7%	33.8%	36.1%	45.7%
Previous Experience	13.5%	2.9%	-	20.3%	13.5%	13.6%
No Experience	43.9%	33.3%	4.4%	46.0%	50.4%	40.7%

Respondents indicated the factors that contributed to their decision to participate in RWA

production (RWA respondents) or reasons why they did not (Conventional respondents), and

these responses are shown in Table 2. RWA respondents in all commodities most commonly

identified market-driven reasons for their decision to participate in RWA production.

Specifically, the most common reason was "to fulfill a client/customer request" (>60% across all

commodities). Conventional respondents most commonly identified "concerns about negative

impacts to animal health and welfare" (>60% across all commodities) and "already raising

animals in a responsible [antibiotic] use program" (>50% across all commodities) as the most

common reasons for not participating in RWA production.

Table 2: Factors contributing to decision to raise animals RWA or Conventionally, n=536.

	Broiler	Turkey	Swine	Beef	Dairy
RWA Respondents	**42**	**22**	**75**	**116**	**44**
To decrease antibiotic resistance	26.2%	9.1%	13.3%	19.8%	2.3%
To improve animal health and welfare	35.7%	13.6%	13.3%	15.5%	9.1%
To increase sale price of animals/product	26.2%	36.4%	54.7%	38.8%	9.1%
To gain market entry into a retail program	31.0%	54.6%	40.0%	27.6%	9.1%
To fulfill a client/customer request	83.3%	81.8%	69.3%	65.5%	77.3%
To eliminate the use of medically important antibiotics	19.1%	4.6%	8.0%	9.5%	4.6%
Conventional Respondents	**17**	**1**	**67**	**121**	**31**
Not profitable	29.4%	-	28.4%	20.7%	6.5%
Concerned about negative impacts to animal health and welfare	94.1%	-	76.1%	65.3%	64.5%
No market pressure	17.7%	-	31.3%	25.6%	19.4%
Not a sustainable consumer trend	41.2%	-	25.4%	12.4%	9.7%
Food safety concerns	17.7%	-	28.4%	8.3%	19.4%
Already raising animals in a responsible use program	58.8%	-	73.1%	56.2%	71.0%

Animal health and welfare

Respondents were asked how they thought RWA production impacts animal health and welfare. Across all five commodities, most RWA and Conventional respondents (> 60% for all commodities) believed that RWA production would slightly worsen or significantly worsen animal health and welfare (Fig 1). Within the broiler, beef, and swine responses, significantly more Conventional respondents believed that RWA production would negatively impact animal welfare than did RWA respondents ($P<0.01$, $P<0.01$, and $P<0.05$, respectively); there was no statistically significant difference between Conventional and RWA dairy respondents. Responses to this question for all respondents (not restricted to practicing veterinarians and producers) are depicted in S1 Fig. Among RWA respondents, producers perceived less of a negative impact on animal health and welfare than did veterinarians. Conventional veterinarian and producer perceptions were more aligned, with both believing that the animal health and welfare impact would be more negative than the beliefs of their RWA counterparts.

Respondents were asked for their perception of customer (retailers, restaurants, or food services) opinions regarding how RWA production impacts animal health and welfare. The perception of the majority of RWA and Conventional respondents (> 60% for all commodities) was that their customers believe that raising animals without antibiotics would slightly improve or significantly improve animal health and welfare (Fig 2). This perception did not differ between RWA and Conventional respondents. Responses to this question for all respondents are depicted in S2 Fig.

Food safety

Across all five commodities, the majority of RWA and Conventional respondents (> 55% for all commodities except RWA beef respondents at 45%) believed that raising animals without

antibiotics would have no impact, slightly worsen or significantly worsen food safety (Fig 3).

Within the broiler and beef responses, significantly more Conventional respondents believed that

RWA production would negatively impact food safety than did RWA respondents (P<0.01 for

broiler and beef). Responses to this question for all respondents are depicted in S3 Fig. When

stratified by role, there was a difference of opinion in the RWA respondent group between

veterinarians and producers, with RWA producers believing that there would be less of a

negative impact on food safety when antibiotics are removed from the production system than

did RWA veterinarians. Within the Conventional group of respondents, veterinarian and

producer perceptions were more aligned regarding the impact of removing antibiotics from the

production system on food safety.

Across all five commodities, the perception among the majority of RWA and

Conventional respondents (> 60% for all commodities) was that their customers (retailers,

restaurants, or food services) believed that raising animals without antibiotics would slightly

improve or significantly improve food safety (Fig 4). There were no statistically significant

differences between RWA and Conventional veterinarians or producers within any of the

commodities; there was a general perception that customers believe that food safety is improved

by RWA production practices. Responses to this question for all respondents are depicted in S4

Fig.

Cost and demand

Across all five commodities, most RWA and Conventional respondents (> 80%) believed

that raising animals without antibiotics would slightly or significantly increase the cost of

production (Fig 5). Among those respondents that work with beef cattle, significantly more

Conventional respondents believed that the cost of production would be increased than did RWA

respondents (P<0.01); there were no statistically significant differences within the other

commodities. Across all five commodities and RWA experiences, veterinarians were more likely

than producers to say that production costs would be increased. Responses to this question for all

respondents are depicted in S5 Fig.

Respondents were also asked how they think RWA production would impact demand for

their protein or product. Across all five commodities, most RWA and Conventional respondents

(> 80%) believed that raising animals without antibiotics would have no impact or would slightly

increase demand for their protein (Fig 6). Significantly more beef, dairy, and broiler RWA

respondents believed that demand would be increased when compared to Conventional

respondents (P<0.05 for each commodity). Across all five commodities and RWA experiences,

producers were more likely than veterinarians to say that the demand for the protein or product

would be increased. Responses to this question for all respondents are depicted in S6 Fig.

Label and auditing

Respondents were asked whether maintaining the RWA label on a product ever takes

priority over flock/herd health and welfare. Specifically, survey participants were asked how

strongly they agree or disagree with the statement: "There are times that maintaining an RWA

label has priority over flock/herd health and welfare." Regardless of commodity type and RWA

experience, responses to this question ranged from Strongly Disagree to Strongly Agree (Fig 7).

A higher percentage of RWA swine and dairy respondents Somewhat Agreed or Strongly

Agreed with this statement than Conventional respondents, whereas the percentages were

approximately equal for the beef and broiler chicken respondents. In general, there were no

major differences between the RWA and Conventional respondents when stratified by role.

Responses to this question for all respondents are depicted in S7 Fig.

Respondents were asked whether more stringent health and welfare auditing and

assessment is needed when raising animals without antibiotics. Across all five commodities and

for both Conventional and RWA respondents, most respondents said that they Somewhat Agree

or Strongly Agree with the need for more auditing and assessment in RWA settings with the

exception of the RWA broiler respondents; only 32% of RWA Broiler respondents said that they

Somewhat or Strongly Agree with this need (Fig 8). When stratified by role, Conventional

veterinarians and producers were more likely to agree with the statement than the RWA

veterinarians and producers. Responses to this question for all respondents are depicted in S8

Fig.

Discussion

This survey was designed to gauge veterinarian and producer experiences and opinions

regarding the impacts of RWA animal production on animal health and welfare. The main

reasons for raising animals without antibiotics were market driven, and in most circumstances,

the decision to switch to RWA production was not made for health-improvement reasons, such

as to reduce antibiotic resistance or to improve animal health and welfare. On the contrary, the

RWA respondents generally tended to indicate that raising animals without antibiotics negatively

affected animal health.

Veterinarians and producers indicated that RWA programs increase production costs but

were less certain that there would be a concomitant increase in consumer demand. Although

respondents largely felt that RWA production negatively impacts animal health and welfare, they

overwhelmingly share the perception that the customer (retailers, restaurants or food services)

believes that animal health and welfare will be significantly improved by raising animals without

antibiotics. Many respondents felt that there are times when maintaining the RWA label takes

priority over animal health and welfare. In general, across all surveyed commodities, respondents

saw a need for increased auditing and assessment of animal health and welfare in RWA systems.

272   Antibiotics remain an important component of health management in animal agriculture.

The decision to use an antibiotic, including the optimization of when, why and for how long to

administer the antibiotic, can be a complex and multi-faceted topic. As is true in the varied

settings and situations of human healthcare, approaches to improving antibiotic stewardship in

animal agriculture, while effectively maintaining animal health and welfare, will differ among

commodity types, animal operations and their veterinarians. A better understanding of the risks

and benefits associated with RWA production is needed, in addition to the documentation of the

changes that have been made in RWA systems to successfully maintain animal health and

welfare. This current study helps fill some of these knowledge gaps and highlights areas where

more information is needed.

282   Given the gaps in our scientific understanding of the impacts of RWA production on

animal health and welfare, as well as the diversity of food labels and marketing messages

encountered in the marketplace, it is no wonder that consumers are confused about antibiotic use

in animal agriculture. The findings from this study indicate that the retailers, restaurants and food

services might also have a skewed perception of the impacts of RWA production. This is

highlighted by the respondents' opinions that their customers believe that RWA production

improves animal health and welfare, in contrast to their own experiences. Studies of food

industry customers are needed to determine the basis for their perceptions of the RWA impact on

animal health and welfare and to better understand the systems used to audit RWA production.

Importantly, a detailed assessment of the auditing that the customers do to ensure that animal

health and welfare are being maintained in RWA systems is critical (15). If audits are conducted

infrequently, on a small number of premises, or rely exclusively on the opinions and reports of

the producers, it is possible, if not likely, that health and welfare problems would be missed.

Clearly there is a need to educate customers and consumers about the role of antibiotics in food

animal production and the challenges of eliminating antibiotics completely from the production

system. Findings from this study can hopefully be used to advance this conversation.

The impacts of raising animals without antibiotics are not restricted to animal health and

welfare. There are also potential effects on environmental sustainability and economic viability.

One recent study developed a simulation model to evaluate the impacts of RWA broiler

production (16). They estimated that if the entire U.S. broiler industry were to shift to RWA

production, impacts would include decreased edible meat, an increase in the number of broilers

needed to meet current demand (680-880 million more birds), associated increases in feed and

water requirements (5.4-7.6 million excess tons and 1.9-3 billion excess gallons, respectively),

and increased manure production (4.6-6.1 million excess tons). The authors conclude that

"eliminating the use of antibiotics in the raising of broilers may have a negative effect on the

conservation of natural resources as well as a negative economic effect via increased prices to

the consumer. Results suggest the need to communicate to consumers the supportive role that

prudent, responsible use of antibiotics for animal disease treatment, control, and prevention plays

in the sustainable production of broilers."

Animal health and welfare, and environmental and economic sustainability, are key

considerations when evaluating RWA production. However, the initial motivation of RWA

production was the goal of reducing antibiotic resistance of human and animal health

importance. Unfortunately, many studies that have attempted to compare Conventional and

RWA production and its impacts on antibiotic resistance have focused on samples obtained from

the retail sector. Retail meat sampling does not allow resistance to be studied at the farm level,

where antibiotics are used and have their effect. Retail meat studies have often provided

conflicting results, with some studies showing more resistance in some bacteria from

Conventional meat production while other studies have found more resistance in RWA meats

(17, 18). Even recent analyses comparing resistant bacteria and resistance gene loads on

Conventional and RWA farms or mathematical modeling studies have found conflicting results

(19-21). There is a need for well-designed, longitudinal studies on farms that can simultaneously

collect data on antibiotic use and resistance so that efforts to improve antibiotic stewardship can

take resistance outcomes into account. Given the potential negative impacts on animal health and

welfare identified in this study, it is important to have an evidence-based understanding of

whether RWA production accomplishes the outcome for which it was intended: reducing

antibiotic resistance on the farm.

328   Conclusions

Based on the responses to this survey, RWA production does not appear to be driven by

prioritization of animal health and welfare. Many respondents felt that there are times when the

RWA label takes priority over animal health and welfare. This observation is deeply concerning,

as protecting animal health and welfare is a key component of the veterinarian's oath (22). If

animals receive antibiotics to treat disease, the meat from these animals cannot be marketed

RWA, and the producers must absorb the added costs associated with RWA production. This

might lead to pressures to sacrifice animal health and welfare to stay in an RWA program. As

stated by Karavolias et al. (2018), "Policies aimed at eliminating or restricting the use of

antibiotics in broiler production may come with potentially negative consequences with respect

to good animal welfare. A more effective policy approach should consider comprehensive

animal care plans that incorporate good housing, management, and responsible antibiotic use,

including the use of ionophores. Policies aimed at informing the consumer on the positive role of

access to antibiotics in supporting good animal welfare while limiting risk of antibiotic resistance

in humans are needed to address the current information gap."

It is well-established that producers who raise animals without antibiotics will sometimes

need to treat the sick animals with an antibiotic, but under these circumstances, the meat cannot

be sold in the RWA packaging even though these animals were raised under the exact same

conditions. This fact is misleading to consumers and strongly supports the need for a different

type of labeling system that is not based on the piece of meat in the package but rather on the

overall system in which the animals are raised. A strictly-audited, systems-based labeling

program would allow consumers to purchase meat and dairy products raised with antibiotics

used responsibly, knowing that animal health and welfare and environmental sustainability have

also been maximized. Producers would then not have to make the decision of maintaining an

RWA label at the expense of animal health and welfare.

Fig 1: Respondents' opinion about impact of RWA production on animal health and welfare.

Five-item Likert scale reporting respondents' opinion, stratified by commodity and RWA

experience.

Fig 2: Respondents' opinion about customer perception regarding the impact of RWA production

on animal health and welfare. Five-item Likert scale reporting respondents' opinion, stratified by

commodity and RWA experience.

Fig 3: Respondents' opinion about the impact of RWA production on food safety. Five-item

Likert scale reporting respondents' opinion, stratified by commodity and RWA experience.

Fig 4: Respondents' opinion about customer perception regarding the impact of RWA production

on food safety. Five-item Likert scale reporting respondents' opinion, stratified by commodity

and RWA experience.

Fig 5: Respondents' opinion about the impact of RWA production on cost of production. Five-

item Likert scale reporting respondents' opinion, stratified by commodity and RWA experience.

Fig 6: Respondents' opinion about the impact of RWA production on demand for their

commodity's protein or product. Five-item Likert scale reporting respondents' opinion, stratified

by commodity and RWA experience.

Fig 7: Respondents' opinion about the statement, "There are times that maintaining a raised

without antibiotics label has priority over flock/herd health and welfare." Five-item Likert scale

reporting respondents' opinion, stratified by commodity and RWA experience.

Fig 8: Respondents' opinion about the need for more stringent health and welfare

auditing/assessment when animals are raised without antibiotics. Five-item Likert scale reporting

respondents' opinion, stratified by commodity and RWA experience.
