1 **Abstract**

2 Madagascar is a biodiversity hotspot that is facing rapid rates of deforestation, habitat
3 destruction and poverty. Urgent action is required to document the status of biodiversity to
4 facilitate efficacious conservation plans. Within country, new generations of Malagasy scientists
5 and conservationists are taking on leadership roles, although many lack access to modern
6 genetic sequencing and are underrepresented in academic publications, when compared to
7 international counterparts.

8 With the recent advent of portable and affordable genetic technologies, it is now possible
9 to tackle logistical considerations. Mobile genetics labs, with the capacity for *in situ* DNA
10 extraction, amplification and sequencing, can produce scientifically reproducible data under field
11 conditions, minimizing the time between sample collection and data analysis. Additionally,
12 mobile labs offer powerful training opportunities for in-country scientists that enable local
13 students and researchers to actively participate and contribute fully to the research enterprise,
14 and that further empower these communities to contribute to the conservation dialog.

15 Here, we show “proof of concept” by deploying a miniaturized thermal cyclor alongside
16 the Oxford Nanopore MinION DNA sequencer in Madagascar, including in the newly
17 established Anjajavy Protected Area in northwestern Madagascar. We successfully extracted
18 DNA from tissue samples collected using minimally-invasive techniques, amplified and
19 sequenced a phylogenetically informative mitochondrial gene (cytochrome-b; *cytb*), and thereby
20 confirmed the presence of Danfoss’ mouse lemur (*M. danfossi*) within the Anjajavy Reserve.

21 To demonstrate the reproducibility of our methods, we successfully performed our
22 established molecular and analytical pipeline at two additional locations in Madagascar, where
23 we also conducted two-day workshops at local higher-education Institutions to demonstrate the
24 process from tissue samples to DNA sequencing. Ultimately, we show that a mobile genetics
25 lab can provide reliable and expeditious results, become a powerful educational tool, and allow

26 scientists to conduct genetic analyses, potentially allowing for rapid interventions under
27 emergency conditions *in situ*.

28

29 **Introduction**

30 Madagascar, one of the world’s most threatened biodiversity hotspots, is fighting severe
31 challenges to the long-term survival of its endemic wildlife due to habitat loss and degradation,
32 while experiencing one of the fastest population growth rates worldwide (Gardner et al. 2018;
33 UNFPA 2018). Thus, there is a sense of urgency to accurately report biodiversity to assess
34 conservation risks and translate these data into policy action. Somewhat paradoxically, thanks
35 to advances in genetic technologies, our quantification of biodiversity levels continues to rise
36 despite high deforestation rates. This is largely the result of new biological surveys targeting
37 poorly known areas, the integration of genetic analyses with more traditional morphological
38 assessments, and a barcoding approach to species identification. Oftentimes, as new species
39 are formally described in the literature, they are immediately tagged as “endangered” or
40 “critically endangered” under International Union for Conservation of Nature (IUCN) regulations,
41 because their distributions are restricted, and their habitats are highly fragmented.

42 This is particularly true of the lemurs of Madagascar, which are currently considered the
43 most threatened group of primates on earth (Estrada et al. 2017). Among them, the “cryptic”
44 nocturnal mouse lemurs (*Microcebus*) have undergone one of the most dramatic taxonomic
45 expansions, with species numbers increasing from only a few to 24 in the last decades (Hotaling
46 et al. 2016). Some mouse lemur species are known to live in sympatry and, in certain cases,
47 there is evidence of hybridization between them, which make species assignment by phenotypic
48 cues challenging at best (Hapke et al. 2011). Further increasing their appeal as research
49 models, genomic data are rapidly accruing, including a genome assembly to chromosome-level
50 for the gray mouse lemur (*Microcebus murinus*) (Larsen et al. 2017).

51 On the flip side of its biodiversity wealth, Madagascar's academic opportunities are rare
52 and limiting. Species descriptions and updates on the conservation status of lemurs have been
53 traditionally led by foreign researchers. Although there is an ongoing trend for Malagasy
54 scientists to take a more active role in project design, data collection and analysis, international
55 collaborations are still vital and encouraged in Madagascar, both to contribute financially and
56 technologically, and to facilitate knowledge production and dissemination. Efforts by Malagasy
57 researchers to encourage these collaborations are especially laudable in the context of national
58 policy and education. Unfortunately, reliance on international support has led foreign
59 researchers to take leadership in publishing and securing funding. This is evident by the
60 underrepresentation of lead-authors affiliated with Malagasy institutions, a trend expected to
61 contribute to weakening high education development and quality for years to come (Waeber et
62 al. 2016).

63 Yet, we are now at scientific, academic, and technological crossroads: A new generation
64 of Malagasy researchers are establishing labs and/or developing research programs in country.
65 At the same time, new DNA sequencing technologies are revolutionizing the fields of genetics
66 and genomics, expanding applications worldwide through the creation of miniaturized devices.
67 These new technological products are relatively affordable and have the potential to sequence
68 even whole genomes in real time (Tyler et al. 2018). At the forefront of these developments are
69 devices released from Oxford Nanopore Technologies (ONT) and miniPCR. These companies
70 have created the MinION (ONT; a portable nanopore-based DNA sequencer platform) and the
71 miniPCR (a miniaturized thermal cycler). These technologies have already been tested under
72 field conditions in a variety of projects around the world, including rapid species assessments in
73 a South American biodiversity hotspot (Pomerantz et al. 2018), disease surveillance to cope
74 with epidemiological crises in West Africa (Quick et al. 2016) characterization of microbiome
75 communities under extreme climatic conditions such as Antarctica (Johnson et al. 2017), and
76 even in outer space (Castro-Wallace et al. 2017). As these technologies are becoming widely

77 available, there is increasing need for operational workflows to simplify analyses and reduce
78 laboratory costs, while being able to survey remote field sites and produce expedited and
79 reliable results (Maestri et al. 2019). And far from least, these technologies are proving to be
80 excellent platforms for engaging in-country students and scientists in the fast-moving area of
81 field genomics (Watsa et al. 2019).

82 Our interdisciplinary research team has been conducting research in Madagascar for
83 decades. Recently, we have furnished a mobile genetics lab for the field, both for research and
84 capacity building. Our objectives were twofold: 1-to test the efficacy of a mobile genetics lab in
85 Madagascar by sequencing a marker gene from mouse lemurs (i.e., genetic "barcoding") and
86 providing the first lemur species assessment *in situ*; 2- to build in-country capacity by
87 conducting workshops at local academic Institutions in Madagascar to gauge the interest and
88 the potential use of the lab as an educational tool for high education students.

89 **Methods**

90 *Lab implementation in Madagascar*

91 Our mobile genetics lab included equipment, reagents and supplies needed to process
92 samples from DNA extraction to sequencing (Table 1). We tested all lab components at Duke
93 University, North Carolina, USA. The lab was fitted in two Pelican cases and shipped from the
94 USA to Madagascar in May 2018 (Sup. Inf.). In Sambava, NE Madagascar, we conducted our
95 first lab test in country, checking reagents and flow cells, testing equipment and troubleshooting
96 lab protocols to local conditions. This comprehensive testing included DNA extractions, PCRs,
97 library preparations and sequencing, using tissue samples stored at the office from previous
98 research missions. Moreover, MBB and LKG trained LA in the basics of lab operation. Then, the
99 three of us organized a two-day workshop conducted at the Centre Universitaire Régional de la
100 SAVA (CURSA) a local branch of the University of Antsiranana in northeastern Madagascar.

101 In early July, MBB and LKG moved the lab from Sambava to a field site, the Anjajavy
102 Lodge and Reserve. This site was ideal because it has electricity, an unusually high density of

103 mouse lemurs and, importantly, because the species of mouse lemur at this site has/have yet to
104 be genetically confirmed. Anjajavy (S14.99025 E47.22958) encompasses ~1,200 ha of private
105 Reserve, and ~8,000 ha of recently protected area, predominantly dry deciduous forest. We
106 conducted our field mission between July 9 and 29, 2018. During the first 10 days of our
107 mission, we captured and obtained tissue samples from 12 mouse lemurs. During the last 10
108 days in the field, we extracted all tissue samples and chose a high-quality extraction to
109 sequence. The process from DNA extraction until sequencing took ~ 8 hours and was
110 partitioned over two days (Sup. Inf.).

111 After Anjajavy, we traveled to the capital Antananarivo to set the lab at the Vahatra
112 Association office, the leading Malagasy NGO promoting capacity building and scientific
113 research in Madagascar. With logistical assistance from Vahatra staff, we conducted our
114 second workshop at the Vahatra Association's office, for university students and researchers
115 interested in genetics.

116 *Sample processing and analysis*

117 Genomic DNA was extracted from tissue samples using DNeasy Blood & Tissue Kit
118 (Qiagen, Hilden, Germany) according to the manufacturer's protocol. We incorporated
119 mechanical lysis (i.e., bead beating) as an additional step after chemical lysis. We selected to
120 sequence the entirety of the mitochondrial gene, *cytb*, (~1100bp) which has proven a reliable
121 phylogenetic marker for mouse lemurs (Hotaling et al. 2016). We amplified *cytb* using the
122 miniPCR thermal cycler. We used a PCR cleanup protocol with AMPure beads before
123 proceeding to sequencing. DNA library preparation and flow cell loading were carried out
124 according to the protocols by ONT. Flow cell pore availability ranged between 85 and >1000
125 active pores (Sup. Inf.).

126 We allowed each library to run for 1 hour, and we used MinKNOW software to base call
127 for 3-8% of bases. This low percentage was enough to accomplish great depth in sequencing
128 coverage with more than 10,000X of the *cytb* amplicon per sample. Sequenced data were

129 stored as FASTq files and retrieved using MinKNOW software. Raw reads were first filtered by
130 read length between 1000 and 1400 bases (approximating that of the *cytb* gene) and then
131 mapped to a *M. murinus cytb* reference sequence (GenBank accession number: U53572)
132 before generating a consensus sequence. Consensus sequences were aligned to the reference
133 sequence using Geneious software, and then blasted to our database comprising ~ 270
134 published (NCBI GenBank) and unpublished mouse lemur sequences from the Yoder lab.
135 Finally, we created a phylogenetic tree using Neighbor-Joining (NJ) analysis with uncorrected p-
136 distances as implemented in PAUP version 4a165. One thousand bootstrap trees were also
137 estimated by NJ with PAUP and we used RAxML version 8.2.12 to draw bootstrap support onto
138 the nodes from the original data set. The phylogenetic tree was edited in FigTree version 1.4.4.

139 All research protocols complied with Institutional Animal Care and Use of Animals at
140 Duke University (IACUC# A263-17-12), and field research was approved by the Ministry of
141 Environment, Ecology and Forests of Madagascar (Permit#
142 035/18/MEEF/SG/DGF/DSAP/SCB.Re).

143

144 **Results**

145 In total, we sequenced DNA from four mouse lemurs using the mobile genetics lab in
146 Madagascar. Two mouse lemur samples were sequenced in Sambava, one sample was
147 sequenced *in situ* at the Anjajavy field site, and one sample was sequenced in Antananarivo
148 (Fig. 1). All mouse lemur samples grouped with those of *Microcebus danfossi*, thus we
149 genetically confirmed the presence of this species at Anjajavy (Fig. 2). Consensus sequences
150 generated in this study were stored in GenBank under accession numbers XXX-XXX.

151

Fig.1 Locations for the use of the genetics lab. 1.Sambava: (a) Loading gel in the DLC/SAVA office, (b) Loading MinION prior to sequencing; 2. Anjajavy: (a) deciduous forest, (b) lab setting near forest, (c) Danfoss' mouse lemur; 3. Antananarivo: lab setting at Vahatra office.

152

153 We conducted two workshops to target college students, at the Centre Universitaire
154 Régional de la SAVA (CURSA) in the town of Antalaha, and at the Vahatra Association office, in
155 the capital Antananarivo (Fig. 3). During both workshops, we described and demonstrated all
156 procedures from tissue extraction to sequencing to species assignment. A total of 66 students
157 attended the workshop at CURSA conducted in Malagasy, where some students actively
158 participated in hands-on molecular techniques such as pipetting, loading samples in the
159 miniPCR thermal cycler, setting the agarose gel and loading samples using the Bluegel DNA

160 electrophoresis kit. At Vahatra Association, a total of 25 students (the maximum room capacity)
161 attended the workshop, which was conducted in English. These participants had more
162 comprehensive backgrounds in genetics, so workshop participants engaged in all lab activities
163 as well as discussions about potential implementation of this technology in a variety of research
164 topics. During the workshop at Vahatra Association, we sequenced a mouse lemur sample from
165 our recent field mission at Anjajavy.

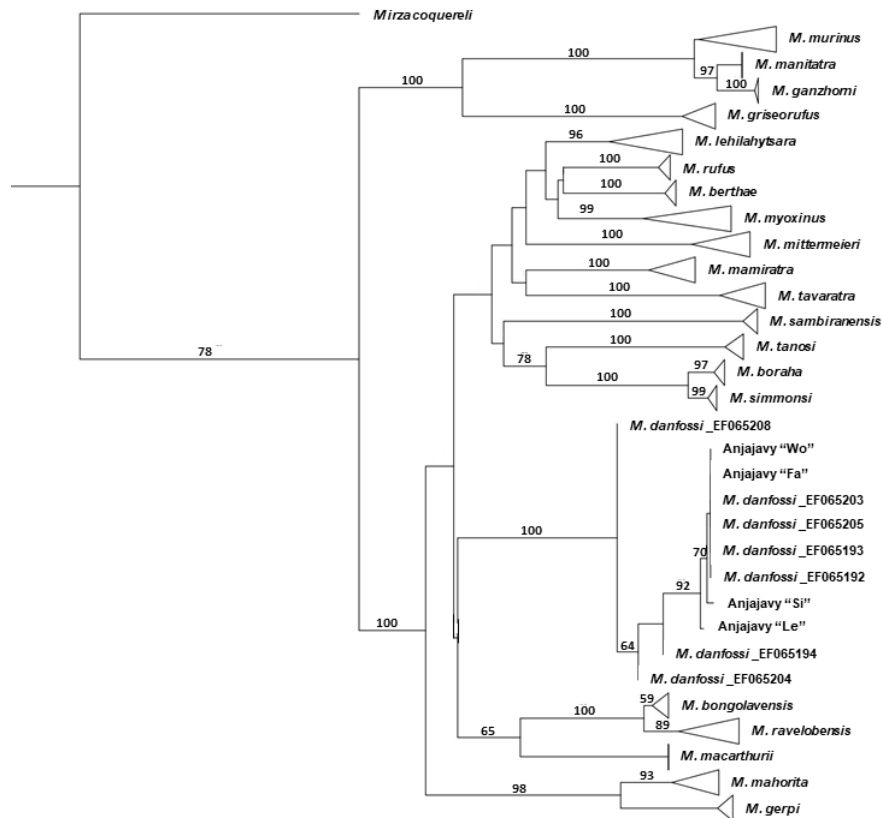

Fig. 2 *Microcebus* phylogeny based on *cytb* sequences. Branches were collapsed for practical purposes, except for the *M. danfossi* lineage, to highlight consensus sequences from Anjajavy; node support above 50 % is shown. GenBank accession numbers for Anjajavy samples are pending, those for published sequences of Danfoss' mouse lemurs are listed next to the species name.

167

168 Discussion

169 Portable and affordable technologies in the field of genetics have made it feasible to
170 produce scientifically robust data under field conditions, minimizing the time between sample
171 collection and data analysis. The capacity for *in situ* genetics also provides training opportunities
172 to enable active participation of local students in the whole process of scientific research.

173 To our knowledge, we were the first researchers to perform *in situ* sequencing of wild
174 lemurs in Madagascar. We were able to confirm species assignment for one of the lemurs at
175 Anajavy within a week, from lemur capture to tissue collection, to the generation of a
176 phylogenetic tree. Our results are consistent with the known distribution of *M. danfossi*, between
177 the Sofia and Maevarano rivers, NW Madagascar (Olivieri et al. 2007). Anajavy's mouse lemurs
178 had been tentatively assigned as *M. danfossi* on the basis of morphological assessments

179 (Randrianambinina et al. 2010), but we provide the first genetic confirmation of Danfoss' mouse
180 lemurs at this site.

181 We would like to emphasize that mobile genetics technology not only minimizes time
182 between sample collection and analysis, but has the potential to address urgent conservation
183 concerns in *real time*. Conservation crises can span from needing rapid biodiversity
184 assessments in threatened habitats, to dealing with wildlife die-off situations or disease-related
185 cases that require immediate intervention (e.g., Carver 2018).

186 We showed “proof of concept” that this technology can be deployed in remote sites, that
187 results can be obtained in a speedy manner and that training sessions can prepare advanced
188 students with the skills and means to conduct genetic analysis *in situ*. As a testament to the
189 latter point, both MBB and LKG who deployed the lab in Madagascar, had some experience
190 with molecular genetics and analysis, but are not geneticists themselves. Week-long training in
191 the USA provided the necessary skills, tools and information to run the lab on the ground in
192 Madagascar and train LA and others in its use.

193 One unexpected corollary of the workshops was the general interest from participants to
194 apply these technologies to a large range of research topics. We also learned that there are
195 facilities and Institutions in country already using MinION technology such the Mahaliana Lab
196 (<https://www.mahaliana.org/>) and the Pasteur Institute (<http://www.pasteur.mg/>). Connectivity
197 among the scientific community, both national and international, will be beneficial for
198 researchers interested in funding, contracting services or collaborating with them. Finally, we
199 showed that the mobile genetics lab can be a powerful educational tool, for teaching basic
200 concepts to introductory students, or exemplifying complex procedures for advanced college
201 students with background in biological sciences. Thus, the potential for this technology to
202 immediately produce data, coupled with the power of capacity building to engage local
203 researchers significantly outweighs the logistical challenges to obtain, transport and maintain
204 lab supplies and reagents in remote settings.

205 In sum, miniaturized and more affordable technologies have the potential not only to
206 speed up production of knowledge and solve biological and environmental crises in efficacious
207 manners at remote settings, but also to shape the professional careers of passionate scientists
208 in less advantageous academic settings and to level the scientific playing field.

209

210 **Acknowledgements**

211 We thank the Malagasy Government for authorizing us to conduct research in
212 Madagascar. We thank A. Raselimanana for his help advertising the workshop at Vahatra office,
213 Antananarivo. We also thank S. Goodman for allowing us to use the Vahatra office for the
214 workshop. Equipment and supplies for the mobile lab were made possible by a private donation
215 to PAL and the Duke Lemur Center from W. Korman and Google Inc. Funding for this project
216 was provided by Global Wildlife Conservation's Lemur Conservation Action Fund and IUCN
217 SOS. Funding for LKG was provided by an NSF DDRIG BCS 1749898. Additional travel and
218 supplies were supported by funds from the John Simon Guggenheim Foundation to ADY. We
219 thank S. Bornbusch, R. Schopler and K. Thompson for acquiring and transporting supplies to
220 Madagascar. We are also grateful to C. de Foucault, E. Rabeloson, H. Rasoanaivo and
221 Anjavy staff members for their assistance in the field. We are grateful to G. Tiley for his
222 assistance with the phylogenetic analysis. This is a DLC publication # XXX.

Travel itinerary

Our genetics lab was shipped in two Pelican cases from Washington Dulles Airport, USA to Ivato Airport Antananarivo, Madagascar in early May. The trip included two flights and was ~ 27 hours total. The following morning, the lab was shipped to the town of Sambava (NE Madagascar) via air freight, and less than 24 hours later, it was brought by car to the Duke Lemur Center/SAVA Conservation office for storage with an available fridge/freezer unit. In between international and domestic flights, sensitive reagents and flow cells were kept in coolers and refrigerated with ice packs. In early July, the lab was shipped back from Sambava to Antananarivo via air freight and, less than 48 hours later, we rented a car and drove to the town of Mahajanga, (NW Madagascar) for 13 hours. Less than 24 hours later, we rode a boat from Mahajanga to the field site, the Anjajavy Lodge and Reserve, a trip that lasted 4.5 hours. In between transportation routes, we placed reagents and flow cells under refrigeration and replaced ice packs. In late July, we reverted the original route, taking the genetics lab from Anjajavy back to Antananarivo.

Lab protocols

Primers and PCR: Primers to amplify *cytb* gene were L14724: 5'-CGA AGC TTG ATA TGA AAA ACC ATC GTT G-3', and H15915: 5'-AAC TGC AGT CAT CTC CGG TTT ACA AGA C-3' as previously described in Irwin et al. (1991). Each Polymerase chain reaction (PCR) contained approximately 1.5 μ L of PCR product, 12.5 μ L LongAmp Taq DNA Polymerase (New England Bio Labs), 1.25 μ L of each primer, and 8.5 μ L water for a 25 μ L total volume. Samples for the PCR run followed the following settings: initial denaturation 95°C for 2 minutes, 32 cycles of denaturation at 95°C for 30 seconds, annealing at 57°C for 30 seconds, extension at 72°C for 45 seconds, and a final extension at 72°C for 480 seconds. PCR products were then cleanup using AMPure beads and washed in 70% EtOH before resuspending in water.

Library preparation: DNA products (45 μ L amplicon) were prepared with 7 μ L Ultra II End-prep reaction buffer and 3 μ L Ultra II End-prep enzyme and 5 μ L water. Samples were washed using AMPure beads and 70% EtOH and resuspended in 30 μ L water. Adapter ligation and tethering was then carried out with 20 μ L of Adapter Mix (ONT) and 50 μ L of NEB Blunt/TA ligation Master Mix (New England Biolabs). The adapter ligated DNA library was then purified with AMPure beads and ABB buffer. Samples were resuspended in 13 μ L water and placed in a LoBind tube ready for sequencing.

Sequencing: We prepared pre sequence-library following ONT protocols, by mixing 12 μ L amplicon, 2.5 μ L water, 25.5 μ L LBB and 35 μ L RBF. We inserted flow cell in the MinION frame, and loaded the flow cell's priming port with 800 μ L of priming mix (576 μ L RBF and 624 μ L water) with SpotON cover closed. We additionally loaded 200 μ L priming mix in priming port with SpotON cover open. The sample was then added to SpotOn por via dropwise fashion. Finally, we covered SpotOn and priming ports, close the MinION lid and open the MinKNOW GUI software to proceed to sequence. Note: We were authorized by ONT to use MinKNOW 18.5.1.0 version to base call offline, because we were off grid at Anjajavy.

Flow cells: We used a total of three flow cells (R 9.4), one at each location: Sambava, Anjajavy and Antananarivo respectively. Flow cell number one, used in Sambava, was transferred with the mobile genetics lab in May, and contained more than 1000 active pores at the time of use, well over the 800 threshold recommended by company. Flow cell number two was brought by a researcher to Anjajavy in July, and contained 85 active pores. Despite the low count, likely the result of disrupted transportation conditions, results obtained from this unit were reliable. In fact, our ability to reliably sequence *cytb* gene speaks to the great redundancy buffer provided by flow cells, when relatively short and single genes are the source of sequencing. Flow cell

number three was brought by another researcher in September to Antananarivo, and used for our last sequencing event. This flow cell contained over 1000 active pores at the time of sequencing.

Note: When we tested the lab at Duke University, we sequenced a sample from a grey mouse lemur (*M. murinus*) from the Duke Lemur Center using the MinION sequencer, and generated a consensus sequence that was 100% identical to the reference sequence that had been generated by Sanger sequencing.

Sampling methods

Mouse lemurs were captured with Sherman traps (3 x 3.5 x 9") baited with small pieces of banana and set along trails at 1.5m height. Traps were set in the afternoon and checked in the mornings for 6 days. All captured lemurs were brought back to the campsite for processing. At the campsite, individuals were weighed, measured, and microchipped for identification (Trovan®). Tissue samples (ear biopsies, 2mm) were taken from anesthetized individuals (Ketamine, 10mg/kg) and stored in 90% alcohol for further analysis. Individuals were released at trapping sites later the same day.
