19 **Abstract**
20 Bio-fluids contain various circulating cell-free RNA transcripts (ccfRNAs). The composition of
21 these ccfRNAs varies between bio-fluids and constitute tantalizing biomarker candidates for
22 several pathologies. ccfRNAs have also been demonstrated as mediators of cellular
23 communication, yet little is known about their function in physiological and developmental
24 settings and most works are limited to in-vitro studies. Here, we have developed iTAG-RNA, a
25 novel method for the unbiased tagging of RNA transcripts in mice in-vivo. We used this method
26 to isolate hepatocytes and kidney proximal epithelial cells-specific transcriptional response to a
27 dietary challenge without interfering with the tissue architecture, and to identify multiple
28 hepatocyte-secreted ccfRNAs in plasma. We also identified transfer of these hepatic derived
29 ccfRNAs to adipose tissue, where they likely serve as a buffering mechanism to maintain
30 cholesterol and lipid homeostasis. Our findings directly demonstrate in-vivo transfer of RNAs
31 between tissues and highlight its implications for endocrine signaling and homeostasis.

Darr J. et. al.

32

Introduction

34   Little is known about the biological function of circulating cell-free RNAs (**ccfRNA**). Found to be

35   associated with exosomes, lipoproteins, ribonucleoproteins and more, these transcripts can be

36   isolated and sequenced from multiple bio-fluids such as plasma, lymph, cerebral fluids, breast milk

37   and more [1, 2]. ccfRNAs are directly implicated in the development of several pathologies

38   including cancer and obesity [3-5] and are intensively studied as disease biomarkers [6, 7]. Despite

39   this, the role they play in physiological and developmental settings and in mediating cell-to-cell

40   communication remains largely unknown. In-vitro, a growing number of works demonstrate the

41   relevance of RNA based cellular communication [8-11], however in-vivo evidence is still limited.

42   This discrepancy is partly due to the difficulties posed to tracking ccfRNAs from transcriptional

43   source to potential sites of action in-vivo. Indeed the tools available to study ccfRNAs in

44   physiological settings are limited and very few studies attempt to tackle this problem directly.

45   One work found evidence to suggest that the majority of circulating miRNAs originate in adipose

46   tissue and that some of the adipose derived miRNAs may play a role in the regulation of liver

47   Fgf21 levels [12]. However, this work focuses on miRNA and does not directly demonstrate

48   transfer of RNAs between tissues nor directly identify adipose secreted RNAs.

49   Transfer of miRNAs was also demonstrated between epithelial cells of the caput epididymis to

50   maturing spermatozoa, leading to a shift in sperm RNA content during its maturation [13]. This

51   study made use of 4-thiouracil-tagging (TU-tagging) [14] combined with SLAM-Seq [15] to

52   demonstrate loading of miRNAs transcribed in caput epididymis into maturing spermatozoa. TU-

53   tagging entails cell-type specific expression of uracil phosphoribosyltransferase (UPRT) and

54   administration of 4-thiouracil, with the assumption that only cells expressing UPRT would

55   incorporate 4-thiouracil into transcribing RNA. Thio-RNA can then be purified and used for

56   downstream gene expression analyses, or alternatively combined with SLAM-Seq to identify

57   labeled transcripts. TU-tagging has proven useful in several additional systems [14, 16, 17],

58   however, given endogenous [18] and alternative [19] pathways for uracil incorporation, the

59   labeling specificity in this method remains unclear. In addition, as is demonstrated in Herzog et.

60   al [15] and by Sharma et. al [13], labeling with TU-tagging of PolI and PolIII transcripts is

61   inefficient, rendering tRNAs and ribosomal transcripts unlabeled.

Darr J. et. al.

62 Indeed there are only a limited number of techniques enabling in-vivo targeted labeling of RNAs.

63 In addition to TU-tagging, 5-ethynylcytosine-tagging (EC-tagging) [20] is a new method, which

64 utilizes cell-type specific co-expression of cytosine deaminase (CD) with UPRT to achieve RNA

65 labeling with 5-ethynyluridine (5EU) following administration of 5-ethynylcytosine. Both TU and

66 EC tagging use cre-recombination to express the relevant enzymes in a tissue specific manner and

67 stochastic expression from the cre-promoter may lead to unwanted expression of the enzymes in

68 different tissues [21]. Finally, one recently developed method called Mime-seq allows for cell type

69 specific labeling of microRNA [22]. In this method, tissue specific expression of a plant derived

70 methyltransferase mediates a 3′-terminal 2′-O-methylation of microRNAs that, when combined

71 with a methylation dependent library construction, allows for sequencing of tissue specific

72 microRNAs. Mime-seq allows labeling of miRNAs alone leaving other RNA biotypes unlabeled.

73 Given the need for a technique that allows for a Cre-independent and unbiased labeling of total

74 RNA transcription in-vivo, we developed iTAG-RNA **[For In-vivo Targeted Tagging of RNA]**.

75 This method incorporates mouse genetics with a novel uridine analog and an established RNA

76 labeling chemistry to allow tagging of total RNA in target cells in-vivo. Using iTAG-RNA we are

77 able to identify transcriptional re-programming of hepatocytes in-vivo following an acute high fat

78 diet stress and to enrich for and identify hepatocyte derived plasma ccfRNAs. Moreover, we are

79 able to identify RNA-based liver-to-adipose RNA transfer. These liver derived ccfRNAs include

80 variable coding and non-coding RNAs such as miRNAs and tRNAs. Among the miRNAs

81 transferred from liver to adipose tissue we find mir-33, mir-10b and mir130a, which target major

82 regulators of cholesterol and lipid efflux and bio-synthesis such as Srebf1 [23], Abca1 [23, 24],

83 Ppara [25] and Pparg [26] respectively.

84 Our study demonstrates for the first time an unbiased technique that allows labelling, tracking and

85 quantification of variable types of ccfRNAs from their transcriptional source to downstream

86 tissues, in which they can potentially act to regulate expression of target genes. We demonstrate

87 RNA-based liver-to-adipose transfer of a myriad of RNA transcripts and their response to an

88 environmental challenge. The continued identification and characterization of RNA based

89 signaling in-vivo is imperative for the understanding of developmental, physiological and

90 pathological processes, and can aid in the future development of relevant disease biomarkers.

91

92 **Results**

Small molecule design and genetic approach for targeted in-vivo labeling of RNA

5-Ethynyl Uridine **(5EU)** is a synthetic uridine analogue extensively used in RNA turnover studies [27-29]. The nitrogenous base contains an alkyne group that can be covalently linked to an azide group using a simple copper mediated reaction called click chemistry [30, 31]. This synthetic base has been demonstrated to incorporate into transcribing RNA in place of uridine and have little to no biological effects thereafter [27]. Following administration to mice, 5EU is readily taken up by cells with no regard to cell identity, depending to some extent on the administration method and dosage used [27]. Here, we present a novel method for the targeted in-vivo delivery of 5EU.

To achieve this, we designed a 'pro-drug' of the 5EU base **(HD5EU)** that is based on the 'Hep-Direct' pro-drug design [32, 33] **(Figure 1a)**. This design was developed to target small molecules and nucleotide analogues to the human CYP3A4 enzyme and several small molecules of this design have been or are currently in clinical studies [34-36]. The human CYP3A4 enzyme catalyzes an oxidative cleavage of the HD5EU small molecule which, following a spontaneous beta-elimination, results in the formation of 5EU mono-phosphate that can then be incorporated into transcribing RNA **(Figure 1a)**. HD5EU was synthesized by Chiroblock GmbH, the identity of the final product was validated using MS, p-NMR and h-NMR and the molecule's purity was assessed at over 98% **(Sup. Figure 1a-d)**.

In addition to the HD5EU small molecule we took advantage of the published humanized liver specific CYP3A4 mouse line **FVB/129P2-*Cyp3a13*[tm1Ahs] Del(*5Cyp3a57-Cyp3a59*)[1Ahs] Tg(*APOE*-CYP3A4)[A1Ahs]** obtained from Taconic [37, 38]. These humanized mice **(hCYP3A4)** express the human CYP3A4 enzyme under a modified Apolipoprotein E (APOE) promoter and are stably knocked out for nine homologous murine genes, thus leaving the human enzyme as the sole member of the enzyme family to be expressed in a Cre-independent, tissue-specific manner in-vivo. In keeping with published data on the activity of the modified ApoE promoter [39], qRT-PCR and WB analyses demonstrate restricted expression of the human Cyp3a4 enzyme to liver and kidney (**Figure 1b-c**). As such, upon administration of the HD5EU small molecule to the humanized CYP3A4 mice, we expect the molecule to be metabolized to bioavailable 5EU mono-phosphate exclusively in cells expressing CYP3A4, namely hepatocytes and kidney proximal renal epithelial cells**,** thus allowing in-vivo targeted labelling of transcription and identification of secreted transcripts in bio-fluids upon pull-down of 5EU labelled RNA (**Figure 1d**).
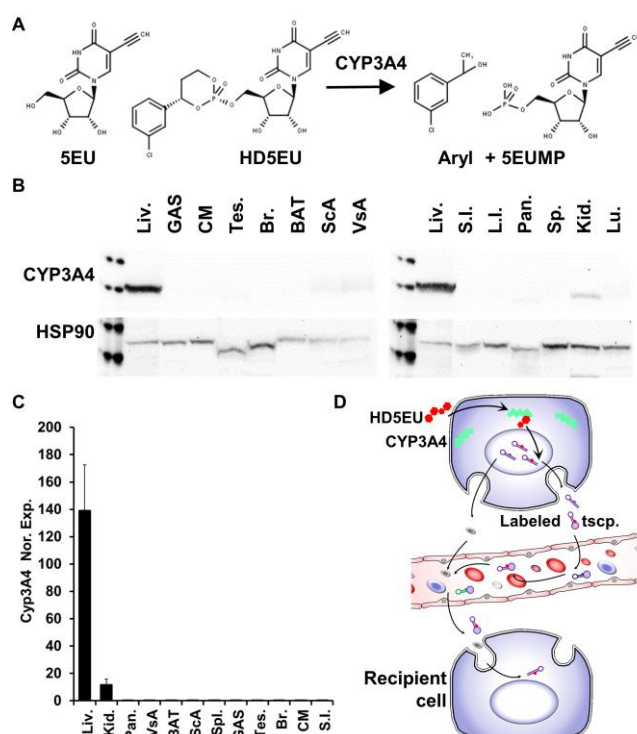

4

A) HD5EU small molecule and metabolite structure relative to 5EU. **B)** W.B. depicting tissue expression pattern of CYP3A4 in humanize CYP3A4 cluster deleted mice. HSP90 serves as loading control. GAS = Gastrocnemius muscle; CM = Cardiac Muscle; BAT = Brown adipose tissue; ScA = Subcutaneous white adipose tissue; VsA = Visceral white adipose tissue; S.I. = Small intestine; L.I. = Large intestine. **C)** qRT-PCR validating liver and kidney specific expression of CYP3A4. Error-bars for standard-deviation of 3 biological repeats. **D)** Administration of the HD5EU small molecule to cells expressing CYP3A4 allows metabolism to 5EU and labelling of total RNA. Labeled transcripts are then secreted to the extracellular matrix and can be identified in bio-fluids and recipient cells.

CYP3A4 is necessary for in-vitro and in-vivo metabolism of the HD5EU small molecule

To test and validate the metabolism of the HD5EU small molecule, we first isolated primary hepatocytes from hCYP3A4 mice. Following an 8 hour treatment of primary hepatocytes with 1mM HD5EU or 5EU, nuclear staining similar to 5EU labeling is clearly evident following click-it fluorescent staining **(Figure 2a)**. When pre-treated with Azamulin, a highly selective CYP3A4 inhibitor [40], HD5EU treated primary hepatocytes no longer demonstrate nuclear staining, in contrast to 5EU treated primary hepatocytes, where nuclear staining is unaffected by Azamulin pretreatment **(Figure 2a)**. These results indicate that while 5EU is still readily incorporated into transcribing RNA in the nucleus, nuclear staining in HD5EU treated cells is dependent upon CYP3A4 activity.

We administered HD5EU to humanized CYP3A4 mice and already 2 hours following administration found robust nuclear staining in hepatocytes and kidney epithelial cells but in no

5

Darr J. et. al.

155 other tissue examined. This in contrast to mice administered with 5EU where nuclear staining was

156 evident in multiple tissues **(Figure 2b-c and sup. Figure 2a).** Of note, animals administered with

157 HD5EU did not demonstrate any visible side effects. In addition we could not detect any signs of

158 DNA damage or apoptosis in the liver during the different treatment regimens as demonstrated by

159 staining for phosph-P53 and cleaved Caspase-3, supporting HD5EU as a non-toxic agent **(Sup**

160 **Figure 2b)**.

161

162

163 **Figure 2. Tissue specific staining evident with HD5EU is dependent on CYP3A4 activity.**

164 **A)** Primary hepatocytes demonstrate fluorescent nuclear staining of nascent RNA transcription

165 following 8 hours of 5EU and HD5EU treatment. Azamulin treatment hinders fluorescent nuclear

166 staining in HD5EU treated cells but not 5EU treated cells. 594-azide used for click-it staining. **B)**

167 Following 2 hours of HD5EU administration to mice, in-vivo fluorescent nuclear staining is

168 restricted to hepatocytes and epithelial cells in the kidney and absent from other tissue as evident

169 in panel C and supplementary figure 2. Sol. = solvent for HD5EU. **C)** A similar treatment with

170 5EU in-vivo results in fluorescent nuclear staining of cells in multiple tissue including; Spleen,

171 Pancreas, Muscle, Small Intestine, Brain and VsWAT. Consecutive injections did not change the

172 observed staining pattern as no tissue apart from liver and kidney demonstrated positive staining.

173 Scale Bar = 50µM. For negative controls see supplementary figure 2.

6

174

Mass-Spectrometric validation and quantification of 5EU incorporation into RNA following HD5EU treatment

To validate that nuclear staining evident in-vitro and in-vivo following HD5EU treatment is indeed indicative of 5EU incorporation into transcribing RNA, we adopted the mass-spectrometry method described by **Su et. al [41]**. Using a column with a smaller inner diameter and lower flow rates to improve the response of individual nucleotides, we were able to identify a wide range of unmodified and modified nucleotides **(Sup. Table 1)**. 5EU (m/z 269.0768) was well separated from the potential interfering 13C-Adenosine isotope (Adenosine m/z 268.1040, 13C-Adenosine m/z 269.106541) in standard samples **(Figure 3a)**. Due to mass spectrometric settings all nucleotides show a prominent in-source fragment, which corresponds to the neutral loss of the ribose **(Figure 3b**, denoted as $[M-132+H]^+$).

Tandem mass spectrometry validated that 5EU is present in RNA extracted from the liver of HD5EU treated mice **(Figure 3a-d)**. The main fragment at 20eV collision energy was the neutral loss of ribose ($[M-132+H]^+$) consistent with the observed in-source fragment **(Figure 3b-c)**. Further fragments of the remaining nucleoside fragment were observed under higher collision energy of 40 eV **(Figure 3d)**. To quantify 5EU incorporation into RNA we used the prominent in-source fragment of 5EU due to the low abundance of 5EU in biological samples, as this in-source fragment was up to 3-5-fold higher than the intact molecule. In-vitro, Azamulin treatment of primary hepatocytes inhibited HD5EU metabolism and incorporation into transcribing RNA **(Figure 3e)**, in-line with observed fluorescent staining **(Figure 2a)**. In-vivo, we could detect and quantify 5EU incorporation into both short (less than 200bp) and long RNA isolated from the liver of HD5EU treated mice, 2 hours following the administration of the compound **(Figure 3f-g)**. 8h following HD5EU administration 5EU was still detectable in long RNA (though it could not be accurately quantified as it was below quantification limit), whilst only a moderate reduction was detected in short RNA.

Taken together, these results confirm that HD5EU is metabolized in a CYP3A4 dependent manner to 5EU, which is then incorporated into transcribing RNA.
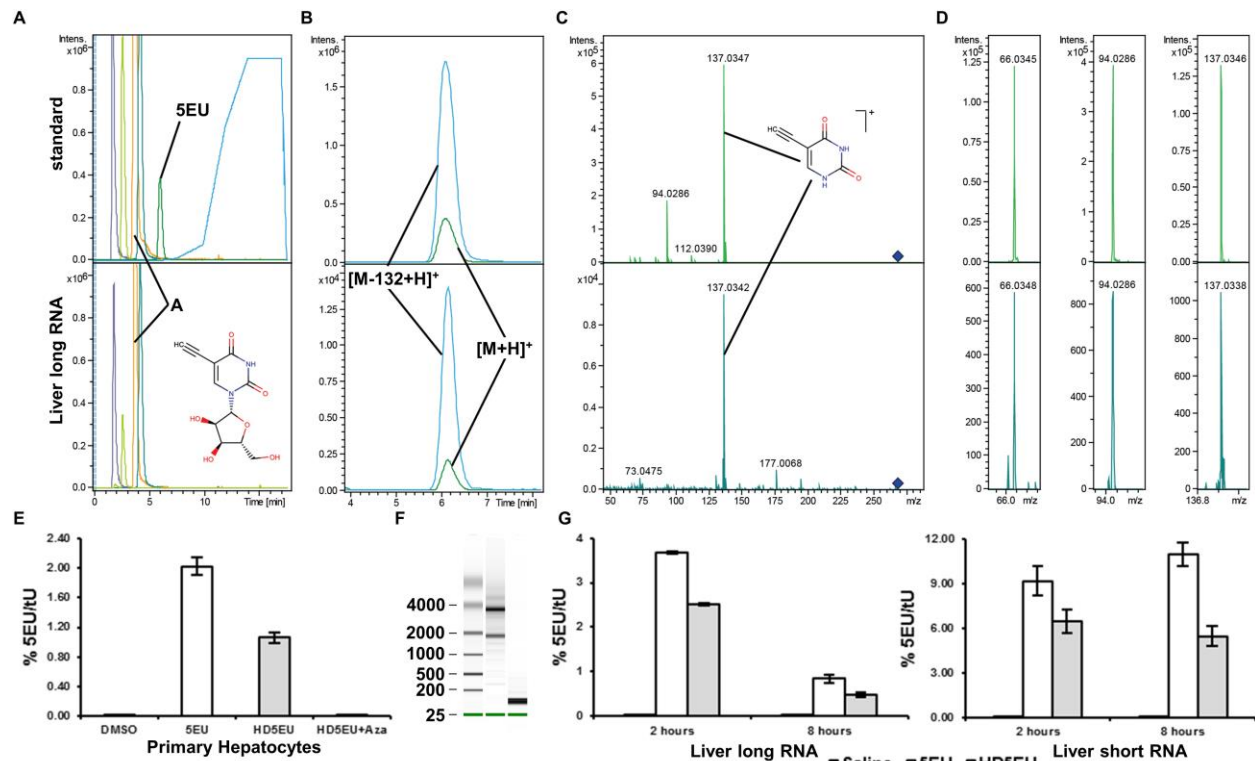

202

Darr J. et. al.

A) Extracted ion chromatograms from A, C, G, U and 5EU and gradient slope. **B)** Close up of extracted ion chromatograms of 5EU $[M+H]^+$ and 5EU in-source fragment $[M-132+H]^+$. **C)** Tandem MS spectra at 20 eV of standard and sample indicating main fragment $[M-132+H]^+$. **D)** Further fragments at 40eV used for identification of 5EU in RNA samples. **A-D** upper panels depict standard, lower panels depict liver long RNA from HD5EU treated mice. **E)** Relative quantification of 5EU in primary hepatocytes treated for 8h with the indicated compounds. Azamulin treatment inhibits CYP3A4 mediated HD5EU metabolism to 5EUMP and its subsequent incorporation into RNA. **F)** Bioanalyzer image depicting isolation of liver long and short RNA. **G)** Relative quantification of 5EU in liver derived long / small RNA following indicated time after 5EU / HD5EU administration to mice. Error bars indicated standard deviation calculated for 3 biological replicates.

Robustness and reproducibility of RNA precipitation.

2 hours following administration of HD5EU, 5EU-containing liver and kidney transcripts can be biotinylated and pulled-down for next generation sequencing. We persistently failed to generate any amplified libraries following pull-down of unlabeled RNA isolated from liver, plasma or

8

Darr J. et. al.

221   kidney of saline treated control mice **(Sup. Figure 3a-e)**. In addition, following a 2 hour treatment

222   with HD5EU we failed to generate libraries following biotinylation and pull-down from plasma

223   and from additional tissues of the HD5EU-treated mice, this in contrast to liver and kidney where

224   expected library amplicons were generated **(Sup. Figure 3a-e)**. This result was consistent for both

225   poly-A enriched and small RNA libraries and suggests biotinylation to be specific for 5EU

226   containing transcripts. Technical replicates of pull-down libraries demonstrated a high degree of

227   correlation between themselves, supporting the technical robustness and reproducibility of the

228   method **(Sup. Figure 3f,** spearman correlation coefficient = 0.95**)**.

229   To further assess the levels of non-specific RNA pull-down, we prepared a 10:1 mixture of non-

230   labeled small RNAs from *S. Cerevisiae* with labeled small RNAs derived from mouse liver.

231   Library construction and sequencing of this mixture following RNA pull-down demonstrated

232   highly effective depletion of yeast RNA compared to input **(Figure 4a)**. These results demonstrate

233   RNA pull-down to be highly selective to biotinylated RNA and non-specific RNA precipitation to

234   be extremely low to not detectable.

235

236   **RNA labelling in-vivo uncovers tissue architecture and stress induced transcriptional**

237   **reprogramming.**

238   We continued to examine if in-vivo labeling enriches for transcriptional programs of specific

239   cellular populations within complex tissues in-vivo, such as the proximal renal epithelial cells in

240   the kidney and hepatocytes in liver, and whether detection of environmentally induced

241   transcriptional reprogramming is possible. To this end we fed mice with high fat (**HFD**) or control

242   low fat (**LFD**) diets for two weeks. Following this acute HFD exposure, which is expected to alter

243   the transcriptional program in the liver [42], we administered HD5EU 2 hours before sacrificing.

244   We then continued to generate poly-A RNA libraries from kidney and liver input and pull-down

245   RNA.

246   Following mapping with the STAR aligner [43], transcript quantification using HTSeq-count and

247   differential pull-down analyses using the NOISeq package [44], we defined pulled-down

248   transcripts as those whose abundance can be estimated with a high degree of confidence to be at

249   least half of the abundance observed in input (i.e. at least 50% of the gene's transcripts are labeled

250   with a probability cut-off of 0.975) (**Figure 4b-g, Sup. table 2**).

9

Darr J. et. al.

251   In kidney, where proximal renal epithelial cells are labelled, GO annotation and gene set
252   enrichment analysis using Enrichr [45] demonstrated an enrichment for genes localized to the
253   brush boarder membrane, along with a few more general terms found enriched also in input such
254   as mitochondria, focal adhesion and genes specific to or highly expressed in the kidney **(Figure**
255   **4b-c, Sup. table 3)**. The brush boarder membrane in the kidney is a unique feature of proximal
256   renal epithelial cells [46], and among pulled-down transcripts, the Solute Carrier Family 9 member
257   A3 (Slc9a3) is one of its specific markers. Slc9a3 is the sodium–hydrogen antiporter 3, which is
258   highly expressed in the proximal tubule and allows active transport of sodium to the cell. Terms
259   uniquely enriched in genes depleted following pull-down include genes associated with ribosomal
260   function, genes specific to or highly expressed in CD34 positive cells, dendritic cells as well as
261   genes associated to neutrophil ficolin granules. CD34 positive cells are likely endothelial cells
262   found in glomeruli and blood vessels in both human and mice but absent from tubules [47, 48].
263   In liver, enrichment for identified liver targets of the nuclear receptors PPARA, LXR and RXR is
264   evident in both depleted and pulled-down transcripts. Pulled-down transcripts demonstrate
265   additional enrichment for identified liver targets of transcription factors such as Foxo1, Clock and
266   Nucks1 and for transcripts localizing to nuclear speckles and nucleoli **(Figure 4d-e, Sup. table 4)**.
267   LXR and RXR are implicated in lipid metabolism and heterodimerize to regulate gene expression.
268   Their transcriptional upregulation is associated with increased hepatic lipogenesis [49]. PPARA
269   instead, binds long chain free fatty acids and is a central regulator of lipid metabolism. It
270   heterodimerizes with RXR or LXR to regulate mitochondrial and peroxisomal fatty acid oxidation
271   [50-52].
272   Published single-cell sequencing from kidney [53] and liver [54] supports depletion of genes
273   associated with irrelevant cell types in both organs. Using published single-cell data, we compared
274   the top ranking genes defined in each study to be cluster specific markers to our pull-down
275   enrichment results. In kidney, we find the majority of cluster markers to be depleted following
276   pull-down of kidney poly-A RNA, apart from a small subset of markers for proximal tubule cells
277   **(Figure 4f)**. In liver, this trend continued and from the list of cluster specific markers, 80% of
278   those identified as enriched following liver poly-A RNA pull-down were defined as markers of
279   hepatocyte clusters.

Darr J. et. al.

280   Taken together these results support specific labelling of renal proximal tubule epithelial cells in

281   the kidney and of hepatocytes in the liver, with enrichment of their transcriptomes in pulled-down

282   RNA and specific depletion for genes associated with other cell types found in these organs.

283   To assess the feasibility of detecting dynamic transcriptional responses using iTag-RNA, we

284   examined whether diet-induced transcriptional reprogramming can be identified in pulled-down

285   poly-A RNA, and to what extent it reflects transcriptional changes observed in whole-tissue input

286   RNA. Differential gene expression analyses using the DEseq package [55] revealed a substantial

287   overlap between diet induced transcriptional reprogramming in the liver as observed in input

288   mRNA to transcriptional reprogramming observed in pull-down libraries **(Figure 4g, Sup. table**

289   **5)**. Though the total amount of differentially expressed genes **(DEG)** was roughly 4 fold lower in

290   pull-down vs. input libraries (157 vs. 636 DEG, with an FDR cutoff of less than 0.05 and absolute

291   log2 fold change greater than 1), a 61% overlap (96 DEG) between the two sample sets was

292   detected. This overlap is much higher than expected by chance (chi test <0.0001). Diet induced

293   DEG in both input and pull-down liver RNA demonstrated a significant enrichment for genes

294   regulated by PPARA, LXR and RXR **(Figure 4h and Sup. Table 7)**.

295   As opposed to liver, diet-induced differential expression in the kidney was limited to 108

296   transcripts in input poly-A RNA enriched for mitochondrial and ribosomal proteins, whilst pulled-

297   down RNA demonstrated no transcriptional reprograming **(Figure 4i-j, Sup. table 6-7).** These

298   findings may reflect the more complex cellular composition of the kidney and a lack of

299   transcriptional reprogramming in proximal renal epithelial cells.

300   Taken together, these results provide a proof-of-concept that iTAG-RNA allows isolation of cell-

301   type specific transcriptional responses to environmental challenges. Importantly, with no need for

302   the disruption of the tissue architecture or interference with the cellular microenvironment.

336

337 **Hepatocyte derived ccfRNA are detected in Plasma**

338 Given the observed hepatic transcriptional reprogramming following a HFD challenge, we

339 examined whether we can detect labeled hepatocyte derived plasma ccfRNAs, and if the profile of

340 these secreted transcripts changes in response to the dietary challenge. Plasma isolated ccfRNAs

341 are predominantly short / fragmented RNA transcripts with a bi-modal distribution and a major

342 peak smaller than 200bp ([56] **and sup figure 3g**). As already described, with a single dose of

343 HD5EU 2 hours before blood collection we failed to generate libraries from plasma ccfRNA

344 following biotinylation and pull-down. However, with multiple doses of HD5EU administration

345 6, 4 and 2 hours before blood collection, we were able to generate small RNA libraries following

346 pull-down of plasma ccfRNAs.

13

347 Multiple short RNAs were pulled-down in both liver and plasma under HFD and LFD. (**Figure**
348 **5a,** 459/992 for HFD and 234/700 for LFD). This co-occurrence rate is greater than expected by
349 chance for HFD and LFD **(Figure 5a,** P.V calculated using the SuperExactTest package in R [57],
350 Fold enrichment = HFD: 2.7; LFD = 1.8; P.V. = HFD: 4.3e-104; LFD = 6.42e-21). The identity of
351 pulled-down plasma ccfRNAs varied between dietary challenges **(Figure 5b and Sup. tables 8-**
352 **10)**, with multiple reads found enriched only under a specific dietary challenge, suggesting that
353 liver secreted ccfRNAs indeed change with dietary interventions.

354 Various biotypes are identified in pulled-down liver and plasma short RNA libraries, with the
355 relative proportion of pulled-down transcripts varying between the two. tRNAs, mitochondrial
356 tRNAs and mitochondrial genes are found to be overly represented in pull-down RNA from plasma
357 relative to liver (**Figure 5c**). This result suggests that the majority of mitochondrial transcripts
358 found in plasma originate predominantly in the liver.

359 Additional support in favor of the hepatic origin of plasma labeled transcripts can be found in
360 fragments originating from protein coding genes. These protein coding fragments demonstrate a
361 significant enrichment for liver specific and highly expressed genes, whilst transcripts
362 constitutively depleted in pull-down RNA demonstrate an enrichment for bone marrow specific
363 protein coding fragments, genes related to hematopoietic differentiation and genes specific to
364 neutrophil function. **(Figure 5d and sup. table 11)**. This result may suggests that the
365 hematopoietic system is one of the major contributors of circulating RNAs. HFD and LFD specific
366 pulled-down protein coding transcripts demonstrate differential enrichment for annotations
367 including adipocytokine signaling and mitochondrial electron transport respectively (**Figure 5e**).
368 The significant enrichment found for liver specific protein coding genes among pulled-down
369 transcripts supports the hypothesis that pulled-down ccfRNA transcripts originate in hepatocytes,
370 where Cyp3a4 expression metabolizes HD5EU to 5EU, allowing its incorporation into nascent
371 transcribing RNA.

372

Darr J. et. al.

Figure 5. Identification of hepatocyte secreted circulating transcripts in Plasma. A) Overlap between pulled-down small RNA transcripts in liver and plasma under HFD and LFD challenge. Number of transcripts per overlap indicated in the y-axis. Color corresponds to −log$_{10}$ of calculated P.V and is annotated in the chart. Gene sets included in each comparison are indicated in green. **B)** Scatter plot annotating selected miRNAs and mt-tRNAs identified as pulled-down in circulating plasma RNA under HFD and LFD conditions. Transcripts are either depleted following pull-down regardless of dietary regime (purple), pulled-down regardless of dietary regime (green) or pulled-down under HFD (red) or LFD (blue) dietary regimes only. **C)** Bubble plot representing the relative percentage of pulled-down transcripts per biotype in liver and plasma libraries, averaged across HFD and LFD regimes. Bubble size represents log10 of actual number of transcripts per bio-type. Error bars for standard deviation between sets. **D)** Bubble plot of GO and gene set enrichment analysis for constitutively pulled-down (green) and depleted (purple) cell-free circulating transcripts. Bubble size proportional to −log$_{10}$ of adj. PV. **E)** Bubble plot of GO and gene set enrichment analysis for cell-free circulating transcripts pulled-down in HFD (red) or LFD (blue). Bubble size proportional to −log$_{10}$ of adj. PV.

Hepatic derived ccfRNA are found in visceral white adipose tissue where they contribute to the small RNA pool and potentially regulate lipid storage

15

Darr J. et. al.

392 In worms, plants and prokaryotes, extracellular RNA signaling was described to modulate
393 host/pathogen interactions and to orchestrate an adaptive response to environmental stimuli [58-
394 60], and demonstrated the idea that biological systems can exist as holobionts characterized by
395 continuous exchange of genetic (DNA, RNA) material. In mammals, RNA-based intercellular
396 signaling has been described in several settings [4, 9, 12, 61-63], using mostly in-vitro systems or
397 ectopic administration of RNAs to demonstrate RNA transfer and signal transduction. Little is
398 known on the extent of RNA transfer in-vivo and on the role it may play in physiological settings.
399 Two weeks of high-fat diet feeding are sufficient to impair metabolic homeostasis [64], and induce
400 morpho-functional alterations in both liver and visceral adipose tissue [64]. Given the central role
401 liver and adipose tissue play in metabolic control [65], and existing evidence suggesting RNA-
402 based signaling between the tissues [12], we used iTAG-RNA to identify diet-sensitive RNA-
403 based liver-to-adipose signals.

404 The number of transcripts found to be enriched following pull-down in liver, plasma and VsWAT
405 was 9.7 folds greater than expected by chance for HFD and 6.8 folds greater than expected for
406 LFD (HFD: 264/27, PV=6.34e-180 ; LFD: 116/17, PV = 3.7e-59 as calculated using the
407 SuperExactTest package in R [57]) **(Figure 6a Sup tables 8-10)**. Focusing on identified hepatic
408 transcribed plasma ccfRNAs, multiple small RNAs could be enriched for in VsWAT. These
409 include miRNAs such as mir-33, mir-10b and mir-130a, in addition to mt-tRNAs (**Figure 6b)**.
410 Among experimentally validated targets of the identified miRNAs (as annotated by miRTarBase
411 [66]), an enrichment is found for proteins associated with the GO term negative regulation of lipid
412 storage (GO:0010888, adj. P.V. = 0.0078, enrichment score = 26.68) such as Abca1, Ppara and
413 Pparg which are regulated by mir-33 [23, 24], mir-10b [25] and mir-130a [26, 67] respectively.
414 Mir-33 is also an identified regulator of the Srebp family of transcription factors that are central
415 in cholesterol and fatty acid synthesis [68, 69] and is in fact encoded within the intron of Srebf2.
416 Total RNA sequencing of VsWAT identified 100 genes to be differentially expressed following
417 acute HFD feeding (28 upregulated / 72 downregulated, **Sup table 12**). As expected given the
418 increased dietary intake of free fatty acids following HFD feeding, downregulation of Srebf1 and
419 of several target genes involved in fatty acid biosynthesis such as FasN, Acaca, and Scd2 is evident
420 (**Figure 6c-d**).

421 Based on the described literature on intercellular RNA signaling, two main effects can be
422 envisaged for the transfer of ccfRNAs between tissues: 1. Direct alterations to a cell's

16

423   transcriptomic pool via introduction of novel regulatory RNAs, and 2. Modulation of existing

424   intracellular pools of regulatory RNAs. Both scenarios can have varying degrees of functional

425   consequences on the transcriptional and physiological responses of the recipient cell.

426   To explore these two possibilities, we looked at the expression levels in VsWAT of the identified

427   miRNAs. Paradoxically, both small RNA-Seq and qRT-PCR (Fig.6e) confirmed that rather than

428   upregulation of these miRNAs in VsWAT following HFD, no change or a moderate

429   downregulation in their levels is evident. This result most likely reflects a HFD-induced

430   downregulation of the endogenously transcribed adipocyte miRNAs and suggests that the transfer

431   of exogenous hepatic derived miRNAs buffers the downregulation of the adipocyte transcribed

432   miRNAs. Indeed upon acute HFD feeding and in keeping with mir-130a downregulation and

433   published results, Pparg protein but not transcript levels are modestly upregulated (**Figure 6d, f**).

434   All together, these results show – for the first time – transfer of regulatory RNAs from hepatocytes

435   to adipocytes in response to acute dietary challenge and suggest a potential function in buffering a

436   cell's transcriptional and physiological responses.
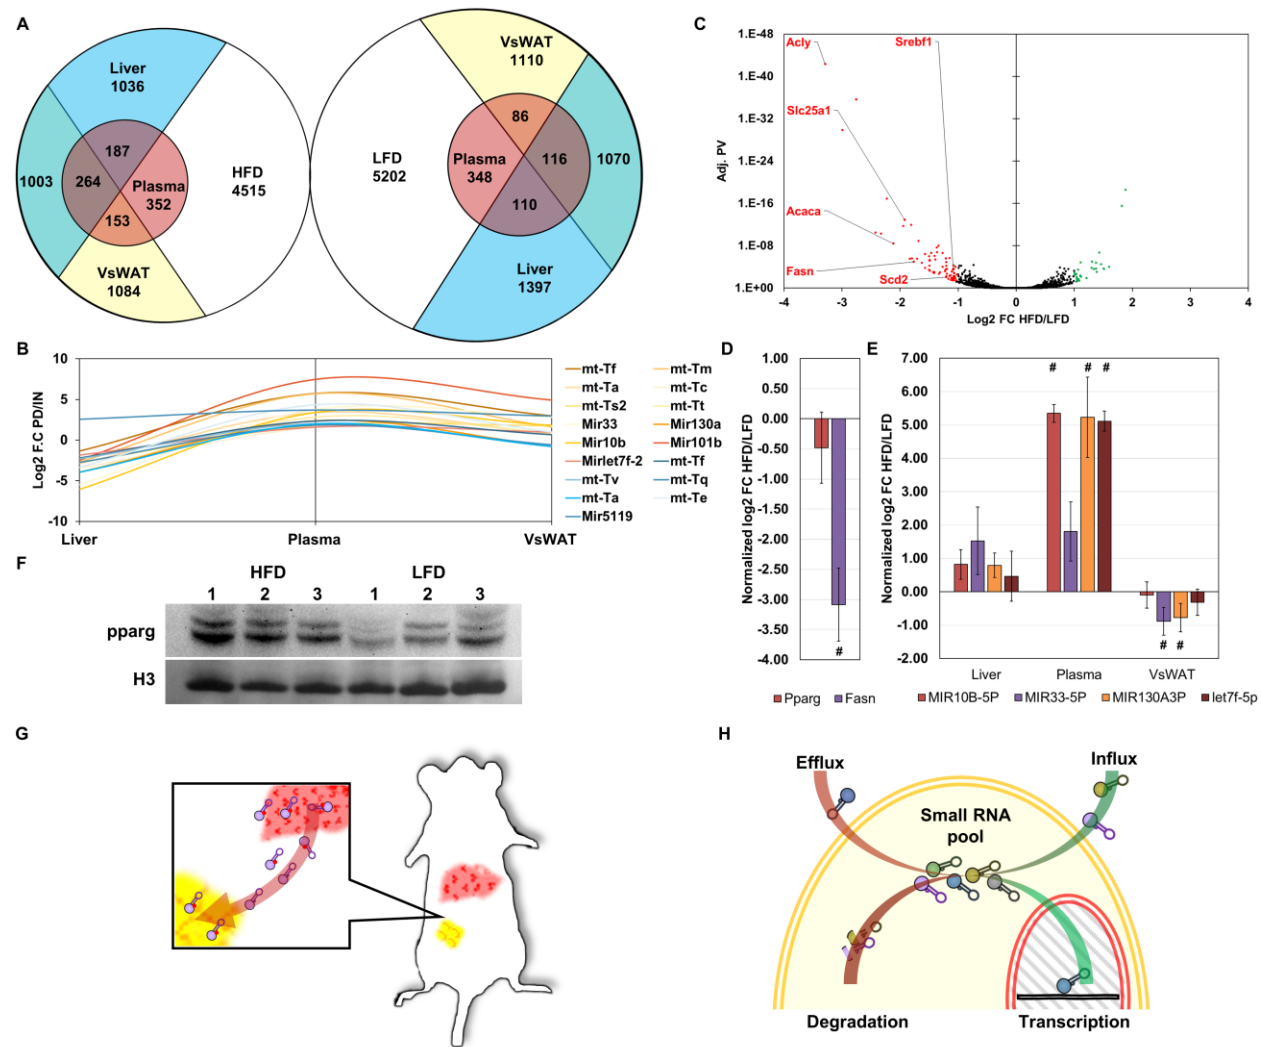

Darr J. et. al.

Figure 6. Plasma ccfRNAs can be detected in VsWAT. A) Venn diagram demonstrating the overlap between pulled-down transcripts in expression sets from liver plasma and VsWAT for HFD and LFD (Blue = Liver; Red = Plasma; Yellow = VsWAT). B) miRNAs and mt-tRNAs that are pulled-down in both plasma and VsWAT (Red = HFD; Blue = LFD). C) Volcano plot demonstrating DEG in total RNA sequencing of VsWAT following 2 weeks of HFD or LFD challenge. Red – downregulated in HFD, Green – Upregulated in HFD. D) qRT-PCR estimations for differential expression of Pparg and Fasn in VsWAT. # = significant fold change, n=3. E) qRT-PCR estimations for differential expression of selected miRNAs. # = significant fold change, n=3. F) Western blot for Pparg, modest upregulation of Pparg levels is evident following 2 weeks of HFD. G) Depiction of small RNA transfer between liver and adipose tissue. H) A model suggesting that the small RNA pool within a cell results from a balance between transcription and degradation on the one hand and influx and efflux on the other.

450

451 **Discussion**

452 In this work we present **iTAG-RNA**, a novel method for targeted in-vivo labelling of global RNA

453 transcription, and use it to identify hepatocyte secreted ccfRNA and their uptake by adipose tissue

454 in-vivo. iTAG-RNA allows labelling of total RNA transcripts in-vivo using two main components:

455 **HD5EU**, a newly designed small molecule that serves as a metabolite for the human CYP3A4

456 enzyme; and **an existing humanized transgenic mouse model** expressing the human CYP3A4

457 enzyme under a modified APOE promoter **(Figure 1)**. CYP3A4 catalyzes the oxidative cleavage

458 of an aryl group of the HD5EU molecule, which in turn undergoes spontaneous beta elimination

459 to produce a bio-available 5EU-monophosphate. The existing transgenic mouse model allows in-

460 vivo labelling of hepatocytes and kidney proximal renal epithelial cells **(Figure 2),** as the tissue

461 expression pattern of the enzyme dictates the site of the small molecule's metabolism and

462 subsequent RNA labeling. To validate the specificity of HD5EU metabolism, we demonstrate that

463 HD5EU is indeed metabolized in a CYP3A4 dependent manner to 5EU-monophosphate. 5EU is

464 then incorporated in place of uridine into transcribing RNA **(Figure 2-3)** and allows highly

465 selective RNA precipitation and sequencing of labeled RNAs (**Sup. Figure 3 and Figure 4a**).

466 Development of new transgenic models would allow for labeling of multiple tissues of choice.

467 Administration of HD5EU allows enrichment for the transcriptional program of proximal renal

468 epithelial cells and hepatocytes in-situ without disruption of the kidney or liver architecture

469 **(Figure 4b-g)**. In addition, environmentally induced transcriptional reprogramming is evident

470 following labelling (**Figure 4h-k**). As opposed to recently described methods [14, 17, 20, 22] and

471 in keeping with the literature where POLI, POLII and POLIII are demonstrated to incorporate 5EU

472 [27], mRNA and small RNAs of various types including rRNA, tRNA and miRNA are found to

473 be labeled and enriched in pulled-down RNA.

474 Critically, and uniquely to iTag-RNA, we are also able to enrich for liver derived plasma ccfRNA

475 following an administration of multiple doses of HD5EU **(Figure 5)**. Pulled-down plasma

476 ccfRNAs demonstrate an enrichment for liver derived RNA fragments of protein-coding genes,

477 whilst depleted transcripts demonstrate an enrichment for annotation relating to function and

478 differentiation of the hematopoietic system. Apart from fragments of protein coding genes, liver

479 secreted ccfRNA include various small RNA transcripts such as miRNA, mt-tRNAs and tRNAs.

480 Given the evident enrichment for mitochondrial transcripts following pull-down, our results

19

481 suggest that hepatocytes are the main source of mitochondrially encoded ccfRNA transcripts in
482 plasma. The functional significance of these tRNA fragments is unclear, but several studies have
483 suggested tRNAs and tRNA fragments can mediate cellular signaling, and that the overall tRNA
484 pool and composition within a cell has functional significance [70].

485 We continued to explore the possibility that ccfRNAs are taken up by tissues in-vivo to mediate
486 cell-to-cell communication. Focusing on VsWAT we pulled-down and amplified labeled RNA,
487 again following multiple doses of HD5EU (**Figure 6a**). The transcripts we identified as labeled in
488 VsWAT demonstrated a greater overlap than expected by chance with labeled plasma ccfRNAs or
489 indeed with labeled transcripts in the liver, supporting their hepatic transcriptional origin. These
490 transcripts including miRNAs and mt-tRNAs **(Figure 6b),** with the identified miRNAs implicated
491 in post-transcriptional regulation of proteins involved in lipid, cholesterol and fatty acid pathways.
492 Together our results directly demonstrate for the first time, in-vivo transfer of a large variety of
493 RNAs including miRNAs between hepatocytes and visceral adipose tissue (**Figure 6g**), with the
494 identity of transferred RNAs varying following an acute dietary challenge. In light of the observed
495 diversity and scope of RNA transfer between hepatocytes and adipocytes, our results suggest that
496 the pool of small RNAs in a cell in-vivo results from a balance not only between transcription and
497 degradation, but also influx and efflux of small RNAs from the extracellular environment (**Figure
498 6h**), with the latter serving as a buffering mechanism for transcriptional and physiological
499 responses in target cells.

500 To date, the majority of potential ccfRNA biomarkers associated with liver pathologies have been
501 miRNAs [71]. Our findings suggest that fragments of protein coding genes together with
502 mitochondrial tRNAs and mitochondria encoded transcripts can also serve as useful biomarkers
503 for hepatic function. Development of additional genetic models similar to the one used can allow
504 for better transcriptional characterization of distinct cell populations in-vivo, with the added
505 benefit of labelling endogenous ccfRNAs in-vivo. Lastly, HD5EU may prove beneficial in clinical
506 settings. As metabolic activation of HD5EU requires the human Cyp3a4 enzyme, whose
507 expression under physiological conditions is largely limited to the liver (The human protein atlas.
508 2019. CYP3A4. [ONLINE] Available at: https://www.proteinatlas.org/ENSG00000160868-
509 CYP3A4/tissue/primary+data **[72]**), administration of this small molecule to humans may
510 constitute a novel diagnostic tool allowing assessment of hepatic function by means of a liquid
511 biopsy.

Darr J. et. al.

512

Methods:

Mice handling:

Mice were purchased from Taconic (Taconic USA). All mice were kept in a SPF facility in accordance with the Bavarian Animal law. Mice were fed with a chow / high fat diet / low fat diet as indicated (Rodent Diet with 60 kcal% from fat - Research Diet D12492i, Rodent Diet with 10 kcal% from fat − Research Diet D12450B). 5EU (7848.2, Carl Roth) was solubilized in saline 0.9% NaCl, HD5EU in a 25 % PEG-400, 5% DMSO saline solution. Compounds were administered intraperitoneally at a dose of 0.15 / 0.3$_{mg/g}$ in a total volume of 200µl. First administration was always carried out at ZG-3 to avoid circadian effects. For blood and organ collection, mice were terminally anesthetized with Ketamin/Xylazine at indicated times following drug administration. Heart puncture was performed to collect blood in EDTA coated syringes. Blood was centrifuged at 4.8K rpm for 10' followed by 12K rpm at 20' and filtration through a 22uM PES filter (PA59.1, Carl Roth). For isolation of primary hepatocytes, mice were anesthetized and liver perfused through the vena cava with Gibco's liver perfusion buffer (17701-038, Gibco) and liver digestion buffer (17703-034, Gibco) in accordance with manufacturer's instructions.

Cell culture:

Isolated primary hepatocytes were counted using the countess automated cell counter (C10227, invitrogen), and plated to a density of 75k/Cm^2 on Geltrex (A1413201, ThermoFisher) coated coverslips (200 µg/cm^2) in Williams' Medium E (A12176, Gibco) supplemented with Gibco's Primary Hepatocyte Maintenance Supplements (CM4000, Gibco). 24 hours following plating, cells were treated with 1mM of 5EU or HD5EU for 8 hours. Azamulin (SML0485, Sigma Aldrich) was added at a concentration of 20µM for 30 minutes before addition of indicated compounds to a final concentration of 10µM for the length of the treatment.

Tissue processing and imaging

Tissues were fixed in a neutral buffered 10% formalin solution (HT501128, Sigma) for 48 hours before dehydration and embedding in paraffin in accordance with published protocols. 4µm sections were cut on a Leica microtome (RM2165, Institute of Experimental Genetics), rehydrated and stained using the Click-iT™ RNA Alexa Fluor™ 594 Imaging Kit (C10330, ThermoFisher)

21

543 in accordance with manufacturer's instructions. Mounting was done with Vectashield hardset

544 antifade mounting medium with DAPI (H-1500, Vector Laboratories). Imagining was done using

545 a Laser Scanning Confocal Microscope (Olympus Fluoview 1200, Institute for Diabetes and

546 Cancer, Neuherberg, Germany) equipped with an Olympus UPlanSApo 60x 1.35 Oil immersion

547 objective.

548

549 *Western Blot*

550 Tissues were homogenized using a Miltenyi gentleMACS Dissociator (Miltenyi biotec) in RIPA

551 buffer supplemented with protease (S8820, Sigma Aldrich) and phosphatase (88667, Thermo

552 Fisher) inhibitors. Protein concentration was measured using a standard Bradford assay reagent

553 (B6916, Sigma Aldrich).40µg total protein were loaded per samples on a pre-cast gradient 4-12%

554 gel (NW04120, Invitrogen). Proteins were transferred to a PVDF membrane (ISEQ00010, Merck

555 Millipore) blocked and blotted using the iBind system (SLF1020, Invitrogen) with primary anti-

556 CYP3A4 (MA5-17064, Thermo Fisher), anti-Phospho-p53 S392 (#9281, cell signaling), anti-

557 total-p53 (#2524, cell signaling), anti-cleaved Caspase-3 (ab214430, abcam) , anti-total Caspase-

558 3 (#ab184787, abcam), anti-pparg (MA5-14889, Thermo Fisher), anti-histone H3 (4499s, cell

559 signalling) and anti-HSP90 (SC-7949, Santa-Cruz), and secondary IgG HRP (7076 and 7074, Cell

560 Signaling)

561

562 *RNA extraction, qRT-PCR, pull-down and library construction.*

563 Plasma RNA was extracted using TRI Reagent BD (T3809, Sigma Aldrich), in accordance with

564 manufacturer's instructions. RNA from tissues was extracted using NucleoZOL (740404.200,

565 Macherey-Nagel) reagent, in accordance with manufacturer's instructions. For qRT-PCR, reverse

566 transcription was conducted using the high-Capacity cDNA Reverse Transcription Kit (4368814,

567 Applied Biosystems), in accordance with the manufacturer's instructions. Real-time was carried

568 out on a quant-studio 6 flex (applied biosystems) with SYBR Green PCR Master Mix (#4309155

569 applied biosystems) and primers; hCyp3-F: TTGGCATGAGGTTTGCTCTC; hCyp3-R:

570 ACAACGGGTTTTTCTGGTTG; Pparg-F: AGATTCTCCTGTTGACCCAGAG; Pparg-R:

571 AGCTGATTCCGAAGTTGGTG; Fasn-F: CTGCTGTTGGAAGTCAGCTATG; Fasn-R:

572 ATGCCTCTGAACCACTCACAC; Actin-F: CACAGCTTCTTTGCAGCTCCT; Actin-R:

573 CAGCAGTGCAATGTTAAAAGG; qRT-PCR for miRNAs was conducted as previously

574 described [73] and primers designed with miRprimer2 [74]. miR-7f-5p-F:

575 CGCAGTGAGGTAGTAGATTG; miR-7f-5p-R: CAGGTCCAGTTTTTTTTTTTTTTTAAC;

576 miR-130a-3p-F: CAGCAGTGCAATGTTAAAAGG; miR-130a-3p-R:

577 CAGGTCCAGTTTTTTTTTTTTTTTATG; miR-33-5p-F: CGCAGGTGCATTGTAGT; miR-

578 33-5p-F:GTCCAGTTTTTTTTTTTTTTTGCAAT; miR-10b-5p-F

579 CAGTACCCTGTAGAACCGA; miR-10b-5p-R:GGTCCAGTTTTTTTTTTTTTTTCAG; Pull-

580 down of 5EU labeled RNA was done using the Click-it Nascent RNA Capture Kit (C10365,

581 Thermo Fisher). 10µg total / small RNA was used as input from tissues, 200ng plasma RNA was

582 used as input for RNA pull-down from blood. RNA was used as template for library construction

583 using the CATS mRNA/small RNA kit (C05010043 and C05010040, Diagenode) with slight

584 modifications to protocol i.e.; Poly-A selection and RNA fragmentation were performed before

585 biotinylation and pull-down of 5EU. 14 cycles of amplification for RNA from tissues, 20 for RNA

586 from blood. 10ng of RNA was used for Input. For MS analysis, 10µg long / short RNA was used.

587 RNA was digested as described in Sue et. al. [41].

588

589 *UPLC-UHR-ToF-MS analysis*

590 Mass spectrometric analysis of nucleotides from RNA was performed on a Waters Acquity UPLC

591 (Waters, Eschborn, Germany) coupled to a Bruker maXis UHR-ToF-MS (Bruker Daltonic,

592 Bremen, Germany). Separation was performed on a Thermo Hypersil Gold column (150 x 1.0 mm,

593 3 µm, 25003-151030, Thermo Fisher) using a multistep gradient with 100% water and 100% ACN,

594 both with 0.1% formic acid. Gradient conditions were as followed: 0-6 min 0% B, 6-7.65 min

595 linear increase to 1% B, 7.65 to 10 min linear increase to 6% B, 10 to 12 min linear increase to

596 50% B, 12 to 14 min linear increase to 75% B, 14 to 17 min isocratic hold of 75% B, 17 to 17.5

597 min return to initial conditions. Column temperature was 36°C and flow rate was set to 0.09

598 ml/min. Before each run the column was re-equilibrated for 3 minutes with starting conditions.

599 High mass accuracy was achieved by infusion of 1:4 diluted ESI low concentration tune mix

600 (Agilent Technologies, Waldbronn, Germany) at the start of each chromatographic run. Each

601 analysis was internally recalibrated using the tune mix peak at the beginning of the chromatogram

602 using a custom VB script within Bruker DataAnalysis 4.0 (Bruker Daltonic, Bremen, Germany).

603 Quantitative analysis was performed in Bruker QuantAnalysis 4.0 (Bruker Daltonic, Bremen,

604 Germany). High Resolution-Extracted Ion Chromatograms (HR-EICs) were created around each

605　precursor mass +/- 0.005 Da. Chromatograms were smoothed and peak areas were used for

606　quantification. In case of 5EU additional quantification was performed on a validated in-source

607　fragment [M-132+H]$^{+}$.

608

609　*Bioinformatic analysis*

610　RNA Libraries were sequenced on an Illumina HiSeq 2500 instrument (**IGA Technology Services**

611　**Srl, Italy)** at 75bp single-ended**.** Adaptors were trimmed in accordance with the CATS sequencing

612　kit manual. Reads were aligned to the mouse mm10 genome using the STAR aligner [43] and a

613　reference transcript gtf file from ensamble modified to contain tRNA transcripts as annotated by

614　GtRNAdb [75].

615　For the detection of differentially regulated genes between HFD and LFD the Deseq2 package was

616　used [55]. Pull-down enrichment analysis was conducted using the NOISeq package. Transcripts

617　with expression values smaller than a cpm of 1 and a coefficient of variation greater than 300 were

618　filtered out prior to tmm normalization and enrichment analysis. GO and gene set enrichment was

619　calculated using the Enrichr tool [45].

680 **Supplementary table 7.** GO and gene set enrichment analysis on dietary induced differentially

681 expressed genes in liver and kidney pull-down or depleted poly-A RNA.

682 **Supplementary table 8.** Noiseqbio differential pull-down analysis for liver, plasma and VsWAT

683 under HFD regime. TMM normalized mean expression values.

684 **Supplementary table 9.** Noiseqbio differential pull-down analysis for liver, plasma and VsWAT

685 under LFD regime. TMM normalized mean expression values.

686 **Supplementary table 10.** SuperExacttest package output. Overlaps between different sets and

687 calculated P.V.

688 **Supplementary table 11** GO and gene set enrichment analysis on plasma pulled-down protein

689 coding genes.

690 **Supplementary table 12** Differential expression analysis using Deseq2 package, for the detection

691 of dietary induced DEG in total VsWAT RNA.
