Abstract

Pathogens infecting plants and animals use a diverse arsenal of effector proteins to suppress the host immune system and promote infection. Identification of effectors in pathogen genomes is foundational to understanding mechanisms of pathogenesis, for monitoring field pathogen populations, and for breeding disease resistance. We identified candidate effectors from the lettuce downy mildew pathogen, *Bremia lactucae*, using comparative genomics and bioinformatics to search for the WY domain. This conserved structural element is found in *Phytophthora* effectors and some other oomycete pathogens; it has been implicated in the immune-suppressing function of these effectors as well as their recognition by host resistance proteins. We predicted 54 WY domain containing proteins in isolate SF5 of *B. lactucae* that have substantial variation in both sequence and domain architecture. These candidate effectors exhibit several characteristics of pathogen effectors, including an N-terminal signal peptide, lineage specificity, and expression during infection. Unexpectedly, only a minority of *B. lactucae* WY effectors contain the canonical N-terminal RXLR motif, which is a conserved feature in the majority of cytoplasmic effectors reported in *Phytophthora* spp. Functional analysis effectors containing WY domains revealed eleven out of 21 that triggered necrosis, which is characteristic of the immune response on wild accessions and domesticated lettuce lines containing resistance genes. Only two of the eleven recognized effectors contained a canonical RXLR motif, suggesting that there has been an evolutionary divergence in sequence motifs between genera; this has major consequences for robust effector prediction in oomycete pathogens.

Author Summary

There is a microscopic battle that takes place at the molecular level during infection of plants and animals by pathogens. Some of the weapons that pathogens battle with are known as "effectors," which are secreted proteins that enter host cells to alter physiology and suppress the immune system. Effectors can also be a liability for plant pathogens because plants have evolved ways to recognize these effectors, triggering a defense response leading to localized cell death, which prevents the spread of the pathogen. Here we used computer models to predict effectors from the genome of *Bremia lactucae*, the causal agent of lettuce downy mildew. Three effectors were demonstrated to suppress the basal immune system of lettuce. Eleven effectors were recognized by one or more resistant lines of lettuce. In addition to contributing to our understanding of the mechanisms of pathogenesis, this study of effectors is useful for breeding disease resistant lettuce, decreasing agricultural reliance on fungicides.

Introduction

The phylum Oomycota includes some of the most devastating pathogens of both plants and animals [1]. Although oomycetes resemble fungi in their filamentous growth and infection structures, they are more closely related to brown algae than to fungi [2]. Notable oomycetes include the plant pathogens causing late blight of potato (*Phytophthora infestans*) [3], sudden oak death (*Phytophthora ramorum*) [4], root rot (*Phytophthora* [5] and *Pythium* spp. [6,7]), white blister rust of *Brassica* spp. (*Albugo* spp.) [8], and downy mildews (e.g. *Bremia, Peronospora, Plasmopara* spp.) [9], as well as several important animal pathogens infecting fish (*Saprolegnia* spp.), shellfish

(*Aphanomyces astaci*), and mammals, including humans (*Pythium insidiosum*) [1,10]. Many types of plant and animal pathogens, including the oomycetes, secrete proteins known as effectors to promote virulence by manipulating the physiology of the host cells and by suppressing the host immune system [11]. In plants, effectors are also determinants of resistance or susceptibility through their direct or indirect interactions with cognate nucleotide-binding leucine rich repeat proteins (NLRs) encoded by resistance genes [12]. Effectors are secreted from the pathogen and may act extracellularly or they may be translocated into the cytoplasm [11]. One class of translocated effectors from plant pathogenic oomycetes of the class Peronosporales, which includes *Phytophthora* and the downy mildews, are the RXLR effectors, so called for their N-terminal motif usually consisting of arginine, followed by any amino acid, then followed by leucine and arginine. RXLR effectors also contain an N-terminal signal peptide, which designates them for extracellular transport by way of the endoplasmic reticulum and Golgi apparatus [13]. The RXLR motif is often associated with a downstream EER motif, both of which have been associated with secretion and/or translocation of effectors into the plant cell [13,14]. For some RXLR effectors, such as Avr3a, the RXLR motif has been shown to be cleaved just prior to the EER sequence and therefore plays a role in secretion rather than uptake into the host cell [15]. The RXLR motif is similar in sequence to the PEXEL motif (RXLX[EDQ]) of the distantly related malaria pathogen (*Plasmodium falciparum*) [16] and the TEXEL motif of *Toxoplasma gondii* (RRLXX) [17], both of which are required for proteolytic modification in the endoplasmic reticulum and destine effector proteins for specialized export out of the cell [18].

93 The downy mildews and the related *Phytophthora* species have different
94 lifestyles (obligate biotrophy *vs.* facultative hemibiotrophy) [19]; however, their
95 effectors share similar features. Many effectors in the Peronosporales have RXLR and
96 EER motifs; although several alternative sequences to RXLR have been found in
97 downy mildews, including RVRN (ATR5 from *Hyaloperonospora arabidopsidis*) [20],
98 QXLR (*Pseudoperonospora cubensis*) [21], GKLR (*Bremia lactucae*) [22,23], and RXLK
99 (*Plasmopara halstedii*) [24]. The C-terminal effector domains of RXLR effectors from
100 *Phytophthora* and downy mildews also share some common sequence motifs and
101 structural features, such as the 24 to 30 amino acid W, Y, and L motifs, which were
102 first identified bioinformatically [25]. Structural analysis on four different RXLR
103 effectors from *Phytophthora infestans* (Avr3a and PexRD2), *P. capsici* (Avr3a11), and
104 the downy mildew pathogen *H. arabidopsidis* (ATR1) revealed that the W and Y motifs
105 form an alpha-helical fold that may play a role in protein-protein interactions [26–
106 29]. This effector-associated fold, termed the WY domain after its conserved
107 tryptophan and tyrosine residues, is structurally highly conserved between effectors
108 from multiple Peronosporales species, despite sharing less than 20% sequence
109 similarity across the whole domain [26][30]. The WY domain appears to be specific
110 to the Peronosporales and was predicted to be present in nearly half of the RXLR
111 effectors of *P. infestans* and a fourth of the RXLR effectors in *H. arabidopsidis* [26].
112 Functional studies of WY domain containing proteins have indicated that
113 certain residues in the WY domain are essential for the immune suppressing
114 functions of *P. sojae* Avr1b [31], *P. infestans* Avr3a [32], and *P. infestans* PexRD2 [33].
115 Furthermore, mutation of two conserved leucines in the WY domain of PexRD2

disrupted interaction with its target, MAPKKKε, consistent with this domain being important for protein-protein interactions [33]. WY domain containing proteins appear to interact with a variety of host targets, with Avr3a from *P. infestans* targeting the E3 ligase CMPG1 [32], *P. infestans* PexRD54 targeting potato autophagy-related protein ATG8 [34], PsAvh240 from *P. sojae* targeting an aspartic protease [35], and PSR2 from *P. sojae* and *P. infestans* suppressing host RNA silencing through interactions with dsRNA-binding protein DRB4 [36–38]. Mutation analysis of the regions encoding the seven individual WY domains of PSR2 demonstrated differential contributions of each domain to virulence of *P. sojae*, suggesting that the WY domain may act as a module during effector evolution [30]. In addition to its roles in immune suppression, the WY domain has been shown to be important for immune recognition of the effector by nucleotide binding-leucine rich repeat (NB-LRR) resistance proteins [39].

Effector annotation in oomycete genomes has often relied on sequence similarity to known effectors or on prediction of conserved motifs, such as the RXLR motif, or in the case of Crinklers, the LXLFLAK motif [3]. Due to the short length and degeneracy of the RXLR sequence, the motif occurs frequently by chance; therefore, there is a high false positive rate (>50%) using string-based searches [25]. HMM-based searches have much lower false positive rates, but the false negative rate may be higher if the genome of interest has diverged significantly from the species used to build the HMM. Downy mildews have a narrow host range and pathogenicity-related proteins are likely to show high lineage-specificity due to co-evolution with their hosts. There is already evidence that downy mildew effectors show divergence from

the canonical RXLR motif [20,23,24], thus complementary approaches for effector prediction that utilize other conserved features, such as the WY domain, are necessary to fully characterize the repertoire. In addition, due to the importance of the WY domain in effector function [31–33], WY domain containing proteins may be better candidates for effectors than those containing only the RXLR motif.

To identify a more complete repertoire of candidate effectors in the reference genome of *B. lactucae* and to test whether the WY domain is informative for predicting effectors in the Peronosporales, we searched for this domain using an HMM built from sequences of the WY domain in three *Phytophthora* species [27]. This revealed additional effector candidates that had not been found using an RXLR-based search; similar results were also obtained for other downy mildews and well-studied *Phytophthora* species. These predicted WY proteins from *B. lactucae* had other signatures of oomycete effectors, such as presence of a secretion signal, N-terminal intrinsic disorder, lineage specificity, and expression during infection. A subset of the predicted WY effectors suppressed the host immune system, while others elicited programmed cell death in specific genotypes of lettuce, indicative of recognition by host resistance proteins. Therefore, searches for the WY domains are highly useful for identification of downy mildew effectors lacking the RXLR motif, which was previously considered canonical for effectors of the Peronosporales.

Results

Our HMM search initially identified 59 candidate WY effectors encoded by the gene models predicted in the *B. lactucae* SF5 assembly [40]; however, three pairs of

genes appeared to be allelic based on sequence similarity and read depth, leaving a total of 55 non-redundant genes encoding candidate effectors (Figure 1A; Supplemental Table 1). Signal peptides were predicted for 43 of these 55 proteins, of which two proteins had a predicted transmembrane helix outside of the signal peptide (Figure 1A). Several predicted WY proteins seemed to be missing their start codons due to N-terminal truncation when compared to close relatives. One of these predicted proteins, BLN06, was found to be missing a significant portion of the N-terminal sequence in SF5 compared to BL24, which was the source isolate for the cloning of *BLN06* reported in Pelgrom *et al*. [41].

The N-terminal sequences of the 55 predicted WY effectors were examined for the RXLR motif using both HMMs and string searches. One protein was predicted to have an RXLR motif by the HMM and an additional 10 proteins were identified by a string search for [RQGH]xLR or RXL[QKG], while 33 proteins were predicted to have an EER motif using a string search for [DE][DE][EK] (Figure 1A). To find divergent RXLR-like motifs in the WY effector candidates, we searched for a highly degenerate pattern based on mutational studies of the RXLR motif [35] and natural RXLR variants reported for other downy mildews [5–9]. This revealed an additional 38 proteins with an RXLR-like motif within the first 60 amino acids after the signal peptide matching the pattern [RKHGQ][X]{0,1}[LMYFIV][RNK], many of which also had an EER motif (Figure 1A) (Supplemental Table 1). Therefore, the majority of candidate WY effectors in *B. lactucae* have a non-canonical RXLR motif. In the C-terminal domain, the WY effector candidates had one to seven WY domains per protein, with a diversity of domain architectures (Figure 1). The WY domain from *B. lactucae* showed high

185 conservation of the characteristic conserved tryptophan (W) residue but appeared to
186 show equal preference for tyrosine (Y) or phenylalanine (F) for the second
187 characteristic residue of the domain (Fig. 1B). To investigate whether or not there are
188 WY effector candidates that are lacking the canonical RXLR motif in other oomycetes,
189 the predicted open reading frames (ORFs) from several published oomycete genomes
190 were surveyed for the RXLR motif and the WY domain. Approximately half of the WY
191 proteins predicted in seven downy mildew species lacked the RXLR motif; in six
192 *Phytophthora* spp., the majority of predicted WY proteins had RXLR motifs, but
193 between 9–21% of secreted WY proteins did not contain this motif (Fig. 2).
194 Consequently, the repertoire of candidate WY effectors in other oomycetes may be
195 heavily under-reported.

196 Intrinsic disorder had previously been reported to be a characteristic of the N-
197 terminus of oomycete effectors containing the RXLR motif [42]. Therefore, we
198 investigated whether the predicted degree of structural disorder was a characteristic
199 of candidate WY effectors lacking a canonical RXLR. The predicted levels of intrinsic
200 disorder were calculated for proteins containing RXLR motifs, for proteins containing
201 WY domains but no RXLR motif, as well as for the entire predicted secretome for
202 comparison. Proteins containing RXLR and/or WY domains had higher levels of
203 intrinsic disorder at their N-termini after the highly ordered signal peptide than the
204 entire set of secreted proteins (Fig. 3). Proteins containing a WY domain but lacking
205 a canonical RXLR motif had on average more disordered N-termini than effectors that
206 had RXLR but not a WY domain. The WY domain containing region had higher levels
207 of predicted structure than the RXLR-containing proteins that lacked a WY domain

and the secreted proteins as a whole (Fig. 3), consistent with the WY domains forming an α-helix bundled structure [27]. This predicted pattern of high intrinsic disorder at the N-terminus and high structure towards the C-terminus was consistently observed in all six downy mildews and six *Phytophthora* species analyzed (Suppl. Fig. 2). Therefore, a high level of intrinsic disorder is a consistent characteristic of the N-termini of oomycete effectors, regardless of whether they have a canonical RXLR motif; the functional significance of this remains to be investigated.

To evaluate lineage specificity of effectors due to co-evolution of pathogens with their hosts, we used BLAST to identify orthologs in other oomycete species. All of the 39 predicted secreted candidate WY effectors of *B. lactucae* had little sequence similarity to sequences in other genomes with the best BLASTP hit being only 46% identity with a protein from *P. infestans* (Fig. 4). Most of the proteins had best-hit identities between 20 to 30%, which is similar to the level of amino acid conservation between WY domains in different effectors [27].

A time-course RNA-seq experiment of lettuce seedlings infected with *B. lactucae* isolate SF5 was analyzed to investigate the expression of the WY effector candidates during infection. Expression was detected for all candidate WY encoding genes. The four mostly highly expressed WY containing effectors lacked a canonical RXLR motif (Fig. 5).

To test whether *B. lactucae* WY effectors were recognized by the host immune system, 21 randomly-selected WY effectors that differed in their number of WY domains were chosen to be screened against lettuce germplasm. Genes were cloned from amplified genomic DNA to attempt to capture both alleles of each effector from

231 the heterozygous isolate SF5 [40]. In order to capture additional allelic diversity,
232 some effectors were also cloned from the heterokaryotic isolate C82P24 [40]. Two
233 alleles were obtained for many effectors; in addition, chimeric sequences appeared to
234 be obtained for several genes. Clones of all unique sequences for each effector were
235 retained because they could be informative for dissecting the sequence basis of host
236 recognition. This resulted in multiple distinct clones (wildtype alleles plus chimeric
237 sequences) of some effectors.

238 We screened 215 different accessions of wild and cultivated lettuce (Suppl.
239 File 2) using *Agrobacterium*-mediated transient expression for the elicitation of cell
240 death for their reactions to clones representing the 21 WY candidate effectors. These
241 accessions collectively express the majority of the known *Dm* genes as well as new
242 resistance factors [36]. Eleven of the 21 WY effectors were recognized by one or more
243 accessions (Fig. 6). Alleles of the same effector showed similar reactions except for
244 three genes (Fig. 6). The truncated version of BLN06 cloned from SF5 did not trigger
245 cell death in LS102, NunDm17, or RYZ2146 (Suppl. Figure 3) in contrast to BLN06
246 cloned from BL24 [41], suggesting that the recognition of this effector by these
247 genotypes may be determined by the N-terminal region of the effector after the
248 secretion signal.

249 The lines ViAE and ViCQ, which have introgressions from the wild lettuce
250 species *L. virosa* [43], recognized five effectors: BLN08, BSW03, BSW04m, BSW04p,
251 and BSW14, as well as the chimeric sequence BSW04m/p (Fig. 6A). The *L. virosa*
252 accessions that were the resistance donors for ViAE and ViCQ also recognized these
253 five effectors, but not the chimeric sequence BSW04m/p (Fig. 6B). Many *L. sativa*

254 cultivars and a few genotypes of *L. saligna* and *L. serriola* were observed to have
255 necrosis or yellowing in response to the chimeric effector BSW04m/p, suggestive of
256 a non-specific reaction to this unnatural protein. Some of the genotypes that
257 recognized BSW04m/p also recognized BSW04p, but not the paralog BSW04m. Three
258 of these genotypes, Capitan, Ninja, and Femke, share the resistance gene *Dm11*;
259 therefore, we tested two additional cultivars, Fila and Mondian, which also contain
260 *Dm11* for recognition of BSW04p. These varieties also recognized BSW04m/p and
261 BSW04p, but not BSW04m. Due to recognition of BSW04p by multiple varieties that
262 contain *Dm11*, BSW04p is a candidate for the protein encoded by the *Avr11* gene.
263 BLN08, BSW03, BSW04m, and BSW14 are candidate avirulence proteins for which
264 cognate *Dm* genes have yet to be identified.

265 Bioinformatic prediction of subcellular localization using NucPred [44]
266 suggested that BSW04p had a C-terminal nuclear localization signal (score 0.79). To
267 investigate whether BSW04p was nuclear localized, N-terminal yellow fluorescent
268 protein (YFP) fusions were expressed in lettuce using *Agrobacterium*-mediated
269 transient assays. We also made N-terminal YFP fusions of two other effectors, BLN08
270 and BSW03, which lacked predicted nuclear localization signals. BSW04p was
271 localized to the nucleus as predicted, while BLN08 and BSW03 were localized to the
272 cytoplasm and/or periplasm (Fig. 7). Therefore, predictions of subcellular
273 localization were accurate for these three effectors and may indicate the cellular
274 location of their targets during infection.

275 We also tested candidate effectors for their ability to suppress PAMP-triggered
276 immunity (PTI). Twenty-one effectors were transiently expressed in *Nicotiana*

277 *benthamiana* and the level of reactive oxygen species (ROS) production induced by
278 flg22 was measured. Three effectors significantly suppressed ROS production to a
279 similar extent as two known bacterial suppressors of PTI (Fig. 8). The level of
280 induction of ROS by flg22 was significantly higher with some effectors; however,
281 there was no induction of ROS in the absence of flg22. Therefore, in this assay, at least
282 three effectors suppress PTI and some may actually increase PTI responsiveness.
283

284 **Discussion**

285 Effectors play a critical role in interactions between pathogens and their hosts.
286 Accurate prediction and annotation of effector repertoires is foundational for
287 functional genomics studies of pathogens. Due to their economic importance in
288 agriculture, an increasing number of *Phytophthora* and downy mildew pathogens are
289 being sequenced. Prior to this study, the majority of cloned avirulence genes have
290 encoded proteins with a RXLR motif [45]. This was not surprising considering that
291 most of these studies used the RXLR motif as their primary, or only, criterion to
292 identify candidate effectors. Our results demonstrate that there are many candidate
293 effectors containing the effector-related WY domain that lack the canonical RXLR
294 motif, especially in the downy mildews, but also in *Phytophthora* spp. In *B. lactucae,*
295 we have shown that these non-RXLR, WY domain containing effectors show
296 characteristics of RXLR effectors, such as N-terminal intrinsic disorder, lineage
297 specificity, and expression during infection. Furthermore, some of these proteins can
298 act as suppressors of the host immune system, while others trigger the hypersensitive
299 response in resistant host cultivars. Thus, despite lacking the canonical RXLR-motif,

300 these WY domain containing proteins have both virulence and avirulence activity.
301 Consequently, numerous candidate effector genes are likely to have been missed in
302 the genomic analysis of other species within the Peronosporales. Bioinformatics
303 pipelines for predicting effectors in both *Phytophthora* spp. and downy mildew
304 pathogens should include an HMM for the WY domain because it may be more
305 informative of function and result in fewer false positives than string searches for the
306 RXLR motif.

307 Many WY effectors were initially predicted to not have a signal peptide and
308 therefore not to be secreted; this could have been due to misannotation or reflect
309 biological reality. Several had a predicted signal peptide downstream of the ATG in
310 the gene model; these signal peptides started with a methionine, which was
311 supported as the correct start in manual curation using RNAseq data. Therefore,
312 studies that rely on the presence of a signal peptide when using predicted ORFs may
313 be missing true effectors with misannotated start codons. Some WY effectors had
314 clearly lost the signal peptide due to N-terminal deletion; this was observed by
315 comparisons within effector families. The truncated effectors are unlikely to be
316 functional because they are missing the secretion signal and would not therefore be
317 secreted from the cell. Signal peptide loss may be an evolutionary strategy for the
318 pathogen to evade recognition of effectors.

319 Although very few of the WY effectors from *B. lactucae* contained the canonical
320 RXLR motif, nearly all of them contained a degenerate RXLR motif. However, the
321 degenerate RXLR regular expression should not be used on its own to search for genes
322 encoding RXLR proteins due to the high false positive rate (>50%). Functional studies

323 are needed to ascertain which of these degenerate motifs can function similarly to the
324 canonical RXLR motif in protein secretion [15]. Despite lacking the canonical RXLR
325 motif, the WY effectors had other features similar to RXLR proteins such as high N-
326 terminal intrinsic disorder and the presence an EER motif. N-terminal intrinsic
327 disorder has been predicted for RXLR effectors of *Phytophthora* and is also a common
328 feature of bacterial effectors [46]. The biological significance of these features
329 remains to be studied, particularly whether these intrinsically disordered domains
330 are important in post-translational modification or protein-protein interactions as is
331 the case for intrinsically disordered regions in other organisms [47,48].

332 The number of WY domains per protein varied considerably, from one to
333 seven in *B. lactucae*. Many pathogen effectors exhibit rapid evolution and divergence
334 due to selective pressure of evolving host targets and host resistance proteins [25].
335 Duplication of domains may allow for evolution of novel effector functions or for
336 evasion of host recognition while retaining function [30]. Variation in the number of
337 repeated domains is reminiscent of NB-LRR proteins, which recognize effectors
338 (and/or effector activity) and also have leucine-rich repeated domains [49,50].
339 Duplication of regions encoding WY domains may have happened within a gene
340 through replication errors or between different genes through illegitimate
341 recombination. The genomic sequences of the repeats will be analyzed in multiple
342 isolates to reveal the origins of these duplications and domain expansion or
343 contraction.

344 Analysis of the amino acid sequences of the WY domain in *B. lactucae* showed
345 that it may be better considered as a W[Y/F] domain, due to the equal preference for

346 phenylalanine and tyrosine for the second characteristic residue. This substitution
347 has a BLOSUM score of 3, indicating that it is fairly common. Both tyrosine and
348 phenylalanine are aromatic amino acids; however, the hydroxyl group on tyrosine
349 makes it slightly bulkier, more polar, and introduces a potential phosphorylation site.
350 Variation in this region is not uncommon in other oomycete species: the fifth of the
351 seven domains in Psr2 of *P. sojae* has an F instead of a Y and is similar in structure to
352 the single domain of ATR1 in *H. arabidopsidis* that has a cysteine at the Y position [30].
353 Further structural characterization is needed to reveal whether these substitutions
354 alter protein structure and their biological function.

355 In oomycetes, WY domain containing effectors have been shown to have
356 several functions including PTI suppression [51]. At least three WY effectors from *B.*
357 *lactucae* were able to suppress the host immune system by interfering with pathogen-
358 triggered production of ROS. Suppression of host defenses is critical to the survival of
359 *B. lactucae* and therefore it is not surprising that multiple effectors target the basal
360 immune system. Identification of the host targets of these effectors will determine
361 which steps in the signal transduction cascade are modulated by each effector or may
362 reveal candidates for susceptibility genes in the host that are required for successful
363 proliferation of *B. lactucae*.

364 Effectors are powerful tools for the discovery and characterization of host
365 resistance genes [52]. Eleven of the *B. lactucae* effectors tested were recognized by
366 one or more lettuce lines. Their cognate R genes will be identified using mapping of
367 segregating $F_{2:3}$ and recombinant inbred line populations. Recognition of four *B.*
368 *lactucae* effectors (BLG01, BLN08, BLR31, and BLR38) has been successfully mapped

369 [23,41,53]. BLG01 and BLN08 have been shown to be recognized broadly by *L. saligna*
370 [23,53]. Our study confirms the results for BLNO8 and revealed BSW14 as an
371 additional effector recognized by *L. saligna*. BLN08 and BSW14 share little sequence
372 similarity (besides containing WY domains). Non-host resistance in *L. saligna* is
373 clearly complex [54], but these results show that it is mediated in part by recognition
374 of multiple effectors.

375 Not all RXLR candidate effectors have WY domains and the presence of a WY
376 domain is not required for the avirulence activity of all effectors; for example, the *B.*
377 *lactucae* effectors BLG01 and BLG03 do not contain WY domains, yet they elicit an
378 immune response in lettuce [23]. Structural elucidation of an RXLR effector lacking
379 the WY motif, *H. arabidopsidis* ATR13, revealed that it contained a helical fold that
380 was distinct from the WY fold [55]. It would be informative to determine and compare
381 the protein structures of additional RXLR effectors to determine whether there are
382 other conserved C-terminal domains that may be involved in effector function in a
383 similar way as the WY domain.

384 Both RXLR and WY effectors provide tools for monitoring pathogen
385 populations and effector-driven resistance breeding. Analysis of diverse, global
386 isolates will allow the characterization of individual effector repertoires as well as the
387 development of the pan-repertoire for a whole pathogen species. Effectors also will
388 be highly instrumental in cloning their cognate resistance genes as well as the
389 identification of effector targets in the host. In addition, screens for resistance using
390 transient expression of individual effectors will allow the pyramiding of resistance
391 genes with different specificities that will maximize the evolutionary hurdle for the

pathogen to become virulent. Ultimately, knowledge of effector repertoires will allow data-driven deployment of resistance genes leading to more durable disease resistance [56].

Materials and Methods

Effector prediction

To search for the WY domain, a Hidden Markov Model (HMM) was built using HMMer v3.1 [57] based on the inferred amino acid sequences of WY domains from *P. infestans*, *P. soja*e, and *P. ramorum.* These sequences were obtained from the supplemental material of Boutemy *et al*. [27] who predicted genes encoding WY domains based on motif searches of candidate RXLR effectors and identified a 49 amino acid long motif that spanned the WY domain in the crystal structures of Avr3a11 and PexRD2 [26]. Candidate WY effectors were predicted using this HMM to search translated predicted ORF sequences (>80 amino acids) as well as gene models in the draft genome of *B. lactucae* isolate SF5 [40]. Sequences with a positive HMM bit score were considered to be putative WY domain effectors as in [27]. Signal peptide prediction was performed on candidate WY effectors using SignalP v 4.1 [58] and PhobiusSP [59]. Default settings were altered for SignalP v 4.1 to have sensitivity similar to SignalP v 3.0. Output was compared between SignalP v 4.1 sensitive and the combination of SignalP4.0 + SignalP 3.0, and identical results were obtained from the two methods. Gene models were more accurate for predicting signal peptides than translated ORFs — in part due to misannotated start codons upstream of the probable

415 true start codon and signal peptides in the ORFs. However, on several occasions the
416 gene model was missing a signal peptide found in the ORF – these gene models were
417 manually updated to reflect this likely true start site. SignalP v 4.1 in sensitive mode
418 was better able to predict signal peptides in proteins with misannotated start codons
419 compared to SignalP v 4.0 or v 5.0.
420
421 *RXLR prediction*
422 A combination of string searches and HMMs were used to search for the RXLR motif
423 in oomycete predicted WY proteins. The following strings were used based on
424 variants observed in downy mildews: [RQGH]xLR or RXL[QKG] for RXLR and
425 [DE][DE][KR] for EER. The Whisson *et al*. HMM [14] was also tested, although this did
426 not reveal any more RXLR effector candidates. To search for additional non-canonical
427 RXLR motifs in WY candidates, a highly degenerate string of
428 [RKHGQ][X]{0,1}[LMYFIV][RNK] was used.
429
430 *Estimation of false positive rates for effector prediction*
431 We determined false positive rates for each motif by analyzing multiple permutations
432 of the non-redundant secretome using the same pipeline as described above for
433 effector prediction. At least ten random permutations of the sequence space were
434 created using the MEME fasta-shuffle-letters program (with a kmer size of 1) using
435 peptides starting after the cleavage site identified by SignalP v4.1. The false positive
436 rate for each motif was estimated as the average frequency of detection in the
437 permutated sequences divided by the observed frequency in the original sequences.

The estimated false positive rate for the RXLR and WY motif searches are given in Table 1.

Table 1. False positive rates for RXLR and WY HMM and string searches across 14 oomycete genomes

Motif	String/HMM	False Positive Rate (Average +SD)	Range
RXLR	RXLR	45.2% ± 3.4%	32-54%
RXLR	[RQGH]XLR or RXL[QKG]	56%± 2%	50–64%
RXLR	Whisson HMM [14]	1.5% ± 0.8%	0.1-3.3%
EER	[DE][DE][KR]	49.4% ± 2.6%	41-62%
RXLR-EER	RXLR + [DE][DE][KR]	9.4% ± 3.0%	4-16%
Degenerate RXLR	[RKHGQ][X]{0,1}[LMYFIV][RNK]	74%± 0.8%	71-77%
WY	Boutemy HMM [27]	0.05% ± 0.09%	0-0.3%

Intrinsic Disorder

PONDR VSL2 [60] was used to calculate levels of intrinsic disorder for groups of candidate effectors, grouped by the presence of an RXLR-like motif, EER-like motif, and/or WY domain. PONDR VSL2 is a meta-predictor of protein disorder that utilizes neural networks and amino acid context to give a weighted disorder score at each amino acid position. The average sequence disorder was calculated at each amino acid position in each group of effectors and aligned on the first amino acid. Plots were generated from the average positional disorder scores calculated from all peptides in a group. The entire non-redundant, predicted secretome was used as a reference for comparison.

Sequence comparison and determination of lineage specificity

To generate a neighbor-joining tree of the WY effector candidates, whole protein amino acid alignments were performed using MUSCLE 3.8.425 [61] implemented in Geneious 11.0.5 (http://www.geneious.com) with default settings. A UPGMA tree was built in Geneious with bootstrap resampling (100 replicates). The resulting tree was annotated using the Interactive Tree of Life [62] and stylistically refined in the GNU Image Manipulation Program (http://www.gimp.org). To build a sequence logo for the WY domain from *B. lactucae,* a multiple sequence alignment of WY domains was built using MUSCLE 3.8.425 [61], was manually corrected for alignment errors, and the sequence logo generated using Weblogo (http://weblogo.berkeley.edu/logo.cgi).

To determine if the candidate WY proteins are unique to *B. lactucae,* BLASTp [63] was used to search for orthologs in other oomycete species. BLASTp-based sequence comparisons with an e-value threshold of 0.01 were performed against the following oomycete genomes: *Albugo laibachii* [8], *H. arabidopsidis* [64], *P. capsici* [65], *P. infestans* [3], *Phytophthora parasitica* [66], *P. ramorum* [5], *P. sojae* [5], *Pythium ultimum* [7], *Saprolegnia parasitica* [67], *Pseudoperonospora cubensis* [21], *Plasmopara halstedii* [24], *Plasmopara viticola* JL-7-2 [68], INRA-PV221 [69], *Peronospora tabacina* [70], and *Peronospora effusa* [71].

RNA-seq analysis

Messenger RNA was isolated from cotyledons of lettuce cv. Cobham Green infected with isolate SF5 of *B. lactucae* with Dynabeads™ mRNA DIRECT™

Purification kit (Thermo Fisher Scientific, Waltham, MA) per manufacturer recommendations for plant tissue. Library construction was done following the protocol of Zhong *et al*. [72]. The resulting libraries were sequenced in single-end mode in a HiSeq 3000 at the UC Davis DNA Technologies Core (http://dnatech.genomecenter.ucdavis.edu/). The quality of the libraries was assessed using FastQC V0.11.2 [73]. Bacterial and human contaminants were filtered with BWA-MEM [74] mapping against custom references of microbial and human databases. The remaining reads were mapped to a joint reference made up of the *L. sativa* cv. Salinas (GenBank: GCF_002870075.1) and *B. lactucae* isolate SF5 (GenBank: GCA_004359215.1) reference assemblies using STAR v2.6.0 [75]. STAR was run with the options "--sjdbOverhang 99 --sjdbGTFtagExonParentGene Parent --quantMode GeneCounts". The strand specific read counts for each replicate were calculated from the reads per gene table output by STAR. Reads counts were normalized for gene length by dividing the read counts by the length of the gene it was mapped to (Reads Per Kilobase: RPK). The total RPK of the *B. lactucae* portion of each replicate was calculated and used to divide the RPK to calculate the transcripts per million (TPM) for each gene. A subset of the genes that encode putative WY domains were taken from this total, the average TPM for three replicates of each time point was calculated (excluding replicate 2 at 72 hours, due to low coverage) and the log10(1+average TPM) was calculated for each time point. These values were plotted using Heatmap2 [76] from the package gplots, clustering of putative effectors by expression was performed with hclust [77].

501 *Gateway cloning*

502 Effector candidates without their signal peptide were cloned into the
503 pEarleyGate100 (pEG100) vector for plant expression [78] using Gateway cloning
504 (Thermo Fisher Scientific). Candidate effector genes were amplified from genomic
505 DNA isolated from spores of *B. lactucae* isolate SF5 or C82P24 using Phusion High
506 Fidelity Polymerase (Thermo Fisher Scientific) and primers (Suppl. File 3) that
507 amplified each ORF after the predicted signal peptide cleavage site. The Kozak
508 sequence (ACCATG) was added to the forward primer for correct translational
509 initiation. PCR products were purified using polyethylene glycol (PEG) precipitation
510 to remove primers and primer-dimers, recombined into pDONR207 using BP Clonase
511 II (Thermo Fisher Scientific), and transformed into chemically competent *Escherichia*
512 *coli* DH10B cells. The resulting entry clones were sequenced using primers designed
513 to pDONR207 to confirm gene identity and identify alleles. The entry clones were
514 then recombined into pEG100 using LR Clonase II and transformed into *E. coli* to
515 generate expression clones. The expression clones were then transformed into
516 *Agrobacterium tumefaciens* strain C58rif$^+$ using electroporation. Kanamycin-resistant
517 colonies were confirmed for the transgene using gene-specific primers.

518

519 *Agrobacterium-mediated transient assays*

520 Agroinfiltration and transient expression experiments were performed using
521 conditions optimized for lettuce [79]. *A. tumefaciens* was grown overnight from
522 glycerol stocks and resuspended in 10 mM $MgCl_2$ to OD=0.3–0.5. The youngest fully
523 expanded leaves of 3 to 4-week-old greenhouse grown lettuce plants were infiltrated

524 with the *A. tumefaciens* cultures using a needless syringe. Leaves were examined four
525 to five days post-infiltration for signs of macroscopic cell death, indicative of immune
526 recognition by host resistance proteins. *A. tumefaciens* containing pEG100 empty
527 vector or pEG100:GFP were used as negative controls; *A. tumefaciens* containing T-
528 DNAs that expressed HopM1 or AvrPto, which are *Pseudomonas syringae* effectors
529 known to elicit cell death in lettuce [80], were used as positive controls. To control
530 for false negatives, leaves that did not show cell death in response to the positive
531 control HopM1 were excluded from the analysis. To control for false positives, leaves
532 that showed cell death in response to the empty vector or GFP control were also
533 excluded from the analysis. In addition, any cell death observed in the initial
534 screening was confirmed by repeating infiltrations on at least four plants for effectors
535 found to cause cell death.
536
537 *Subcellular localization prediction and characterization*
538 Nuclear localization was predicted using NucPred [44] and nuclear
539 localization motifs predicted using LOCALIZER [81]. For localization experiments,
540 effectors were cloned without their signal peptide into pEG104 [31] as described
541 above resulting in an N-terminal YFP fusion. Three to five days post-Agroinfiltration,
542 lettuce leaves expressing N-terminal YFP fusions of effectors were examined for
543 subcellular localization. Nuclear staining was performed by incubating cut leaf tissue
544 in 18 nM DAPI in water for at least five minutes. Imaging was performed on a Zeiss
545 LSM 710 laser scanning confocal microscope with a 40x objective lens.
546

547 *PTI suppression assay*

548 Effectors were expressed in five-week-old plants of *N. benthamiana* using
549 Agroinfiltration as described above. Two days post-infiltration, two leaf discs (3.8
550 mm) were taken from each infiltration site away from the leaf veins using a cork
551 borer. Leaf discs were floated abaxial side up in 200 µL of distilled water in a 96-well
552 white assay plate and incubated at room temperature for 24 hrs. To measure
553 suppression of ROS production [82], the water was removed and 100 µL of assay
554 solution was added to the leaf discs, which contained 17 µg/mL luminol (Sigma-
555 Aldrich, St Louis, MO) and 10 µg/mL horseradish peroxidase type 6A (Sigma-Aldrich).
556 One of the two paired leaf discs was exposed to 100 nM of flg22 peptide (flg+) and the
557 other was not exposed to any elicitor as a control for endogenous ROS production.
558 The known bacterial suppressors of PTI, HopS2, and HopX1 [83], were used as
559 positive controls for suppression of ROS production; GFP was used as the negative
560 control. Luminescence was measured on a FilterMax F5 Plate Reader (Molecular
561 Devices, San Jose, CA) promptly after adding in the assay solution and was measured
562 every two minutes for a total of 42 minutes. Each assay was replicated sixteen times.
563

564 **Acknowledgements**

565 We thank Keri Cavanaugh, Alyssa Schweickert, Dasan Gann, Catherine Lopez, Amber
566 Robbins, Natalie Hamada, Pauline Sanders, and Sebastian Reyes Chin Wo (all UC
567 Davis) for wet lab and computational assistance. We thank Gitta Coaker (UC Davis)
568 for assistance with the ROS assay. We thank Brigitte Maisonneuve (INRA, Montfavet,
569 France) for providing the FrRsal-1, ViAE, and ViCQ lines of lettuce and Ales Lebeda

(Palacký University, Olomouc, Czech Republic) and Alex Beharav (The Hebrew University, Tel Aviv, Israel) for lines of *L. saligna*. We thank Lien Bertier, Dasan Gann, Anne Giesbers, and Elizabeth Georgian for helpful comments on earlier versions of this manuscript. The work was supported by an NSF Graduate Fellowship and a USDA Fellowship #2018-67011-28053 to KW and the NSF/USDA AFRI Microbial Sequencing Program award #2009-65109-05925 to RWM.

Author Contributions

KW, JG, MP, and RWM conceived and designed the experiments. KW, JG, TK, MN, AP, AG, JK, and KL performed the experiments. KW, JG, KF, TK, MN, AP, AG, JK, and KL analyzed the data. KW, JG, and RWM wrote the paper. All authors approved the final submission.

Data sources

The reference genome assembly of *B. lactucae* is available from NCBI, GenBank ID: GCA_004359215.1. RNAseq reads of lettuce cv. Cobham Green infected with *B. lactucae* isolate SF5 is available at NCBI SRA BioProject PRJNA523226. Sequences of effector proteins are available in Supplementary data. The all data for interactions between effectors and individual lines of *Lactuca* spp. are available at http://bremia.ucdavis.edu/BIL/BIL_interaction.php.

Figure legends

Figure 1. WY effector candidates from *B. lactucae* isolate SF5. (A) UPGMA consensus tree of the 59 predicted WY effectors from *B. lactucae* isolate SF5 based on whole protein amino acid sequence alignment using MUSCLE. Sequences that appear to be allelic are indicated with asterisks next to the sequence name. Bootstrap values and branch lengths are given for closely related proteins. Signal peptides are shown as circles (red circle for SP; white circle for no SP). RXLR motifs are shown as triangles (black triangle for RXLR ([RQGH]xLR or RXL[QKG]); grey triangle for degenerate RXLR ([RKHGQ][X]{0,1}[LMYFIV][RNK]), white triangle for no RXLR-like sequence) followed by an inverted triangle for EER motifs (yellow triangle for [DE][DE][RK], white triangle for no EER-like sequence). WY domain architecture is shown using blue rectangles, with a black line representing the total length of the protein and rectangle position representing the location of the WY motif as predicted by HMMer 3.0. (B) Sequence logo for the WY domain from *B. lactucae* built from a multiple sequence alignment of WY domains predicted by HMMer 3.0.

Figure 2. Distribution of predicted secreted WY effectors with or without RXLR and/or EER motifs in the genomes of downy mildew pathogens and *Phytophthora* species. HMMer was used to search predicted secretomes for each species for the WY domain. For the WY domaining containing proteins, the presence

911 of RXLR and EER were determined by searching for [RQGH]XLR or RXL[QKG] within
912 the first 60 amino acids after the signal peptide and [DE][DE][KR] within the first
913 100 amino acids after the signal peptide. For the non-WY domain containing
914 proteins, the RXLR and EER was determined by searching for a strict "RXLR" with
915 [DE][DE][KR], within the first 60 and 100 amino acids, respectively, plus proteins
916 found by searching for the RXLR-EER domain using the RXLR-EER HMM from [14].
917
918 **Figure 3. Intrinsic disorder in the first 150 N-terminal amino acid sequences**
919 **of RXLR and/or WY containing candidate effectors in *B. lactucae*.** Proteins were
920 categorized as WY with no RXLR (yellow), WYs with RXLR (black), RXLR+EER (with
921 or without WY, purple), and the total predicted secretome (blue). RXLR and EER
922 motifs were as described in Fig 2. Average positional disorder scores [42] with
923 standard error are shown for each group of proteins.
924
925 **Figure 4. Lineage specificity of *B. lactucae* candidate secreted WY effectors.**
926 Secreted WY proteins predicted in isolate SF5 of *B. lactucae* were used as a query for
927 BLASTp against other oomycete translated ORFs. Isolate C82P24 was queried for *B.*
928 *lactucae.* The best BLAST hit percent identity for each protein was calculated. The
929 box plot shows the distribution of the best BLAST hits per *B. lactucae* WY protein
930 from each species, with each dot representing an individual data point. No hits were
931 observed to *Albugo laibachii, Saprolegnia parasitica,* or *Pythium ultimum.*
932

933 **Figure 5. RNA-seq expression levels during infection for the *B. lactucae* WY**
934 **effector candidates.** The transcripts per million (TPM) of each WY-encoding gene
935 was normalized by the total number of reads per kilobase assigned to *B. lactucae*
936 from RNAseq analysis of infected cotyledons over a seven-day time-course. This
937 value was log10(+1) transformed to enable visualization. The four highest
938 expressed WY encoding genes do not have recognizable RxLR translocation
939 associated motifs.

940

941 **Figure 6. Results of the screen for recognition of *B. lactucae* WY effector by**
942 **diverse genotypes of lettuce.** Candidate effectors were expressed in lettuce leaves
943 using Agroinfiltration and leaves were scored for their reaction four to seven days
944 post-infiltration. Qualitative scores were converted into numeric scores for data
945 analysis: 0 = no reaction (green), 1 = mild chlorosis (blue-green), 2 = chlorosis
946 (yellow), 3 = mild necrosis or mixture of chlorosis and necrosis (pink), and 4 = full
947 necrosis (magenta). The figure shows average scores for each effector on each
948 genotype; only accessions and effectors that had a necrotic or chlorotic response are
949 shown. Scores for all accessions screened and sample sizes can be found at
950 http://bremia.ucdavis.edu/BIL/BIL_interaction.php. Two groups of 28 and 11
951 accessions of *L. saligna* that had identical reactions are shown together; the
952 individual accessions making up each group are shown in Supplementary Table 2.

953

954 **Figure 7. Example Agroinfiltration results of reactions of *L. sativa* ViAE and**

955 **ViCQ and their progenitor R gene donors *L. virosa* LS238 and LS241 to several**
956 ***B. lactucae* effectors.** Photos are representative of a typical leaf. *B. lactucae*
957 candidate effectors either elicited necrosis (brown areas) indicative of an immune
958 recognition response (magenta text) or did not elicit a response (aqua text). GFP
959 and HopM1 were used as negative and positive controls for necrosis, respectively.
960 Leaves were collected five days post-infiltration and the first column for each
961 accession shows the uncleared leaf tissue; the second column shows leaf tissue
962 cleared in ethanol.

963

964 **Figure 8. Subcellular localization of three *B. lactucae* WY effectors in lettuce.**
965 Confocal images of lettuce expressing YFP fusion proteins. For YFP-SW4, split
966 images of (A) DAPI, (B) Chloroplast autofluorescence, (C) YFP, and (D) Merged show
967 nuclear localization. For YFP-SW1 (E) and YFP-SW3 (F), merged images of DAPI
968 (blue), chlorophyll autofluorescence (red), and YFP (yellow) show cytoplasmic or
969 periplasmic localization.

970

971

972 **Figure 9. Effect of *B. lactucae* candidate WY effectors on flg22-triggered**
973 **immune response.** Luminescence plots measuring effect of candidate effectors on
974 flg22-triggered PTI induction in *N. benthamiana* leaf discs. (A) Luminescence
975 averaged across biological replicates (14–24 reps each) for each effector over time.
976 (B) Bar plots of the average area under the curve (AUC) for luminescence over 40

977 minutes for each effector (N=14–24), with flg22 (red) or without flg22 (aqua).

978 Asterisks indicate averages in the flg22+ condition that are statistically different

979 from the average of GFP in the flg22+ condition (t-test, $p < 0.05$).

980

981 List of Supplemental Materials:

982 **Supplemental Table 1.** RXLR-like sequences observed within 100 amino acids of
983 the N-terminus of *B. lactucae* WY proteins, sorted by first amino acid.
984
985 **Supplemental Figure 1.** The number of RXLR-like motifs detected in the first 100
986 amino acids of the N-terminus of *B. lactucae* WY effectors.
987
988 **Supplemental Figure 2.** Intrinsic disorder of first 150 amino acids of RXLR and WY
989 containing candidate effectors mined from other oomycete genomes.
990
991 **Supplemental Figure 3.** Agroinfiltration results from BLN06-SF5 and sequence
992 comparison between BLN06 between SF5 and BL24.
993
994 **Supplemental File 1.** Sequences and NCBI reference numbers of the 59 WY
995 proteins predicted from the *B. lactucae* SF5 genome assembly.
996
997 **Supplemental File 2.** Lettuce genotypes tested for recognition of *B. lactucae*
998 effectors.
999
1000 **Supplemental File 3.** Primers used in Gateway Cloning of the *B. lactucae* effectors.

Figure 6. Results of the screen for recognition of *B. lactucae* WY effector by diverse genotypes of lettuce.

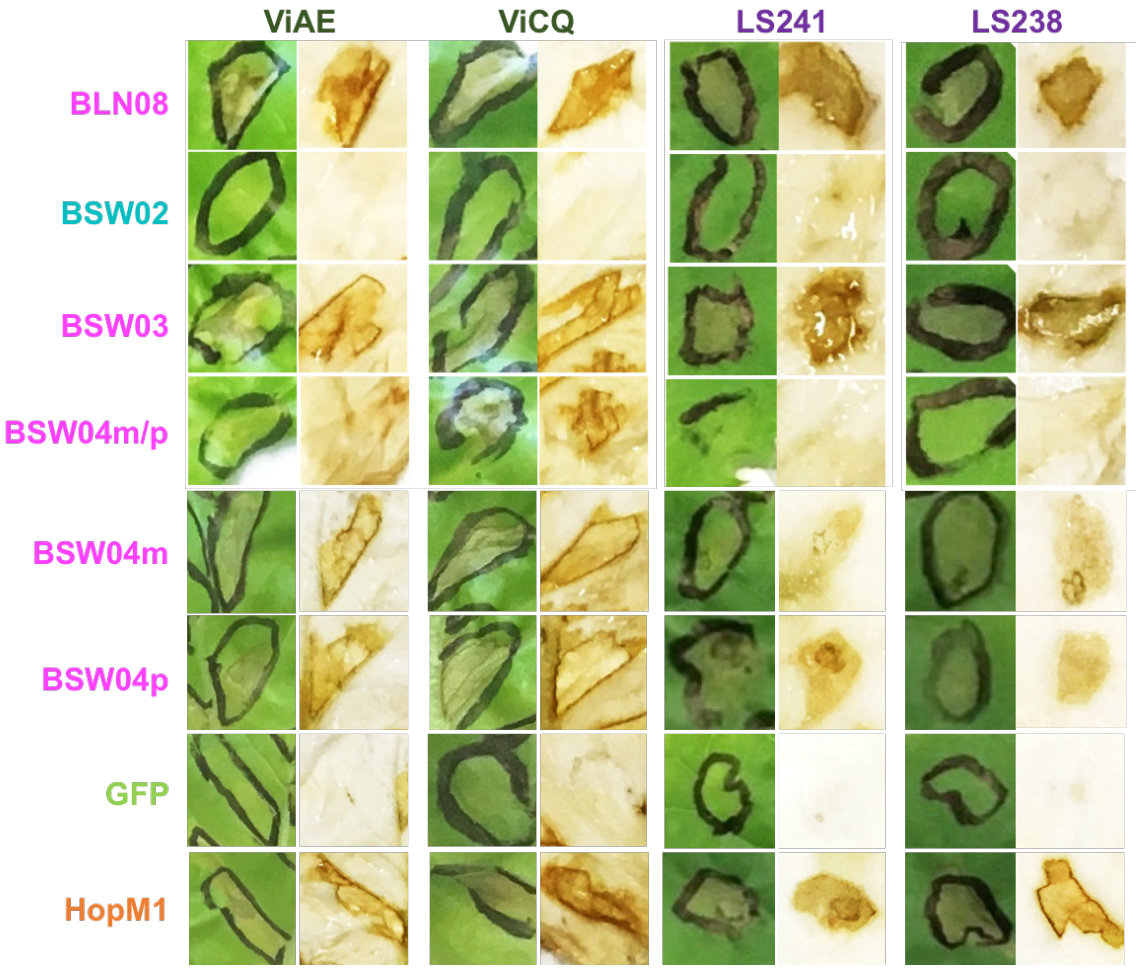

Figure 7. Example Agroinfiltration results of reactions of *L. sativa* ViAE and ViCQ and their respective progenitor R gene donors *L. virosa* LS241 and LS238 to several *B. lactucae* effectors.

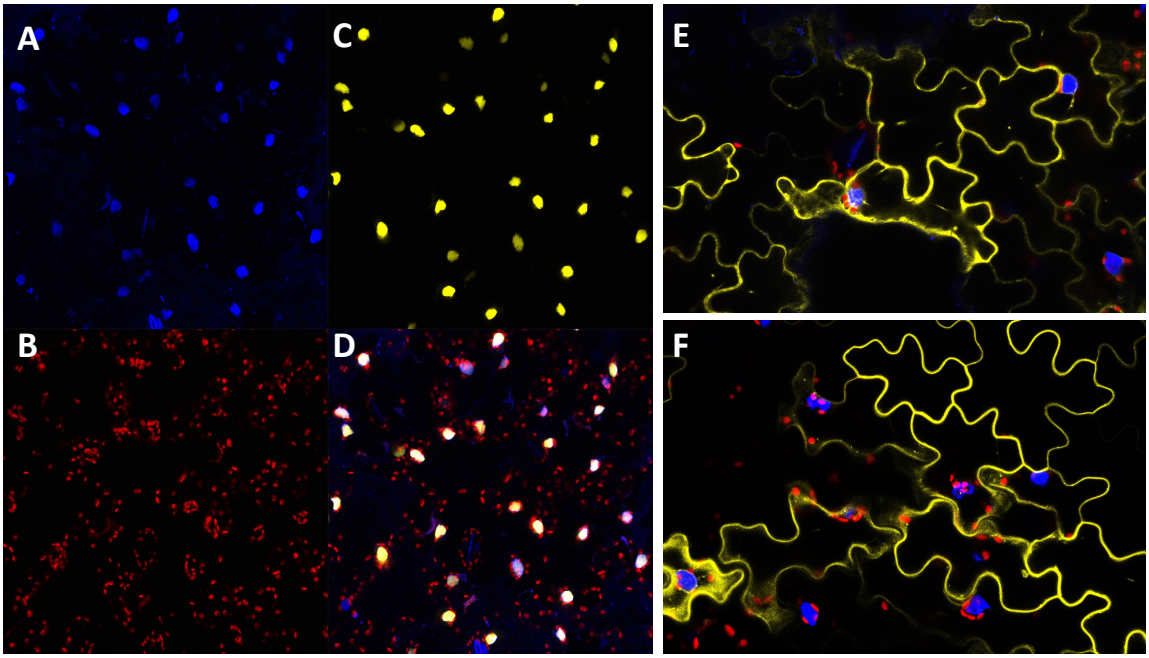

Figure 8. Subcellular localization of three *B. lactucae* WY effectors in lettuce.

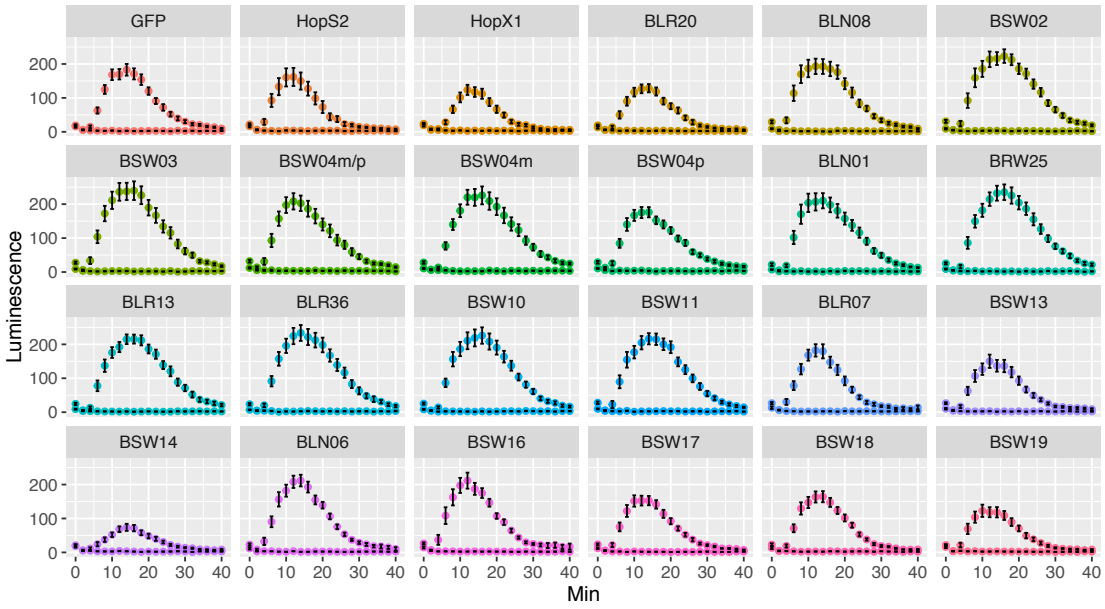

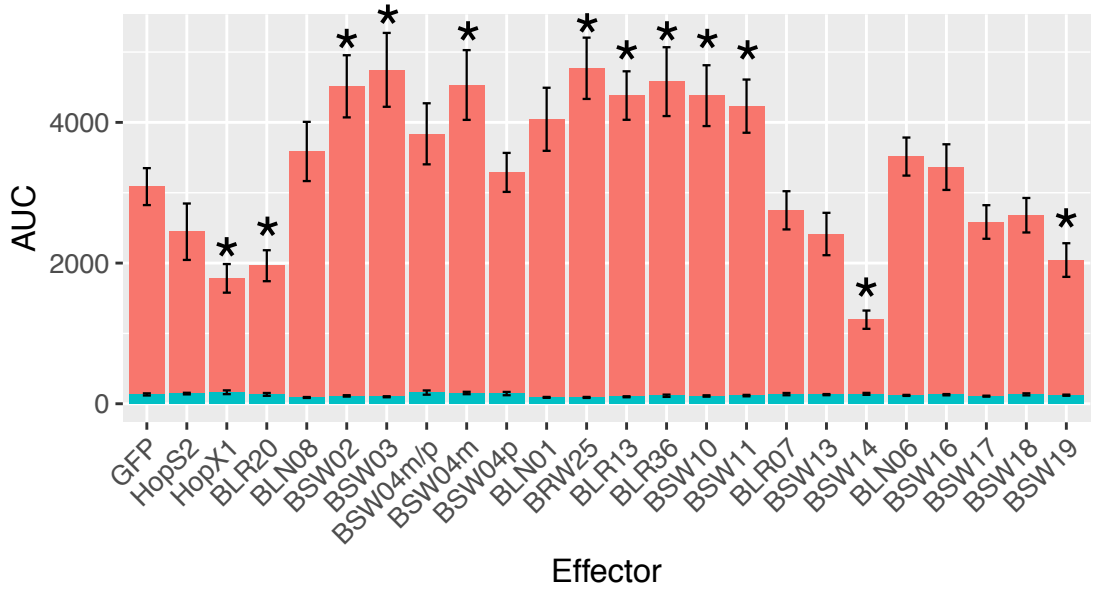

Figure 9. Effect of *B. lactucae* candidate WY effectors on flg22-triggered immune response.
