## Abstract

**Background:** Identifying effective candidate drug compounds in patients with neurological disorders based on gene expression data is of great importance to the neurology field. By identifying effective candidate drugs to a given neurological disorder, neurologists would (1) reduce the time searching for effective treatments; and (2) gain additional useful information that leads to a better treatment outcome. Although there are many strategies to screen drug candidate in pre-clinical stage, it is not easy to check if candidate drug compounds can be also effective to human.

**Objective:** We tried to propose a strategy to screen genes whose expression is altered in model animal experiments to be compared with gene expressed differentially with drug treatment to human cell lines.

**Methods:** Recently proposed tensor decomposition (TD) based unsupervised feature extraction (FE) is applied to single cell (sc) RNA-seq experiments of Alzheimer's disease model animal mouse brain.

**Results:** Four hundreds and one genes are screened as those differentially expressed during  $A\beta$  accumulation as age progresses. These genes are significantly overlapped with those expressed differentially with the known drug treatments for three independent data sets: LINCS, DrugMatrix and GEO.

**Conclusion:** Our strategy, application of TD based unsupervised FE, is useful one to screen drug candidate compounds using scRNA-seq data set.

## 1 Introduction

Drug discovery for neurological disorder has never been successful in spite of massive efforts spent [1]. One possible reason is because we generally do not

28 have suitable model animals for human neurological disorder [2]. Although a  
29 huge number of compounds are screened using model animals, only a few of  
30 them passed the human level screening. In this sense, it is required to screen  
31 candidate compounds using information retrieved from human at the earliest  
32 stage. One possible strategy to do this is the usage of human cell lines; Nev-  
33 ertheless, it is also not easy to perform, since generating cell line from human  
34 neurological disorder patients is not easy. In contrast to the cancer cell lines,  
35 which can be easily generated by immortalizing tumor cells, neuronal cells are  
36 hardly converted to cell lines, since mature neurons do not undergo cell divi-  
37 sion [3]. Therefore, it is difficult to test if candidate drugs work for human  
38 during pre-clinical stages.

39 In order to overcome this difficulty, we proposed an alternative strategy; com-  
40 paring disease gene expression with that of compound treated animals and/or  
41 human cell lines. Generally, compound screening is based upon phenotype; i.e.,  
42 evaluation of compounds efficiency is tested based upon if drug treatment can  
43 produce symptomatic improvement. Nevertheless, since it has been recently  
44 found that various neurological disorders share gene expression [4], focusing on  
45 gene expression profiles might be more reasonable. Following this strategy, we  
46 considered gene expression profiles (single cell RNA-seq) of mouse brain during  
47 amyloid  $\beta$  accumulation. As being aged, some set of gene expression progresses  
48 and significantly overlaps with genes that express differential expression caused  
49 by various compounds treatment. Since top ranked (i.e., with the most overlaps)  
50 detected compounds turn out to be tested previously toward Alzheimer disease  
51 (AD) treatment, lower ranked compounds also might be promising candidate  
52 compounds for AD.

## 53 2 Materials and Methods

### 54 2.1 Single cell RNA-seq

55 Single cell (sc) RNA-seq used in this study was downloaded from gene expression  
56 omnibus (GEO) using GEO ID GSE127892. It is composed of two genotypes  
57 (APP\_NL-F-G and C57Bl/6), two tissues (Cortex and Hippocampus), four ages  
58 (3, 6, 12, and 21 weeks), two sex (male and female) and four 96 well plates.  
59 For each of combined combinations, four 96 well plates, each of wells includes  
60 one cell, were tested. Among those wells tested, wells with insufficient gene  
61 expression were discarded. As a result, among  $2$  (genotype)  $\times$   $2$  (tissues)  $\times$   
62  $4$  (ages)  $\times$   $2$  (sex)  $\times$   $4$  (plates)  $\times$   $96$  (wells) = 12288 cells measured, scRNA-seq  
63 for only 10801 cells were provided.

### 64 2.2 Tensor decomposition based unsupervised feature ex- 65 traction

66 We applied recently proposed tensor decomposition (TD) based unsupervised  
67 feature extraction (FE) [5–14] to scRNA-seq. A tensor  $x_{j_1 j_2 j_3 j_4 j_5 j_6 i} \in \mathbb{R}^{96 \times 2 \times 2 \times 4 \times 2 \times 4 \times 29341}$

68 that represents gene expression of  $i$ th gene of  $j_1$ th cell (well) at  $j_2$ th genotype  
 69 ( $j_2 = 1$ :APP\_NL-F-G and  $j_2 = 2$ : C57Bl/6),  $j_3$ th tissue ( $j_3 = 1$ :Cortex and  
 70  $j_3 = 2$ :Hippocampus),  $j_4$ th age ( $j_4 = 1$ : three weeks,  $j_4 = 2$ : six weeks,  $j_4 = 3$ :  
 71 twelve weeks, and  $j_4 = 4$ : twenty one weeks),  $j_5$ th sex ( $j_5 = 1$ :female and  
 72  $j_5 = 2$ :male) and  $j_6$ th plate.

73  $x_{j_1 j_2 j_3 j_4 j_5 j_6 i}$  is standardized such that  $\sum_{i=1}^{29341} x_{j_1 j_2 j_3 j_4 j_5 j_6 i} = 0$  and  $\sum_{i=1}^{29341} x_{j_1 j_2 j_3 j_4 j_5 j_6 i}^2 =$   
 74 29341. HOSVD [5] was applied to  $x_{j_1 j_2 j_3 j_4 j_5 j_6 i}$  such that

$$x_{j_1 j_2 j_3 j_4 j_5 j_6 i} = \sum_{\ell_1=1}^{96} \sum_{\ell_2=1}^2 \sum_{\ell_3=1}^2 \sum_{\ell_4=1}^4 \sum_{\ell_5=1}^2 \sum_{\ell_6=1}^4 \sum_{\ell_7=1}^{29341} G(\ell_1, \ell_2, \ell_3, \ell_4, \ell_5, \ell_6, \ell_7) u_{\ell_1 j_1} u_{\ell_2 j_2} u_{\ell_3 j_3} u_{\ell_4 j_4} u_{\ell_5 j_5} u_{\ell_6 j_6} u_{\ell_7 i} \quad (1)$$

75 where  $G(\ell_1, \ell_2, \ell_3, \ell_4, \ell_5, \ell_6, \ell_7) \in \mathbb{R}^{96 \times 2 \times 2 \times 4 \times 2 \times 4 \times 29341}$  is core tensor,  $u_{\ell_1 j_1} \in$   
 76  $\mathbb{R}^{96 \times 96}$ ,  $u_{\ell_2 j_2} \in \mathbb{R}^{2 \times 2}$ ,  $u_{\ell_3 j_3} \in \mathbb{R}^{2 \times 2}$ ,  $u_{\ell_4 j_4} \in \mathbb{R}^{4 \times 4}$ ,  $u_{\ell_5 j_5} \in \mathbb{R}^{2 \times 2}$ ,  $u_{\ell_6 j_6} \in \mathbb{R}^{4 \times 4}$   
 77 and  $u_{\ell_7 i} \in \mathbb{R}^{29341 \times 29341}$  are singular value matrices that are orthogonal matrices.  
 78 In order to save time to compute, only  $1 \leq \ell_1, \ell_7 \leq 10$  were computed.

79 After investigation of  $u_{\ell_4 j_4}$ ,  $u_{2 j_4}$  represent monotonic dependence upon age  
 80 while  $\ell_1, \ell_2, \ell_3, \ell_5, \ell_6 = 1$  represent independence of cells, genotype, tissue,  
 81 sex and plate. Since  $G(1, 1, 1, 2, 1, 1, 2)$  has the largest absolute vales among  
 82  $G(1, 1, 1, 2, 1, 1, \ell_7)$ ,  $u_{2, i}$  is employed to compute  $P$ -values attributed to  $i$ th gene  
 83 as

$$P_i = P_{\chi^2} \left[ > \left( \frac{u_{2i}}{\sigma} \right)^2 \right] \quad (2)$$

84 where  $P_{\chi^2}[> x]$  is the cumulative probability of  $\chi^2$  distribution when the argu-  
 85 ment is larger than  $x$  and  $\sigma$  is the standard deviation.

86  $P$ -values are corrected by Benjamini and Hochberg criterion [15] and genes  
 87 associated with corrected  $P$ -values less than 0.01 are selected for downstream  
 88 analysis.

### 89 2.3 Enrichment analysis

90 Four hundreds and one genes selected by TD based unsupervised FE were up-  
 91 loaded to Enrichr [16] for enrichment analysis. Full list of enrichment analysis  
 92 as well as list of 401 genes are accessible at

93 <https://amp.pharm.mssm.edu/Enrichr3/enrich?dataset=5bbbe5602715daf9787895cd16829707>

94 List of 401 genes and three enrichment analyses used in this study, “LINCS  
 95 L1000 Chem Pert up”, “DrugMatrx” and “Drug Perturbations from GEO up”  
 96 are also available as supplementary material.

## 97 3 Results

98 When selecting genes using TD based unsupervised FE, we first need to specify  
 99 what kind of properties of gene expression we consider. In this study, we require  
 100 the followings.

- 101 1. Gene expression should be independent of cells within the same 96 wells  
102 plate.
- 103 2. Gene expression should be independent of genotype.
- 104 3. Gene expression should be independent of tissues.
- 105 4. Gene expression should have monotonic dependence upon age.
- 106 5. Gene expression should be independent of sex.
- 107 6. Gene expression should be independent of each of four 96 wells plates  
108 under the same conditions.

109 In other words, we try to select genes with the most robust monotonic age  
110 dependence as much as possible. The reason of this motivation is as follows.  
111 In the paper where data set analyzed here was investigated originally, Frigerio  
112 et al. [17] found that age is the primary factor of the microglia response to  
113 accumulation of A $\beta$  plaques. We found that singular value vectors with  $\ell_1 =$   
114  $\ell_2 = \ell_3 = \ell_5 = \ell_6 = 1$  represent independence of cells, genotypes, tissues, sex  
115 and plates (Figure 1 (A), (B), (C), (E), (F)). On the other hand,  $u_{2j_4}$  represents  
116 monotonic dependence upon ages,  $1 \leq j_4 \leq 4$  (Figure 1 (D)).

117 Next, we need to find the  $G(1, 1, 1, 2, 1, 1, \ell_7)$  with the largest absolute value  
118 in order to identify singular value vector,  $u_{\ell_7 i}$ , attributed to genes. Then we  
119 found that  $G(1, 1, 1, 2, 1, 1, 2)$  has the largest absolute value. Therefore, we  
120 decided to use  $u_{2i}$  for attributing  $P$ -values to genes as shown in eq. (2). Finally,  
121 401 genes are identified as being associated with adjusted  $P$ -values less than 0.01  
122 (The list of genes is available as supplementary material).

123 These 401 genes are uploaded to Enrichr to identify the compounds, with  
124 which genes expressing differential expression of cell lines treated are maximally  
125 overlapped with these 401 genes. As for “LINCS L1000 Chem Pert up” category  
126 (Table 1, full list is available as supplementary material), the top ranked  
127 compound is alvocidib, which was previously tested for AD [18]; there are also  
128 65 experiments (see supplementary material) of cell lines treated with alvocidib  
129 and associated with adjusted  $P$ -value less than 0.05. The second top ranked  
130 compound is AZD-8055, which was also previously tested for AD [19]; there  
131 are also 6 experiments (see supplementary material) of cell lines treated with  
132 AZD-8055 and associated with adjusted  $P$ -value less than 0.05.

133 One might wonder if this is an accidental agreement which is specific to  
134 LINCS data set. In order to confirm that it is not an accidental agreement, we  
135 also see DrugMatrix category (Table 2, full list is available as supplementary  
136 material). The top, fifth and tenth ranked compound is cyclosporin-A, which  
137 was also previously tested for AD [20]; there are also 57 experiments (see supple-  
138 mentary material) of cell lines treated with cyclosporin-A and associated with  
139 adjusted  $P$ -value less than 0.05. Finally, we tested “Drug Perturbations from  
140 GEO up” category in Enrichr (Table 3, full list is available as supplementary  
141 material). The top ranked compounds is imatinib, which was also previously  
142 tested for AD [21]; there are also 18 experiments (see supplementary material) of

143 cell lines treated with imatinib and associated with adjusted  $P$ -value less than  
144 0.05.

145 These findings suggest that our strategy is effective to find compounds that  
146 can be used for AD treatment. Thus, it might be worthwhile investigating lower  
147 ranked compounds in Tables 1, 2 and 3 as candidate compounds for AD, even  
148 if they were not known drugs for AD.

## 149 4 Discussion

150 First of all, since these cell lines in Table 1 are originated in human, our strategy  
151 can provide us the opportunity to check if proposed candidate drugs screened  
152 with model animals are also effective in human.

153 It is also remarkable that we do not need gene expression of all genes, but  
154 only a subset of genes (please remember that LINCS project measures only gene  
155 expression of less than one thousand genes) in order to predict candidate drugs  
156 with high accuracy. This might reduce the amount of money to screen numerous  
157 number of compounds.

158 Our method is also applicable to scRNA-seq in order to screen drug com-  
159 pounds candidate from scRNA-seq. To our knowledge, there are very limited  
160 number of studies that relate scRNA-seq to drug design [22,23], since scRNA-seq  
161 usually lacks cell labeling which is useful to screen differentially expressed genes.  
162 In this study, we simply make use of ages, which is not always directly related to  
163 diseases. In spite of that, drug we listed was correct, i.e., they are known drugs  
164 to some extent. Therefore, our strategy is also useful to add an alternative one  
165 along this direction, i.e., making use of scRNA-seq for drug design.

166 Thus, our strategy, TD based unsupervised FE, might be promising method-  
167 ology to screen drug candidate compounds.

## 168 5 Conclusion

169 In this paper, we applied TD based unsupervised FE to scRNA-seq taken from  
170 mouse brain with  $A\beta$  accumulation. We have compared selected 401 genes  
171 with differentially expressed genes in cell lines and model animals treated with  
172 various compounds. As a result, as for three independent data sets, LINCS,  
173 DrugMatrix and GEO, top ranked compounds are reported to be tested as AD  
174 treatment. This suggests the effectiveness of our strategy and lower ranked  
175 compounds should be tested as promising drug compounds candidates. To our  
176 knowledge, this is the first successful one that can be applied to scRNA-seq in  
177 order to identify drug compounds candidate.

Table 3: Top ranked 10 compounds listed in “Drug Perturbations from GEO up” category in Enrichr. Overlap is that between selected 401 genes and genes selected in individual experiments.

Term	Overlap	P-value	Adjusted P-value
imatinib DB00619 mouse GSE51698 sample 2522	81/288	$2.27 \times 10^{-70}$	$2.05 \times 10^{-67}$
bleomycin DB00290 mouse GSE2640 sample 2851	80/329	$6.09 \times 10^{-64}$	$2.75 \times 10^{-61}$
soman 7305 rat GSE13428 sample 2640	86/532	$3.87 \times 10^{-53}$	$3.50 \times 10^{-51}$
coenzyme Q10 5281915 mouse GSE15129 sample 3464	76/302	$6.84 \times 10^{-62}$	$2.06 \times 10^{-59}$
N-METHYLFORMAMIDE 31254 rat GSE5509 sample 3570	70/283	$2.39 \times 10^{-56}$	$3.60 \times 10^{-54}$
Calcitonin 16132288 mouse GSE60761 sample 3446	65/220	$8.51 \times 10^{-58}$	$1.92 \times 10^{-55}$
cyclophosphamide 2907 mouse GSE2254 sample 3626	78/413	$2.47 \times 10^{-53}$	$2.48 \times 10^{-51}$
Calcitonin 16132288 mouse GSE60761 sample 3447	59/177	$5.88 \times 10^{-56}$	$7.59 \times 10^{-54}$
PRISTANE 15979 mouse GSE17297 sample 3229	71/291	$1.03 \times 10^{-56}$	$1.87 \times 10^{-54}$
coenzyme Q10 5281915 mouse GSE15129 sample 3456	76/396	$1.79 \times 10^{-52}$	$1.35 \times 10^{-50}$
