Abstract

Sequence functional classification has become a critical bottleneck in understanding the myriad of protein sequences that accumulate in our databases. The great diversity of homologous sequences hides, in many cases, a variety of functional activities that cannot be anticipated. Their identification appears critical for a fundamental understanding of living organisms and for biotechnological applications.

ProfileView is a sequence-based computational method, designed to functionally classify sets of homologous sequences. It relies on two main ideas: the use of multiple probabilistic models whose construction explores evolutionary information in available databases, and a new definition of a representation space where to look at sequences from the point of view of probabilistic models combined together. ProfileView classifies families of proteins for which functions should be discovered or characterised within known groups.

We validate ProfileView on seven classes of widespread proteins, involved in the interaction with nucleic acids, amino acids and small molecules, and in a large variety of functions and enzymatic reactions. ProfileView agrees with the large set of functional data collected for these proteins from the literature regarding the organisation into functional subgroups and residues that characterize the functions. Furthermore, ProfileView resolves undefined functional classifications and extracts the molecular determinants underlying protein functional diversity, showing its potential to select sequences towards accurate experimental design and discovery of new biological functions.

ProfileView proves to outperform three functional classification approaches, CUPP, PANTHER, and a recently developed neural network approach based on Restricted Boltzmann Machines. It overcomes time complexity limitations of the latter.

Key words: genome; metagenome; functional classification; protein classification; probabilistic model; profile; cryptochrome; photolyase; photoreceptor; WW domain; glycoside hydrolase; Radical SAM; Haloacid Dehalogenase; B12-binding domain containing; methylthiotransferase; SPASM/twitch domain containing.

36 1 Introduction

37 The functional classification of biological sequences has become a fundamental bottleneck to the under-
38 standing of the ever-increasing genomic and metagenomic sequence data accumulating in our databases.
39 This quest depends on the correct domain annotation of coding genes (Ponting and Dickens, 2001; Prakash
40 and Taylor, 2012; De Filippo *et al.*, 2012), which, in the past, was handled by sequence homology-, and
41 feature-based approaches.

42 The first and most intuitive approach searches for homologous sequences to already known protein or
43 domain sequences (Hawkins *et al.*, 2006; Wass and Sternberg, 2008; Loewenstein *et al.*, 2009; Clark and
44 Radivojac, 2011; Törönen *et al.*, 2018) and does it either by a direct pairwise sequence alignment or by
45 passing through protein signatures, which are descriptions of protein or domain families derived from multiple
46 sequence alignments. It is based on the “orthology-function conjecture” for which orthologues carry out
47 biologically equivalent functions in different organisms, in contrast to paralogues whose functions typically
48 diverge after duplication (Gabaldón and Koonin, 2013). Due to complex processes of evolution, many
49 homologues diversified their functions and the sequence homology approach should be applied with great
50 awareness: different similarity levels in homology should induce different levels in functional annotation
51 transfer. This represents a serious pitfall for the approach. A second pitfall, is linked to the production of
52 probabilistic models, describing conserved characteristics across sequences. Indeed, these families might be
53 made of a few members very divergent from each others (rare) or of a continuum of thousands of sequences
54 due to a lack of functional/evolutionary pressure, which challenges the family definition and produces super-
55 family/clan totally degenerated models (most frequent) of restrained use.

56 The second class of methods is based on the selection of an appropriate set of features (like short sequence
57 segments or wavelet decompositions) (Karchin *et al.*, 2005; Wen *et al.*, 2005; Wan and Jones, 2020; Bonetta
58 and Valentino, 2020). Other computational schemas use protein structure (Pazos and Sternberg, 2004; Pal
59 and Eisenberg, 2005; Lee *et al.*, 2007; Dawson *et al.*, 2017), phylogenetics and evolutionary relationships
60 (Eisen, 1998; Engelhardt *et al.*, 2005, 2011; Gaudet *et al.*, 2011; Sahraeian *et al.*, 2015; Gumerov and Zhulin,
61 2020), interaction and association data (Deng *et al.*, 2002; Vazquez *et al.*, 2003; Letovsky and Kasif, 2003;
62 Nabieva *et al.*, 2005; Sharan *et al.*, 2007; Cao *et al.*, 2014; Pham and Lichtarge, 2020) and a combination
63 of those (Shin *et al.*, 2007; Furnham *et al.*, 2012; Boari de Lima *et al.*, 2016; Cao and Cheng, 2016; Zhang
64 *et al.*, 2017; Kulmanov and Hoehndorf, 2020), with the evident dependence on the availability of different
65 data-types and a large and very diversified dataset of sequences.

66 Novel computational approaches classifying sequences by function and overcoming the limitations intrinsic
67 to existing methods would help screening sequences to design accurate experiments directed to functional
68 testing and to discover new functions. ProfileView was conceived for this purpose.

69 ProfileView is a computational method able to classify hundreds/thousands of homologous sequences into

70 functional groups. It is strongly based on the understanding of the structure of the sequence data imposed
71 by the evolutionary history of the sequences. The first main step of ProfileView is to encode functional and
72 structural information belonging to the protein family into multiple probabilistic models that capture the
73 diversity of the homologous sequences in the family. Based on the set of different models for the family,
74 the second main step of ProfileView is to define an original sequence space which organises sequences by
75 function. Biologically interpretable information and functional motifs are extracted from the classification
76 process. That is, the family members are organised in a tree structure, where subfamily delineations are
77 possible thanks to the hierarchical organisation. The presence of multiple functions in a family or subfamily
78 makes it desirable to subdivide its members into smaller groups in order to capture the differences in function-
79 related features at a level lower than the subfamily. ProfileView representative models and their specific
80 conserved motifs proved to be good indicators of this functional delineation. ProfileView can be applied on
81 a large scale on very diverse datasets.

82 In the past, the usage of multiple probabilistic models demonstrated to be powerful in the context of
83 domain annotation (Bernardes *et al.*, 2016; Ugarte *et al.*, 2018), where they showed to be highly accurate
84 on full genomes and metagenomic/metatranscriptomic datasets, allowing for the discovery of new sequences
85 enriching protein families (Fortunato *et al.*, 2016; Amato *et al.*, 2017). Here, these models are not used to
86 discover homologous sequences but to capture the variety of functional motifs characterizing a protein family.
87 Their construction demands a relatively small number of sequences (a minimum of 20), and therefore, they
88 can encode even functional motifs that are poorly represented in sequence space, generating a possibly very
89 large motifs diversification.

90 To highlight its power and generality, we applied ProfileView to seven protein families whose members are
91 characterised by a large functional diversity, multiple members are functionally well-characterised proteins
92 and subfamilies delineations have been validated experimentally together with their functional motifs: the
93 Cryptochrome/Photolyase Family (CPF), the WW domains, the glycoside hydrolase enzymes GH30 family
94 and four protein subgroups belonging to two enzyme superfamilies, the Haloacid Dehydrogenase (HAD/ β -
95 PGM/Phosphatase-like subgroup) and the Radical SAM (B12-binding domain containing, Methylthiotrans-
96 ferase and SPASM/twitch domain containing). These families and subgroups allowed us to demonstrate
97 the power in feature extraction, the simplicity in the interpretability of the results and the methodological
98 approach, and the computational efficiency of ProfileView compared to a recent artificial neural networks
99 approach to sequence classification (Tubiana *et al.*, 2019). Comparisons are also made with the PANTHER
100 classification system (Mi *et al.*, 2012, 2013) and the CUPP platform (Barrett and Lange, 2019). For each
101 protein family, ProfileView agrees with all available experimental data. Many homologous protein sequences
102 yet to be classified were classified by ProfileView in this work.

Figure 1: Schema of the ProfileView approach. **A.** Model library construction in ProfileView: all representative sequences from the Pfam domain library are selected for the domain under study. For each representative domain sequence (coloured dots), ProfileView searches for close sequences in UniProt and constructs with HH-Blits several probabilistic models making a library of models for the domain. **B.** Sequences (dots in sequence space, top center) code for proteins with different functions. ProfileView defines a probabilistic mapping from sequences onto the representation space (bottom center) which is indicative of the function of the corresponding protein sequences. The mapping is realised through the contribution of the domain probabilistic models that evaluate the probability of their match against each sequence. Each protein sequence is mapped into a vector of real numbers (coloured row in the matrix, bottom) representing the quality of the match of all models. In sequence space, sequences organise in a phylogenetic tree and, in representation space, they organise in a classification tree based on their distance. ProfileView clusters sequences in the representation space and colors them to indicate a shared function. This coloring is reported in the classification tree. **C.** Phylogenetic tree where sequences are colored as in the classification tree (B). Coloring shows a different organisation within the two trees. **D.** The classification tree allows to identify best representative models for subtrees and their characteristic functional motifs.

103 Results

104 Converting sequences in multidimensional vectors with probabilistic models

105 Our methodological approach to sequence classification, ProfileView, is outlined hereafter and illustrated
106 in **Fig. 1**. ProfileView takes as input a set of homologous sequences and a protein domain, and returns
107 a classification of the sequences in functional subgroups together with functional motifs characterising the
108 subgroups.

109 The first main idea of ProfileView is to extract conserved patterns from the space of available sequences
110 (**Fig. 1A**; see Methods) through the construction of many probabilistic models for a protein family that
111 should sample the diversity of the available homologous sequences and reflect shared structural and functional
112 characteristics. These models, called Clade-Centered Models or CCM (Bernardes *et al.*, 2016; Ugarte *et al.*,
113 2018), are built as conservation profiles. Compared to consensus models (*e.g.*, a pHMM (Eddy, 1998)), they
114 avoid the loss of functional signals when distant sequences are considered. To construct them, we consider
115 the *full* set of sequences S^i associated with a Pfam domain D^i (Finn *et al.*, 2014) and, for each sequence
116 $s_j \in S^i$, we construct a *clade-centered* profile HMM (CCM) by retrieving a set of homologous sequences
117 close to s_j from UniProt (see Methods). Such a model displays features characteristic of s_j and that
118 might differ from other domain sequences $s_k \in S^i$. The more s_j and s_k are divergent, the more CCMs are
119 expected to highlight different features. In order to capture feature characteristics of protein interaction sites
120 and/or determinants of functional specificity for protein families likely sharing the same domain architecture,
121 we built highly specific clade-centered models by considering domain sequences in UniProt that display a
122 high sequence identity to s_j . Note that in the past, we constructed CCMs to improve domain annotation
123 (Bernardes *et al.*, 2016; Ugarte *et al.*, 2018) and, for those models, we employed less restrictive conditions
124 for sequence selection in UniProt.

125 The second main idea of ProfileView is to use CCMs to embed input sequences into a multidimensional
126 representation space, where each dimension is associated with a CCM (**Fig. 1B-D**). Namely, for each input
127 sequence to be classified, each model is matched against the sequence, and the value of the match, expressing
128 how close a model is to the sequence, is recorded as a vector entry (**Fig. 1B**, left). This space is called
129 “functional space” because nearby sequences, matching similar profile motifs, are supposed to share the same
130 functional motifs. ProfileView clusters sequences (converted into vectors) within this space by hierarchical
131 clustering and provides a functional classification tree (**Fig. 1B**, bottom right). As illustrated in **Fig. 1C**,
132 the topology of the functional tree is not expected to match the one of the phylogenetic tree. Some of the
133 subtrees of the classification tree will be associated with representative probabilistic models and functional
134 motifs (**Fig. 1D**). Indeed, representative models will be used to subdivide family or subfamily members into
135 smaller groups, in order to capture differences in function-related features of the family, *i.e.* creating groups
136 that preferably include only one function. All details of the ProfileView pipeline are explained in Method.

Superfamily/ Family	Subgroup	#seqs	#filt seqs	#func seqs	Pfam domain (accession code)	Clust cond	#models
Cryptochrome/ Photolyase (CPF)	–	397	307	72	FAD (PF03441)	–	3735
WW domain	–	349	349	54	WW (PF00397)	–	3733
Glycoside hydrolase family 30 (GH30)	–	1803	1675	695	Glyco-hydro-30 (PF02055) Glyco-hydro-30-2 (PF14587)	–	1894
Haloacid Dehalogenase	HAD/ β -PGM/ Phosphatase-like	391	259	259	HAD (PF12710) HAD.2 (PF13419)	$\geq 40\%$	4075
Radical SAM	B12-binding domain containing	273	258	258	B12-binding (PF02310) B12-binding_2 (PF02607)	$\geq 60\%$	3504

	SPASM/twitch domain containing	128	29	29	SPASM (PF13186)	$\geq 60\%$	2663
		128	115	115	Radical.SAM (PF04055)	$\geq 40\%$	4501

Table I: Summary of the characteristics of the protein families used for the evaluation: number of sequences, number of sequences after filtering (steps II and III of the pipeline), number of sequences with known function, Pfam domain used for ProfileView classification, MMseq2 clustering condition to identify representative sequences in Pfam (“–” indicates no clustering), number of models constructed for ProfileView analysis. Further features are described in **Table S1** and **Table S2**.

Protein family	TP	TP+FN	Recall
Cryptochrome/Photolyase (CPF)	71	72	98.6
WW domain	54	54	100
Glycoside hydrolase family 30 on EC numbers	34	34	100
Glycoside hydrolase family 30 on CAZy families	694	695	99.8
HAD/ β -PGM/Phosphatase-like	259	259	100
B12-binding domain containing	253	258	98.1
Methylthiotransferase	380	393	96.7
SPASM/twitch domain containing with SPASM domain	29	29	100
SPASM/twitch domain containing with Radical SAM	114	115	99.1

Table II: **Summary of ProfileView performance in classifying functionally characterised sequences.** To evaluate what proportion of sequences with a characterised function (TP+FN; see column “# func seqs” in **Table I**) is correctly classified (TP) by ProfileView, we use the Recall measure (TP/TP+FN; see Methods).

137 Seven protein families analysed with ProfileView

138 ProfileView was ran on seven different protein families listed in **Table I** (see **Table S1** and **Table S2** for
139 further characteristics) and was validated on their known functionally characterised sequences. In **Table II**,
140 we provide a quick summary of ProfileView performance by reporting what proportion of sequences is
141 correctly classified by ProfileView for each protein family (see Methods). ProfileView identified a large
142 number of functionally known positions and specific protein residues in interaction with either nucleic acids,
143 amino acids or small molecules. For two families, the Cryptochrome/Photolyase Family (CPF) and the
144 WW domain family, we shall show in detail how ProfileView can provide a functional classification for a
145 large number of functionally uncharacterised sequences, and novel information on conserved amino acids
146 that could be useful to design testing experiments.

147 ProfileView on the CPF family

148 The Cryptochrome/Photolyase Family (CPF), involved in the interaction with nucleic acids, amino acids and
149 small molecules, is widely distributed in all kingdoms of life (Jaubert *et al.*, 2017; Sancar, 2003; Brettel and
150 Byrdin, 2010; Chaves *et al.*, 2011). CPF members share the same fold, yet can perform very different func-
151 tions and have completely different partners: cryptochromes (CRY) are mainly photoreceptors using light
152 to activate specific signalling pathways; some CRY also acts as light-independent transcriptional regulators
153 of the circadian clock; photolyases (PL) are light-activated enzymes repairing UV-damaged DNA (CPD or
154 (6-4) lesions). All CPFs non-covalently bind FAD (Flavin Adenine Dinucleotide) and share a mechanism of
155 FAD photoreduction by intra-protein electron transfer (Björn, 2015). The different CPF functional classes
156 are described in **Supplemental File** (section 1) and listed in the inset legend of **Fig. 2** (bottom right).

157 In our analysis, we make the hypothesis that the FAD (flavin adenine dinucleotide) binding domain,
158 occurring in all CPF sequences, contains all functional information leading to a functional diversification of
159 the family. Indeed, the FAD binding domain is known to non-covalently bind the FAD chromophore which
160 can be in different oxidation and protonation states (Sancar, 2003) specifically associated with different
161 functions. It is also known to interact specifically either with the damaged DNA, with other domains
162 present in CPF proteins (*e.g.*, C-ter extensions in some photoreceptor cryptochromes) or with other protein
163 partners (Czarna *et al.*, 2013).

164 ProfileView is validated on two different types of data: functionally characterised CPF sequences and
165 functionally characterised positions within CPF sequences. These latter are compiled in a manually cu-
166 rated list of positions (**Supplemental File** “CPF_mutants_used_for_validation.xlsx”) from the literature.
167 Furthermore, we combined them with structural modelling to analyse CPF subgroups in detail.

168 **Validation of ProfileView on the functional diversity of CPF members.** The ProfileView repre-
169 sentation space shows a consistent functional organisation of CPF sequences (**Fig. 2C** and **Fig. S1**) since
170 sequences known for having the same functional characterisation occur together in large subtrees of the Pro-
171 fileView classification tree. The perfect split of 71 out of 72 functionally characterised CPF sequences within
172 the 11 subtrees allows us to uniquely associate each subtree with a known functional class (see **Table S3**).
173 This provides the first proof of the method’s classification power.

174 Most importantly, at the root, the ProfileView tree topology organises large subtrees consistently with
175 known functional classes (**Fig. 3A**). Namely, the ProfileView tree separates light-independent circadian
176 transcriptional regulator CRYs from the light-dependent (6-4) photolyases (PLs) and animal photoreceptor
177 cryptochromes (PR CRY; (**Fig. 3E**, top)). It also clearly separate the DNA repair (6-4) PL from the
178 PR CRY. It reconciles classes I and III cyclobutane pyrimidine dimer (CPD) PLs into a single subtree,
179 while keeping them distinct, and it clearly separates them from plant and plant-like PR CRYs (**Fig. 3F**,
180 top). For the characterised sequences displaying double function (**Fig. S1**), their DNA repair/photolyase

Figure 2: ProfileView representation space and classification tree for the CPF family, and compatibility with experimental work. **A.** 2-dimensional projection of the ProfileView representation space for 307 FAD-binding domain CPF sequences obtained by Principle Component Analysis (PCA). The axes correspond to the first and second PCA components explaining the 63.8% and 17.6% of the dispersion, respectively. Colors correspond to sequences that are either experimentally functionally classified (see the colour legend “Function”) or unclassified (light grey). When a sequence is known to have a double function, it is reported with two colours (the inside colour refers to the known primary function). **B.** As in A, where unclassified points in A are classified by using hierarchical clustering (see the colour legend “Cryptochrome/Photolyase Family”). **C.** The ProfileView classification tree is a finer representation of the hierarchical clustering realised on the high dimensional representation space and illustrated in B. Colors of subtrees are identified by representative models and correspond to known CPF classes (inset legend, right), with the exception of the NCRY subtree. External coloured labels define known functions for the sequences (inset legend, left). Some of the 307 sequences are known to hold multiple functions and are labelled by two colors. The function “signalling” (dark grey) refers to signalling processes of different nature (photoreceptor, transcription, unknown). Numbers on the internal nodes correspond to the percentage of sequences in the corresponding subtree that are separated from the remaining sequences in the tree by the best representative model occurring in the model library (see **Fig. S1** for details).

Figure 3: Topological comparison between the ProfileView classification tree and the phylogenetic trees for the CPF family and the FAD binding domain. **A.** Schema illustrating the topological structure of the ProfileView tree in **Fig. 2C** and **Fig. S1**. Colors correspond to groups of sequences clustering together and comprising sequences with known function (bottom). The domain architectures known to be characteristic of each subtree is reported (see **B** for more details). **B.** Domain architectures for proteins belonging to different subtrees of **A** are reported (colours as in **A**). **C.** and **N.**-terminal regions are indicated with grey boxes. Dotted border lines indicate terminal regions only present occasionally in an architecture. **C.** Scheme of the main topological structure of the CPF phylogenetic tree constructed from the 307 CPF sequences containing the FAD binding domain. Colors as in **A**. See the CPF phylogenetic tree in **Fig. S3**. **D.** Scheme of the main topological structure of the FAD phylogenetic tree constructed from the 307 FAD-binding domain sequences. Colors as in **A**. See the FAD phylogenetic tree in **Fig. S4**. **E., F.** Two zooms on subtrees of the ProfileView classification tree involving classes of CPF sequences described in **A**. Colors as in **A**.

181 activity (either CPD or (6-4)) is consistently determined by ProfileView that groups these sequences in
182 the photolyase subtrees. At the best of our knowledge, these sharp separations, in agreement with known
183 functional characterisations, have never been obtained by sequence analysis before.

184 Interestingly, the ProfileView tree allowed for the identification of a yet functionally uncharacterized
185 subtree (named NCRY; see **Fig. 2C** and **Fig. 3A**) of proteins showing strong sequence divergence. The
186 same subtree was also identified by sequence similarity network analysis in (Emmerich *et al.*, 2020) without
187 inferring any functional classification for it, and by the phylogenetic tree based on the FAD binding domain
188 in CPF sequences (FAD tree, for short; **Fig. 3D**). ProfileView positions NCRY close to the Plant PR CRY
189 and plant-like PR CRY. In contrast, the phylogenetic tree of CPF sequences (CPF tree, for short) includes
190 NCRY within class I CPD PL and the FAD tree places it close to the animal PR CRY and CRY DASH. To
191 our knowledge only one protein from this family has been characterised and it was shown to bind FAD but
192 to lack DNA repair/photolyase activity (Worthington *et al.*, 2003) which is in accordance with the position
193 of this family in our functional tree. This finding highlights the potential of ProfileView to reveal novel
194 functional classes within a protein family. (See also **Fig. S2**.)

195 **Comparison of the ProfileView tree with the FAD and CPF phylogenetic trees.** The comparison
196 of ProfileView classification tree (**Fig. 2C**) with the CPF tree (**Fig. S3**) and the FAD tree (**Fig. S4**)
197 highlights important differences in the topological organisation of major functional classes. A cartoon in
198 **Figs 3ACD** compares the three trees for easy visualization. We notice that the CPF phylogenetic tree
199 (**Fig. 3C**): 1. incorrectly groups sequences exhibiting disparate functions, for instance plant PR CRY and
200 plant-like PR CRY are clustered within class III CPD PL; 2. hides the NCRY subtree within class I CPD
201 PLs; 3. mixes light-dependent and light-independent proteins in a subtree where animal PR CRY and
202 circadian transcriptional regulators are clustered within (6-4) PL sequences. Furthermore, the compatibility
203 of domain architectures associated with different functional classes of CPF sequences (**Fig. 3B**) is coherent
204 with the ProfileView tree topology (**Fig. 3A** bottom) and much less so with the CPF phylogenetic tree.
205 Compare, for instance, the architectures for the classes plant-like PR CRY, plant PR CRY and NCRY, or
206 those for classes I and III CPD PLs. All members of these classes have a PHR domain in which a specific CPF
207 FAD binding domain is found, but C- and N-ter extensions of variable sequence or length. The architectures
208 for plant-like PR CRY, plant PR CRY and NCRY possess N- or C-ter extensions whereas classes I and
209 III CPD PLs only possess the PHR domain. Classes which are topologically close in the ProfileView tree
210 preserve sequence/length characteristics of C- and N-ter regions and agree with what is expected in contrast
211 to the subtrees of the CPF phylogenetic tree.

212 Similar observations can be highlighted by comparing the ProfileView tree with the FAD phylogenetic
213 tree (**Fig. 3D**).

214 Summarizing, the reconstruction of ProfileView tree topology highlights three important results: 1. the

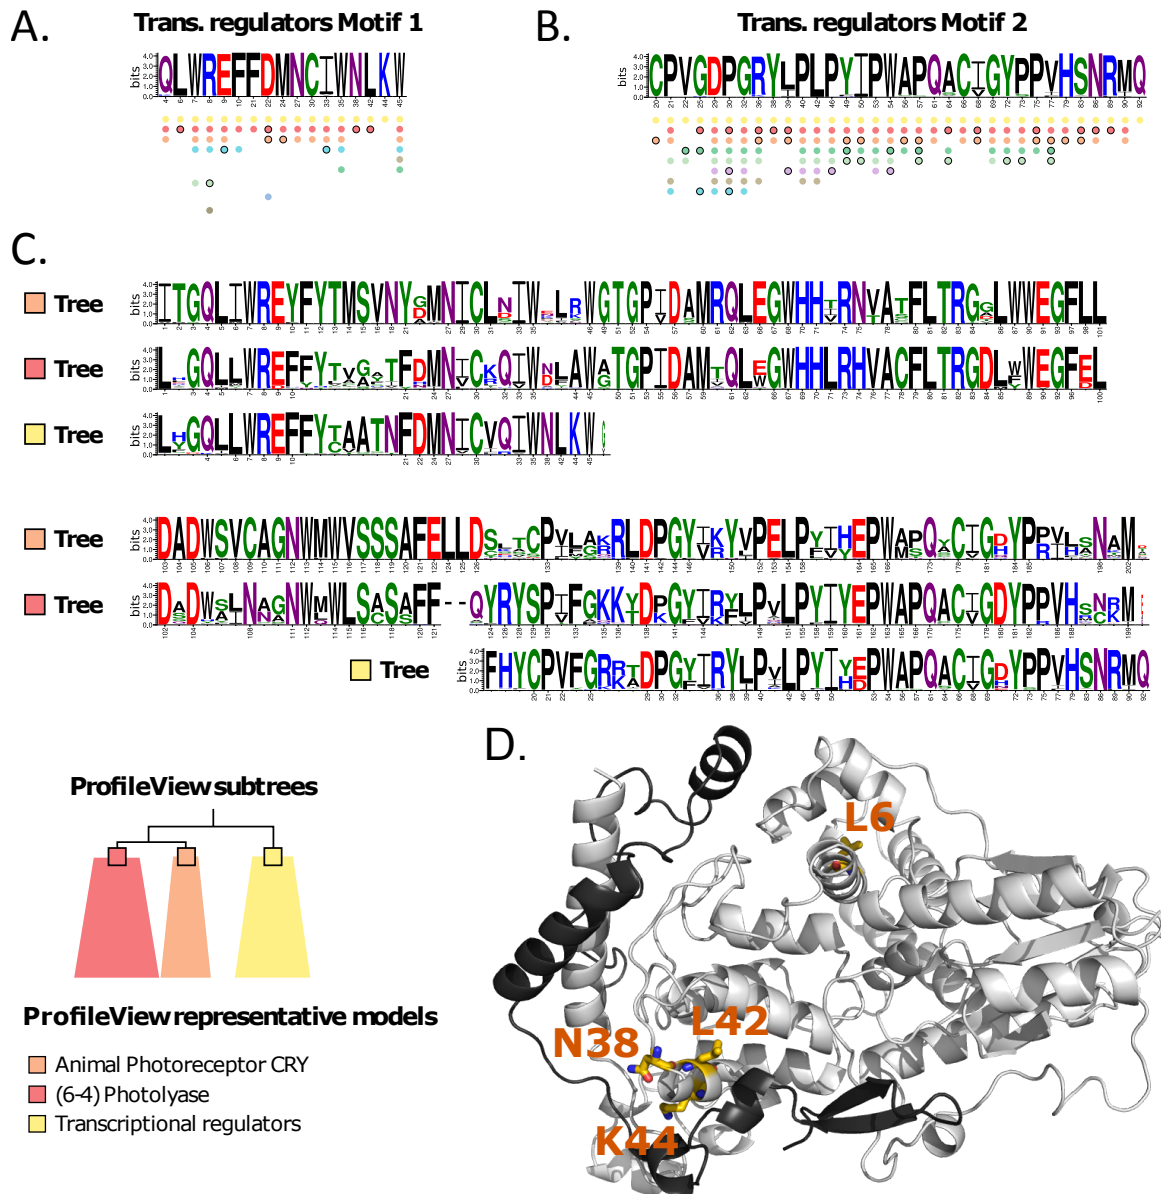

Figure 4: Trans. regulators motifs and their comparison with (6-4) PL and animal PR CRY motifs. **A, B:** two motifs of conserved residues present in light-independent transcriptional regulator sequences. They are extracted from two representative models of the sequences (described in **Fig. S7**) comprising the “yellow” subtree of **Fig. 3AE** (see also bottom). Numbers (under the letters) correspond to positions in a model, and they are not comparable between motifs. Coloured dots, piled below the motifs, indicate that the corresponding position is well-conserved (see Methods) for the subtrees with the same colour in **Fig. 3A**. Circled dots indicate positions that are less conserved (see Methods). For each motif, coloured dots are ordered, from top to bottom, depending on the best E-values given by **hhblits** to the pairwise alignments. **C.** Three representative motifs associated with the trans. regulators (yellow), (6-4) PL (red) and animal PR CRY (orange) subtrees of the ProfileView tree are aligned. Numbered positions correspond to conserved positions belonging to the associated representative motif. The absence of the number indicates less conserved positions. The alignment has been constructed using trans. regulators motifs as template models and all others as query models. The length of a motif depends on the length of the associated model, selected as best representing the sequences in a subtree. **D.** PDB structure (4CT0) of the interacting mouse cryptochrome mCRY1 (grey) and Period2 mPER2 (black) involved in the circadian clock. The four residues highlighted in the structure, N38, L42, K44 and L6, have been explained in the text.

215 resolution in two functional groups of light-independent proteins (transcriptional repressor CRY) and pro-
216 teins which bind the FAD chromophore and need light for their function (PL and PR CRY; **Fig. 3E**); 2.
217 the resolution of classes I and III CPD PL into two distinct sibling subtrees (**Fig. 3F**); 3. the prediction of
218 possible novel functions, by the identification of novel groups as NCRY (**Fig. 3F**).

219 **Representative models, motifs and the validation of ProfileView on functionally characterized**
220 **positions.** ProfileView associates representative models and functional motifs to the subtrees of its clas-
221 sification tree. They are used to highlight subfamily delineations and molecular determinants underlying
222 functions and interactions, respectively.

223 A representative model for a subtree of the ProfileView tree is a probabilistic model that, ideally, “sep-
224 arates” the sequences in a subtree from all other sequences in the ProfileView tree (see step IX of the
225 ProfileView pipeline in Methods). Representative models can be used to subdivide family or subfamily
226 members into smaller groups, in order to capture differences in function-related features at a lower level, i.e.
227 creating groups that preferably include only one function. We remark that all “functional” CPF subtrees
228 corresponding to known subfamilies, highlighted by distinguished colors in **Fig.2C** and **Fig. S1**, are char-
229 acterised by a representative model which separates at least 50% of the subtree sequences from all other
230 sequences in the ProfileView tree. Moreover, we found representative models associated with several of the
231 internal nodes of the ProfileView tree (**Fig. S1**, where the proportion of sequences supported by a model is
232 indicated on the nodes), and many models separate subtree sequences sharply (100%) indicating functional
233 diversity. An automatic procedure in ProfileView identifies representative models.

234 Given a representative model for a subtree, the set of conserved positions in the model univocally defines
235 a motif for the corresponding subtree. Motifs associated with the 11 functional subtrees are reported in
236 **Figs. S5, S6** with the exception of classes I and III CPD PL, known to share the same function, that we
237 grouped together by considering the representative model of the minimal subtree including both classes.
238 The only subtree where we found two distinct representative motifs, covering two different regions of the
239 FAD binding domain sequence, is the light-independent transcriptional regulator tree (**Fig. 4AB**). When
240 comparing with the other models, these two models are the only ones which do not cover the FAD binding
241 domain region directly involved in proton or electron transfer to the FAD chromophore, as illustrated in
242 **Fig. 4C** with the alignment of the two transcriptional regulator motifs, the (6-4) PL motif and the animal
243 PR CRY motif. This alignment indirectly shows that proton/electron transfer is not involved in the function
244 of light-independent transcriptional repressors (**Fig. 4C**) despite the importance of the FAD chromophore
245 in their regulation (Hirano *et al.*, 2017).

246 To validate ProfileView motifs, we exploited the functional information derived by characterized mutations
247 and looked whether their conserved amino acid positions would identify known functional natural variations,
248 single amino acid residue replacements by site-directed mutagenesis or random mutagenesis, and structural

249 specificity when structures were available. For this, we manually curated a list of experimentally character-
250 ized positions in CPF sequences (see **Supplemental File** “CPF_mutants_used_for_validation.xlsx”). Most
251 of these positions display mutations causing loss of function or phenotypic changes. They are often involved
252 in binding with other proteins, DNA substrates or with the cofactor FAD; active amino acids involved in
253 catalytic or allosteric sites, such as DNA repair for PLs or post-translational modifications in CRY, are also
254 identified. **Table S3** summarizes how many ProfileView positions are validated by current experimental
255 evidence. Interestingly, it finds a number of highly specific positions for CPF functional classes that have
256 not been reported in the literature before. We discussed these positions together with other observations in
257 **Supplementary File**. They illustrate the great deal of functional information that can be extracted from
258 representative motifs and be used to design tailored experiments for discovering new functional activities or
259 novel biological mechanisms involving the FAD binding domain.

260 **How evolutionary close sequences are distinguished by motifs in ProfileView classification**
261 **space?** ProfileView can distinguish very similar sequences associated to different functions. We illustrate
262 this crucial feature with a concrete example, based on representation models and motifs. We consider the pair
263 of sequences U5NDX3 and R7UL99, belonging to the CPF family. They are grouped together by phylogenetic
264 analysis because very similar (sequence identity is 61.8% and sequence similarity is 74.7%) and are classified
265 in different functional groups by ProfileView, as a photolyase and a transcriptional regulator respectively.
266 The conserved positions belonging to the photolyase functional motif (motif called “(6-4) photolyase” in
267 **Fig S5**) constructed from ProfileView analysis are shown in the alignment reported in **Fig. S8**. For almost
268 all positions in the motif, the corresponding amino acid is conserved in both sequences (in green) as expected
269 by the high sequence identity of the alignment. For positions 1, 33 and 135 in the motif, the amino acid is
270 conserved only in the U5NDX3 sequence. This means that the photolyase representative model will provide
271 higher matching values for U5NDX3 than for R7UL99. Moreover, two of these positions, 1 and 135, are
272 highly conserved in the photolyase family and variable in the transcriptional regulator family (see dots below
273 the motif in **Fig S5**) making the U5NDX3 sequence closer in classification space to the photolyase subgroup
274 than R7UL99. Note that these observations concern the dimension of ProfileView classification space which
275 is associated with the “(6-4) photolyase” model, but that is the contribution of all probabilistic models, one
276 for each dimension of the classification space, that will define the position of the sequences bringing them
277 closer either to the photolyase subgroup or the transcriptional regulator subgroup, in this specific example.

278 A second example is reported in **Fig. S9** for sequences Q6MDF3, D8UF46 and Q485Z2, where the
279 phylogenetic tree could wrongly suggest an ancestral function, conserved in paraphyletic groups separated
280 by clades where neofunctionalization would occur. The analysis of the sequence alignment (see legend in
281 **Fig. S9**) highlights those positions explaining functional classification.

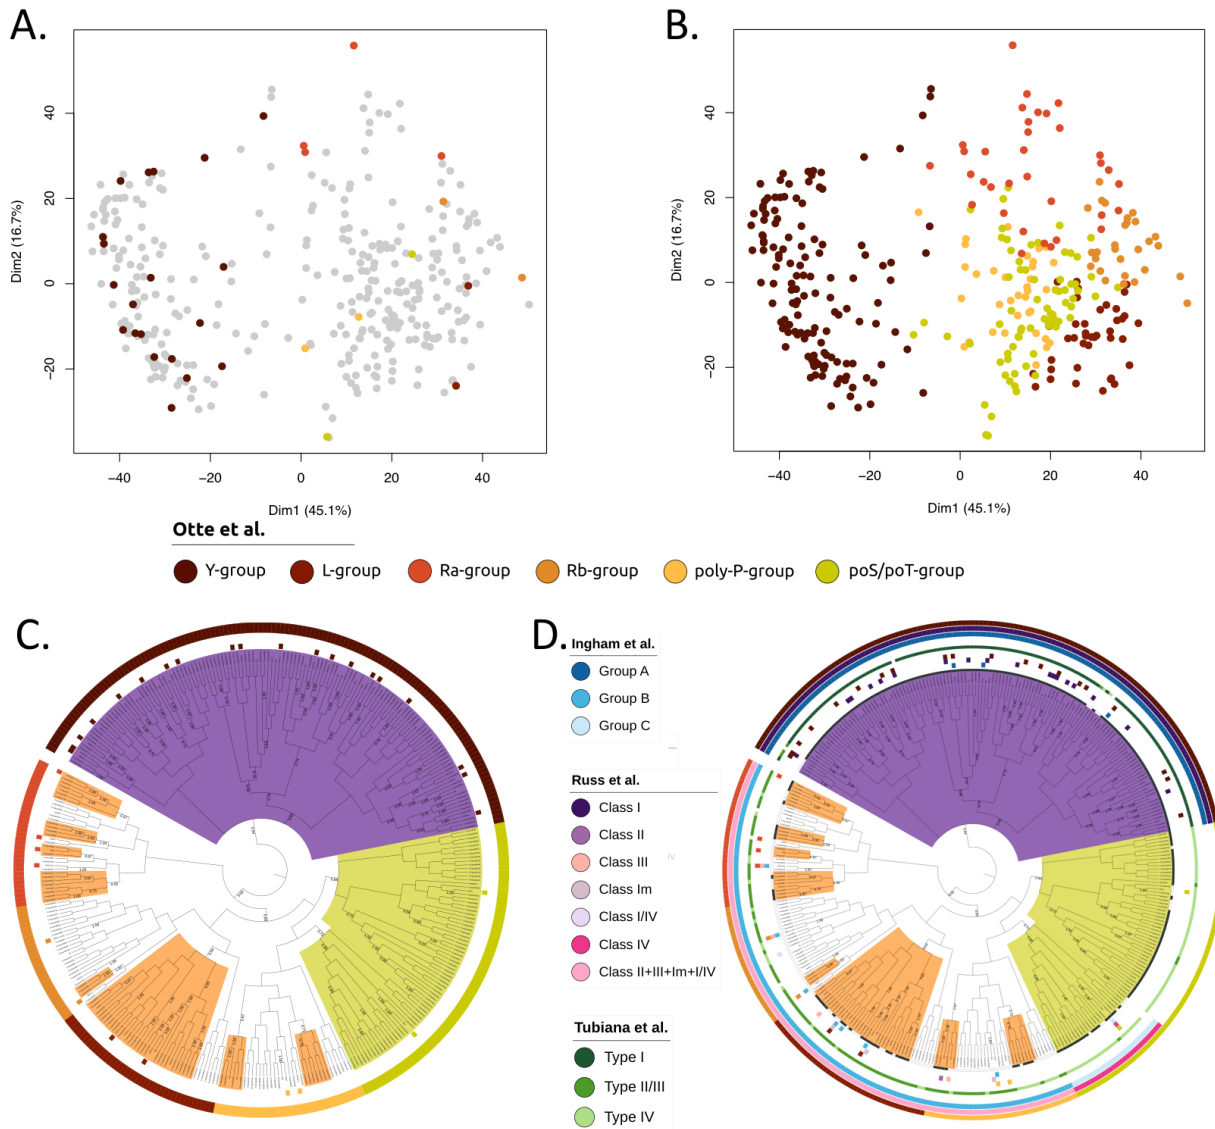

Figure 5: ProfileView representation space and ProfileView tree for WW domains; compatibility with experimental and computational classification. **A.** 2-dimensional projection of the ProfileView representation space for the WW domain natural sequences studied in (Otte *et al.*, 2003; Ingham *et al.*, 2005; Russ *et al.*, 2005; Tubiana *et al.*, 2019) obtained by PCA. The first and second PCA components explain 45.1% and 16.7% of the dispersion, respectively. Colors follow Otte’s functional classification of 32 WW sequences (Otte *et al.*, 2003); sequences not classified in (Otte *et al.*, 2003) are in light grey. **B.** As in A, where light grey sequences are classified by ProfileView in subsets associated with Otte’s functional classes (Otte *et al.*, 2003) by hierarchical clustering (see main text). **C.** The ProfileView tree represents the hierarchical clustering, realised on the high dimensional ProfileView space; see B. All subtrees with a representative model are indicated by a root labeled by the percentage of sequences in the subtree best matching the model (see Methods). Among these subtrees, those containing at least 3 sequences are coloured. 54 coloured squares are reported as functionally characterised, and 6 more were left unclassified in (Otte *et al.*, 2003; Ingham *et al.*, 2005; Russ *et al.*, 2005) (KIAA1052, PRP40-1, CA150-1, CA150-3, HYP109-2, IQGAP1). The 6 WW unclassified sequences are classified by us in different subtrees corresponding to different Otte’s groups: PRP40-1, CA150-1 in L-group; HYP109-2, IQGAP1 in Ra-group; CA150-3 in Rb-group; KIAA1052 in poS/poT-group. **D.** Same tree as in C, where sequences in a coloured subtree that are best matched by the representative model are highlighted in black in the first circular stripe surrounding the tree. As in C, the three experimental characterisations of natural sequences are reported in three layers made of small squares around the tree: “Otte” (Otte *et al.*, 2003) (brown scale; as in C), “Ingham” (Ingham *et al.*, 2005) (blue scale) and “Russ” (Russ *et al.*, 2005) (purple scale). “Tubiana” computational classification (Tubiana *et al.*, 2019) is reported in green scale; WW sequences not considered in Tubiana are left white. The three most external circular stripes show the compatibility between the grouping suggested by Otte, Russ and Ingham with ProfileView subtrees as described in **Table I**. The larger subtree comprising a given function, in the sense of either Otte, Russ and Ingham, gives the colour of the function to the corresponding portion of the stripe. Note that one of our trees is not functionally annotated by experimental data coming from Ingham nor Russ. (See **Fig. S11** and **Table I**.)

282 ProfileView on the WW domains

283 The WW domain family is found in many eukaryotes. WW domains are protein modules mediating protein-
284 protein interactions through recognition of proline-rich peptide motifs and phosphorylated serine/threonine-
285 proline sites. They are involved in a number of different cellular functions (Ingham *et al.*, 2005) such as
286 transcription, RNA processing, receptor signalling and protein trafficking, and in several human diseases
287 such as muscular dystrophy, cancer, hypertension, Alzheimer's, and Huntington's diseases. Their functional
288 classification is far from being straightforward because based on the sequence motif and the binding affinity
289 of the peptides targeted by WW domains. In particular, the same WW domain can bind with variable
290 affinity to multiple peptides (Sudol and Hunter, 2000; Otte *et al.*, 2003; Russ *et al.*, 2005), and it is the
291 modulation of binding properties that make hundreds of WW domains to interact specifically with hundreds
292 of putative ligands in mammalian proteomes (Sudol and Hunter, 2000). WW domains have been experimen-
293 tally classified in six interaction groups by Otte *et al* (Otte *et al.*, 2003) (Y, R_a, R_b, L, poly-P, poS/poT),
294 in 3 groups by Ingham *et al* (Ingham *et al.*, 2005) (A, B and C) and in 6 groups by Russ *et al* (Russ *et al.*,
295 2005) (I, Im, I/IV, II, III, IV). These three functional classifications were based on target peptide sequence
296 motifs and their binding affinity. (**Fig. S10** shows the localisation of known classified sequences on the
297 phylogenetic tree for WW domains.)

298 **Validation of ProfileView on the functional diversity of WW domains.** All natural sequences (60)
299 analysed in (Otte *et al.*, 2003; Ingham *et al.*, 2005; Russ *et al.*, 2005) and upgraded with a set of 289 natural
300 sequences randomly selected from (Tubiana *et al.*, 2019) and not yet experimentally characterized, have
301 been considered for classification by ProfileView. Of the 60 experimentally tested natural sequences, 54 of
302 them have been experimentally functionally characterized (**Table I**).

303 ProfileView tree is organised in seven subtrees as illustrated in **Fig. 5** and **Fig. S11**. The three indepen-
304 dent experimental characterisations classify the 54 sequences in groups/classes that turn out to belong to
305 specific ProfileView subtrees as shown in **Table S4**, and in **Fig. 5** and **Fig. S11** by the three first internal
306 layers of colored squares (corresponding to the 54 characterised sequences). In other words, ProfileView
307 perfectly classifies the 54 known functionally characterised sequences: the 35 sequences in Ingham's group
308 A, Russ's class I and Otte's Y-group are grouped together in one large ProfileView subtree (T_1 in **Table S4**
309 and **Fig. S11**); the 2 sequences in Ingham's group C, Russ's class IV and Otte's posS/posT-group are
310 grouped in two main ProfileView subtrees (T_6 & T_7 in **Table S4** and **Fig. S11**); the remaining 17 sequences
311 are organised in 4 other ProfileView subtrees corresponding to 4 different Otte's groups (T_2 to the L-group,
312 T_3 to the Ra-group, T_4 to the Rb-group and T_5 to the posS/posT-group; see **Table S4** and **Fig. S11**).

313 When comparing ProfileView classification to Russ' study, it is interesting to consider the nature of this
314 latter. Indeed, Russ *et al* look at combinations of binding specificities of WW domain sequences to different
315 peptides and classifies them in 6 classes accordingly. Sequences in classes Im, I/IV, II and III display

316 complex binding patterns involving different proline-rich peptide motifs whose differentiation is not obvious.
317 Accordingly, these sequences belong to various ProfileView subtrees (*e.g.* class III sequences are spread on
318 subtrees T_2 - T_5), different from those involving class I and class IV. Therefore, in **Fig. 5** and **Fig. S11** (see
319 pink color in the outer circle) and in **Table S4**, we grouped classes Im, I/IV, II and III together.

320 As shown in **Fig. 5**, not all the seven ProfileView subtrees are associated with a unique representative
321 model (see legend). Multiple models might be associated to subtrees and describe different groups of
322 sequences within the class, suggesting a finer functional organisation for this subfamily of WW domains. All
323 identified representative models are reported in **Fig. S12** and their associated motifs in **Figs. S13, S14**.

324 ProfileView on the GH30 family of the CAZy database

325 The glycoside hydrosylases (EC 3.2.1.-), in short GH, are a widespread group of enzymes which hydrolyse
326 the glycosidic bond between two or more carbohydrates or between a carbohydrate and a non-carbohydrate
327 moiety. Their classification, based on substrate specificity and occasionally on molecular mechanisms, turned
328 out to be particularly difficult. For this, a vast knowledge about these enzymes has been meticulously curated
329 in the CAZy database (Lombard *et al.*, 2014). The GH30 is one of the GH families that has been organised
330 in subfamilies in CAZy (<http://www.cazy.org/GH30.html>). It counts nine different subfamilies (GH30-1,...,
331 GH30-9) corresponding to eleven different enzymatic chemical reactions. Some of these subfamilies are
332 functionally classified by CAZy and some others are left unclassified.

333 **Validation of ProfileView on the functional diversity of GH30 sequences.** We considered the set
334 of GH30 sequences and their classification in CAZy. ProfileView representation space and ProfileView tree
335 for these sequences have been constructed using models coming from two similar PFAM domains, PF02055
336 (Glyco_hydro_30) and PF14587 (Glyco_hydr_30_2). The topology of the ProfileView tree (**Fig. S15** and
337 **Fig. S23B**) perfectly separates sequences in the nine CAZy subfamilies GH30-1,..., GH30-9 into subtrees
338 (only one GH30-3 sequence is placed within GH30-2 sequences). Furthermore, the subtrees well separate
339 the EC numbers in CAZy functional annotation (see **Fig. S15**, **Table S5** and **Table S6**).

340 Four subfamilies (GH30-1, GH30-2, GH30-7 and GH30-9) are characterised by representative models
341 directly explaining the separation of their sequences from all other GH30 sequences in the tree (**Fig. S23B**).
342 In **Fig. S15**, the grey dots indicate the existence of representative models for many ProfileView subtrees,
343 highlighting a possible functional sub-characterization for several CAZy subfamilies. For instance, note that
344 the two CAZy reactions 3.2.1.45 and 3.2.1.21+3.2.1.37 for GH30-1 are identified in distinguished subtrees
345 (green and violet labels are associated to reactions 3.2.1.45 and 3.2.1.21+3.2.1.37 in **Fig. S15**) separated
346 by a representative model. Furthermore, for the GH30-3 subfamily, several sequences labelled by CAZy
347 reaction 3.2.1.75 occur in different GH30-3 subtrees characterized by representative models, highlighting
348 potential functional differences within this subfamily.

349 **ProfileView on the enzyme superfamilies of the Structure-Function Linkage Database**

350 The Structure-Function Linkage Database (SFLD) is a manually curated classification resource describing
351 structure-function relationships for functionally diverse enzyme superfamilies (Schnoes *et al.*, 2009; Akiva
352 *et al.*, 2014). Despite their different functions, members of these superfamilies “look alike” making them easy
353 to misannotate. We challenge ProfileView against these sets of sequences and show that its classification
354 meets the functional information in SFLD.

355 SFLD is organised in superfamilies whose members are subdivided into subgroups using sequence in-
356 formation, and lastly into families, that is sets of enzymes known to catalyze the same reaction using the
357 same mechanistic strategy. Subgroups are not organised by function, and the functional specificity of the
358 sequences is detailed at the family level. We consider two different superfamilies, Haloacid Dehydrogenase
359 and Radical SAM, because of their large variety of functions. Indeed, the Haloacid Dehydrogenase family is
360 characterized by 25 subgroups organized in 22 families and 20 different reactions, and the Radical SAM fam-
361 ily by 58 subgroups organised in 98 families and 85 reactions (see [sfld.rbvi.ucsf.edu/archive/django/
362 superfamily/index.html](http://sfld.rbvi.ucsf.edu/archive/django/superfamily/index.html) for a detailed description). We analysed the HAD/ β -PGM/Phosphatase-like sub-
363 group of Haloacid Dehydrogenase and three subgroups of Radical SAM: B12-binding domain containing,
364 Methylthiotransferase and SPASM/twitch domain containing. ProfileView functional classification has been
365 validated on the SFLD families associated with the four subgroups.

366 **ProfileView on the HAD/ β -PGM/Phosphatase-like subgroup.** Characterized functions included
367 in this subgroup include 2-haloacid dehalogenase, beta-phosphoglucomutase, phosphonoacetaldehyde hy-
368 drolase, and phosphatases of various specificities (see [sfld.rbvi.ucsf.edu/archive/django/subgroup/
369 1129/index.html](http://sfld.rbvi.ucsf.edu/archive/django/subgroup/1129/index.html)). We run ProfileView on a model library constructed from the two similar Pfam domains
370 HAD and HAD_2 (see Table I). ProfileView groups all known sequences belonging to known characterized
371 functions correctly, in separated subtrees, as illustrated in **Fig. S16** and **Table S7**. Moreover, for each sub-
372 tree, it provides a model separating the set of sequences in the subtree from the rest of the set. The exception
373 relies on one family, the 2-deoxyglucose-6-phosphatase which is grouped with the glycerol-3-phosphate phos-
374 phatase, represented by only two sequences correctly grouped together, and for which a model separates
375 both functions from the rest of the tree.

376 **ProfileView on the B12-binding domain containing subgroup.** All the enzymes in this subgroup
377 appear to have a Vitamin B12 Binding domain and are involved in many different reactions (see [sfld.
378 rbvi.ucsf.edu/archive/django/subgroup/1082/index.html](http://sfld.rbvi.ucsf.edu/archive/django/subgroup/1082/index.html)). We run ProfileView on a model library
379 constructed from the two similar Pfam domains B12-binding and B12-binding_2 (see **Table I**). **Fig. S17**
380 and **Table S8** describe ProfileView classification in three large subtrees associated with three families, which
381 are represented by tens of sequences. The remaining five families are underrepresented, four comprise exactly

382 one sequence and the fifth one only three sequences (grouped together by ProfileView, see “paromamine de-
383 oxygenase” in **Fig. S17**). Underrepresented families are localised within two large subtrees of the ProfileView
384 classification tree, the bacteriocin maturation and the hopanetetrol cyclitol ether synthase (see **Fig. S17**).
385 Consistently, note that ProfileView does not propose a model separating these two large subtrees but it
386 proposes one separating the anaerobic magnesium-ptotoporphyrin-IX monomethyl ester cyclase family from
387 the rest.

388 **ProfileView on the Methylthiotransferase subgroup (MTTase).** All enzymes of this subgroup are
389 organised around 4 families (see sfld.rbvi.ucsf.edu/archive/django/subgroup/1061/index.html) that
390 have been defined in SFLD by considering the domain architecture of MTTase sequences comprising an N-
391 terminal MTTase domain, a central radical generating fold domain and the C-terminal TRAM domain, not
392 shared by other Radical SAM outside the MMTase. In contrast, to classify MTTase sequences, we used the
393 Radical SAM domain only, shared by all subgroups of the superfamily. This domain allowed ProfileView to
394 split the sequences in 4 main subtrees corresponding to the four known families as reported in **Fig. S18**
395 and **Table S9**. A few sequences are misplaced compared to SFLD classification. ProfileView proposes
396 many models splitting the four families. In particular, it proposes two representative models splitting the
397 MiaB-like and CDK5RAP1 families from the rest and viceversa (**Fig. S18**).

398 **ProfileView on the SPASM/twitch domain containing subgroup.** We used ProfileView to study
399 this subgroup (see sfld.rbvi.ucsf.edu/archive/django/subgroup/1067/index.html) through two in-
400 dependent analysis, one based on the Radical SAM domain and other on the SPASM domain. This is
401 an intrinsically difficult set, not only for functional annotation but also for domain annotation. Indeed,
402 we identified the SPASM domain in 29 sequences based on the ProfileView model library of 4501 SPASM
403 models, while only 6 of these sequences have been annotated by Pfam with a SPASM domain. ProfileView
404 classification of the SPASM/twitch domain containing sequences based on SPASM domain organises the
405 seven known SFLD functional families in distinct subtrees (see **Fig. S19** and **Table S10**). **Fig. S20** and
406 **Table S11** describe ProfileView classification based on Radical SAM domain. Families are well organised
407 in distinguished subtrees supported by representative models.

408 **Comparison of ProfileView with other computational approaches**

409 ProfileView is compared with the PANTHER classification system (Mi *et al.*, 2012, 2013), the state-of-the-
410 art neural network approach based on Restricted Boltzman Machines (RBM) in (Tubiana *et al.*, 2019), and
411 the CUPP platform (Barrett and Lange, 2019). In all comparisons it proves to overcome or be on par with
412 the functional classification considered.

413 **ProfileView and PANTHER.** PANTHER (Mi *et al.*, 2012, 2013) is a large curated biological database

414 of gene/protein families and their functionally related subfamilies which has been designed to classify and
415 identify the function of gene products. PANTHER provides data and tools to group sequences in functional
416 clusters. Contrary to ProfileView, it does not organise them in a distance tree, missing the possibility to
417 identify large-scale functional properties for groups of sequences clustering together, like the light depen-
418 dent/independent CPF sequences. Comparison was realised on the full CPF family. For easier visualization,
419 we reported PANTHER classification on both the ProfileView classification tree and the CPF distance tree in
420 **Figs S21** and **S22**. ProfileView and PANTHER agree on several functional classes: “SLR1343 PROTEIN”
421 for PANTHER and CRY Pro for ProfileView; “ZGC:66475” PANTHER and Class II CPD PL for ProfileView.
422 Other PANTHER groups are function specific but they do not recognise the full functional subgroup, such as
423 “CRYPTOCHROME 1A”, “CRYPTOCHROME 2B-APOPROTEIN” and “CRY2AProtein” for PANTHER
424 that characterize a part of the Plant Photoreceptor CRY sequences. Finally, other PANTHER groups col-
425 lect functions from different functional classes: “(6-4) PHOTOLYASE ISOFORM A” recognizes (6-4) PL,
426 Class I CPD PL and NCRY; “CRYPTOCHROME-1” recognizes Plant PR CRY and circadian rhythms
427 transcriptional regulators, which are light independent; “SI:CH1073-390K14.1” recognises both PR and PL.
428 In particular, experimentally characterized CPF sequences show PANTHER limitations: many known (6-4)
429 PL (red subtree) are annotated as circadian regulators, Class I CPD PL is partly classified as PR instead.
430 Note also that no distinction between Class I, II, III CPD PL is evident in PANTHER classification, and
431 that sequences in the NCRY subtree are annotated as (6-4) PL while they are PRs according to us and to
432 (Emmerich *et al.*, 2020).

433 **ProfileView and the RBM approach.** The state-of-the-art neural network approach based on Restricted
434 Boltzman Machines (RBM) in (Tubiana *et al.*, 2019) relies on the generative modelling of correlations in
435 sequence alignments, it extracts biologically interpretable features but demands a particularly heavy training
436 and computational time. The RBM approach classifies the dataset of 349 WW domain sequences in 3 groups
437 (I, II/III, IV). Associated protein binding motifs have been proposed (Tubiana *et al.*, 2019).

438 The RBM approach correctly classifies 49 out of 52 functionally characterised sequences considered in
439 (Tubiana *et al.*, 2019) as described in **Table S4**. It misclassified 3 sequences, compared to ProfileView correct
440 classification of 54 out of 54 sequences. Note that the large group II/III, indistinguishable in Tubiana *et*
441 *al.*, is organised into several ProfileView subtrees of sequences known to bind to specific peptides, as shown
442 in (Otte *et al.*, 2003), providing a refined analysis of binding motifs. ProfileView tree also classifies, within
443 its subtrees, many experimentally uncharacterized WW domain sequences, largely agreeing with Tubiana’s
444 classification but not always, as seen in **Fig. 5** and **Fig. S11**.

445 In conclusion, compared to RBM (Tubiana *et al.*, 2019), ProfileView is more precise, it extracts from the
446 analysis molecular determinants underlying protein functional diversity and it is much faster. Its computa-
447 tion time is measured in hours versus days for RBM (see Methods and **Table S2**).

448 **ProfileView and CUPP.** CUPP (Barrett and Lange, 2019) is a computational approach designed to classify
449 by using short peptide sequences expected to be specific for functional characterization of carbohydrate-active
450 enzymes. In CUPP, proteins sharing the same peptide profile are claimed to share the same function.

451 The set of GH30 sequences used to validate ProfileView was also used for the evaluation of CUPP (Barrett
452 and Lange, 2019). CUPP split these sequences in 33 groups and organised them in a dendrogram (Barrett
453 and Lange, 2019) whose topology is reported in **Fig. S23A**. The dendrogram is composed of 9 subtrees
454 corresponding to the 9 CAZy subfamilies. A schematic comparison of CUPP dendrogram (Barrett and
455 Lange, 2019) and ProfileView tree is given in **Fig. S23**. Both their topologies highlight the separation of
456 the CAZy subfamilies GH30-1, GH30-2, GH30-3 and GH30-9 from the other subfamilies. ProfileView tree
457 separates further subfamilies GH30-4 and GH30-5 from the remaining ones.

458 A detailed analysis of the CAZy subfamilies indicates similar sequence organisation for the two methods.
459 For instance, CUPP organises GH30-1 sequences by splitting them in five clusters (Barrett and Lange, 2019)
460 that are easily identified in ProfileView tree, where three representative models are associated to three of
461 CUPP clusters (purple, fuchsia and dark blue in third circle of annotation in **Fig. S15**). In contrast, the
462 classification of CAZy subfamilies GH30-4 and GH30-5 (**Fig. S15**) highlights a large number of CUPP
463 clusters while ProfileView groups GH30-5 into three main subtrees and GH30-4 into one. Two of the
464 three ProfileView subtrees grouping GH30-5 are characterized by representative models. Interestingly, the
465 remaining sequences are clustered by CUPP into several clusters and no representative model is found by
466 ProfileView, indicating the difficulty of both methods to classify this group of sequences.

467 To test the general applicability of ProfileView versus CUPP, which was designed for enzyme proteins, we
468 also compared the two approaches on the CPF sequences and on the WW domain sequences. This analysis
469 highlights CUPP's limitations in handling arbitrary protein families.

470 On the WW domain sequences, CUPP does not provide any insightful classification, as **Fig. S27** shows.
471 This is probably due to the very short length of this domain, between 35 and 40aa long.

472 On the CPF family, CUPP was run using both FAD and PHR sequences. CUPP tree and its associated
473 clusters are represented in **Fig. S24** for FAD sequences (see also **Fig. S25**). CUPP: 1. groups all together
474 the CPF classes “Transcriptional regulators”, (6-4) PL and Animal PR CRY. Hence, distinguished functions
475 are shared in the same subtree. In particular, it does not distinguish light dependent from light independent
476 protein sequences; 2. does not distinguish Class I and III CPD PL; 3. places the CRYPro subtree far from
477 the remaining subtrees while, in ProfileView, CRYPro is located closer to Class II CPD PL; 4. splits the
478 CRY DASH tree into two subtrees. There is no known functional annotation for one of the subtree and,
479 therefore, it is not clear whether it is a relevant sequence split or not. ProfileView organises sequences in
480 this subtree differently.

481 Furthermore, CUPP succeeds to classify a larger number of sequences (corresponding to the leaves left

482 uncoloured in **Fig. S24**) in the CPF family compared to ProfileView that did not find, among its models,
483 sufficient confidence to include some input sequences in its tree. Viceversa, there are sequences that have
484 been classified by ProfileView and that do not belong to CUPP classification (see uncolored sequences within
485 CUPP clusters in **Fig. S24**). We also notice that, as ProfileView, CUPP: 1. groups Class II CPD PL in a
486 single subtree, and 2. distinguishes NCRY sequences.

487 When CUPP considers the whole PHR sequence, the topology of the CUPP tree (**Fig. S26B**) gets closer
488 to ProfileView topology even though CUPP keeps mixing Class I and III CPD PLs as well as light dependent
489 (6-4) PL and Animal PR CRY sequences; the NCRY subtree locates close to photolyases (**Fig. S25**); the
490 higher number of CUPP clusters fragments the functional organisation, as for instance for Class II CPD PL.

491 **Materials and Methods**

492 **Datasets used to validate the method**

493 The seven protein families used to evaluate ProfileView performance are listed in Table I (first and second
494 column). Their sets of homologous sequences have been retrieved from publicly available databases (see
495 below; see Table I, third column, for their number). All families present multiple functions. For each family,
496 a subset of sequences has been functionally classified before (see Table I, fifth column) and it has been used
497 for evaluation. Various protein sequence characteristics are reported in **Table I**, **Table S1** and **Table S2**.

498 CPF sequences were retrieved from UniProt, JGI projects (genome.jgi.doe.gov), and OIST projects
499 (marinegenomics.oist.jp). The set was constructed following two main criteria: 1. it contains CPF
500 sequences known to have a specific function according to experimental evidence reported in the literature
501 (see **Supplemental File** for bibliographical references); 2. it contains CPF sequences that span the whole
502 tree of life; they belong to 146 species, 74 classes, and 40 phyla (see **Supplemental File** for the detailed
503 list). In the text, a “CPF sequence” refers to the full length CPF sequence comprising the PHR domain,
504 including the FAD binding domain, and possibly the C- and N-terminal extensions, while a “FAD sequence”
505 refers to the FAD binding domain sequence exclusively.

506 The set of WW domain sequences was constructed by combining the datasets of natural sequences
507 analysed in (Otte *et al.*, 2003; Ingham *et al.*, 2005; Russ *et al.*, 2005; Tubiana *et al.*, 2019). 60 sequences
508 have been experimentally characterized (Otte *et al.*, 2003; Ingham *et al.*, 2005; Russ *et al.*, 2005) and the
509 remaining ones have been randomly selected, in comparable proportion, from the three sets classified in
510 Tubiana *et al* (types I, II/III, IV) (Tubiana *et al.*, 2019).

511 The set of GH30 sequences is the same used in (Barrett and Lange, 2019) (file GH30.faa provided
512 with the CUPP program v1.0.14 and containing 1803 sequences) and described in the Carbohydrate-Active
513 Enzymes database CAZy (<http://www.cazy.org/GH30.html>). It is organised in different subfamilies of the

514 CAZy classification. Some of these subfamilies are functionally classified by CAZy and some others are left
515 unclassified. We used the annotation files in (Barrett and Lange, 2019), where 721 of the 1803 sequences
516 have a mapping/label to the subfamilies from GH30-1 to GH30-9. Note that, of the 1675 sequences retained
517 for analysis by ProfileView after filtering, 695 have a label in the GH30 ProfileView tree (**Table I**).

518 The set of sequences of the HAD/ β -PGM/Phosphatase-like subgroup of the Haloacid Dehalogenase
519 (HAD) superfamily and of the three subgroups of the Radical-SAM superfamily (B12-binding domain
520 containing, Methylthiotransferase and SPASM/twitch domain containing) have been retrieved from the
521 Structure-Function Linkage Database (SFLD) (Schnoes *et al.*, 2009; Akiva *et al.*, 2014). Namely, each sub-
522 group is defined by the union of the sets of annotated sequences associated with its families in SFLD. Given
523 a subgroup, we considered all its families, even if they were represented by very few sequences, possibly only
524 one.

525 Clade-Centered Models and a multi-source functional annotation

526 Widely used search methods (Altschul *et al.*, 1997; Eddy, 2011; Remmert *et al.*, 2011) are based on a mono-
527 source annotation strategy, where a single probabilistic model (*e.g.*, a pHMM (Eddy, 1998)), generated from
528 the consensus of a set of homologous sequences, is used to represent a protein domain. The mono-source
529 strategy usually performs well for rather conserved homologous sequences, but when sequences have highly
530 diverged, consensus signals become too weak to generate a useful probabilistic representation and global-
531 consensus models do not characterize domain features properly. A *multi-source* domain annotation strategy
532 (Bernardes *et al.*, 2016), in which protein domains are represented by several probabilistic models, called
533 *Clade-Centered Models* (CCM), was implemented in CLADE (Bernardes *et al.*, 2016) and MetaCLADE
534 (Ugarte *et al.*, 2018) for genomes and metagenomes/metatranscriptomes respectively.

535 To construct CCMs (see below), we consider the *full* set of sequences S^i associated with a Pfam domain
536 D^i (Finn *et al.*, 2014) and, for each sequence $s_j \in S^i$, we construct a *clade-centered* profile HMM (CCM)
537 by retrieving a set of homologous sequences close to s_j from UniProt. Such a model displays features
538 characteristic of s_j and that might differ from other domain sequences $s_k \in S^i$. The rationale is that the
539 more s_j and s_k are divergent, the more clade-centered models are expected to highlight different features.
540 It has been shown that CCMs significantly improve domain annotation (both for full genomes (Bernardes
541 *et al.*, 2016) and for metagenomic/metatranscriptomic sequences (Ugarte *et al.*, 2018)) and, due to their
542 closeness to actual protein sequences, they are more specific and functionally predictive than the canonical
543 global-consensus approach. In this work, however, we build and use CCMs differently aiming at better
544 resolve the functional organisation of sequences within protein families, whose sequences likely share the
545 same domain architecture. In order to capture conserved motifs likely to be of functional relevance, we
546 built highly specific clade-centered models. They will likely belong to protein interaction sites, be made of

547 conserved positions on subsets of homologs, and be determinants of functional specificity.

548 **The ProfileView method**

549 A flowchart describing ProfileView pipeline is provided in **Fig. 6** and its ten main steps are explained in
550 detail below. A hands-on description of the ten steps for the CPF family is given in the **Supplementary**
551 **File**. ProfileView takes as input a Pfam domain D and a set of homologous sequences \mathcal{S} to be classified. If
552 similar Pfam domains exist (Pfam usually names them with a numerical extension, as for instance HAD and
553 HAD_2), then the user can decide to provide several alternative domains as input and construct the model
554 library \mathcal{M}_D accordingly.

555 **I. Model library construction.** To construct a library of models \mathcal{M}_D for the domain D , we considered
556 sequences from the FULL dataset in Pfam database (Finn *et al.*, 2014) and, for each sequence, we built a
557 CCM (Bernardes *et al.*, 2016) by searching in Uniclust30 (which is UniProtKB clustered at 30% identity and
558 for which a HH-blits database is provided; Mirdita *et al.* (2017)) for highly significant matches of homologous
559 sequences having at least 60% identity with the query domain sequence and covering at least 70% of it. More
560 precisely, a multiple sequence alignment is built using the command `hhblits` of the HH-suite (Remmert
561 *et al.*, 2011) (with parameters `-qid 60 -cov 70 -id 98 -e 1e-10` and database `uniclust30_2017_10`)
562 and subsequently converted into a pHMM with HMMER (Eddy, 1998) in order to perform a sequence-
563 profile comparison. Moreover, a pHMM is considered only if it is trained with a minimum number of 20
564 sequences.

565 Note that the sets of Pfam sequences in the FULL dataset might be very large (some tens of thousands
566 of sequences) and that we reduced their number to a few thousand sequences, by applying MMseq2 (at
567 <https://github.com/soedinglab/MMseq2>; the `easy-cluster` command of `mmseqs` was used with param-
568 eter `--min-seq-id`, to set the minimum sequence identity for clustering, and parameter `-c 0.8`, to consider
569 matches above this fraction of aligned/covered query/target residues) off the ProfileView pipeline, to cluster
570 close sequences together and select, from each cluster, a representative sequence from which to generate a
571 model, as above. We asked sequences in a cluster to have more than either 40 or 60% sequence identity
572 (default set at 50%) depending on the protein family, in such a way that around 3000-4000 representative
573 sequences could be identified for building the model library.

574 If several similar Pfam domains are considered, the procedure above will be applied to the Pfam sequences
575 associated with all domains.

576 **II. Sequence filtering.** After building the set of models for D , we discarded from the input set of
577 sequences \mathcal{S} , all sequences against which no domain hit was found (independently of the hit score). \mathcal{S}
578 domain annotation is carried out by considering HMMER best hits (version 3.1b2) for models in \mathcal{M}_D . Note

Figure 6: ProfileView flowchart. The ProfileView pipeline is organised in ten main steps: (I) building the model library for a domain or a few similar domains chosen by the user, (II) sequence filtering based on matching/unmatching of the models on a sequence, (III) sequence selection based on the quality of a match, (IV) filtering of models to reduce model redundancy, (V) association of two scores to each model hit, (VI) construction of the ProfileView space of sequences, (VII) dimensionality reduction of the sequence space, (VIII) construction of the ProfileView classification tree, (IX) identification of the best representative models for subtrees, (X) extraction of functional motifs from representative models. ProfileView parameters that the user can modify are highlighted in green, and those that remain fixed are highlighted in cyan.

579 that this step, based on multiple probabilistic models, is able to identify domains in divergent sequences
580 where the consensus Pfam model cannot provide a hit. For all protein families, Table I (fourth column)
581 reports the number of sequences after filtering. (See **Fig. S28A** for an illustration of sequence filtering.)

582 **III. Sequence selection.** Each CCM in \mathcal{M}_D is mapped against the set \mathcal{S} of all input sequences using
583 HMMER. Let $\mathcal{H} = \{h_{s,m} \mid s \in \mathcal{S}, m \in \mathcal{M}_D, \text{score}(h_{s,m}) > 0\}$ be the set of hits $h_{s,m}$ provided by `hmmsearch`,
584 where s is a sequence of \mathcal{S} , m is a model of \mathcal{M}_D and $\text{score}(h_{s,m})$ is the bit-score assigned to $h_{s,m}$. The
585 bit-score is a log-odds ratio score (in base two) comparing the likelihood of the pHMM to the likelihood of
586 a null hypothesis (*i.e.* an i.i.d. random sequence model). More formally,

$$\text{score}(h_{s,m}) = \log_2 \frac{\Pr(s \mid m)}{\Pr(s \mid \text{null})}$$

587 where $\Pr(s \mid m)$ is the probability of the pHMM m generating the sequence s and $\Pr(s \mid \text{null})$ is the
588 probability of s being generated by the null model (Barrett *et al.*, 1997).

589 We partitioned the hit set \mathcal{H} in three subsets $Full(\mathcal{H})$, $Overlap(\mathcal{H})$, $Partial(\mathcal{H})$, where $Full(\mathcal{H})$ contains
590 all hits that fully cover the associated model, $Overlap(\mathcal{H})$ contains all hits involving the extremes of a
591 sequence covered only partially by the associated model (this situation corresponds to an “incomplete”
592 sequence), and $Partial(\mathcal{H})$ contains all remaining hits. (See **Fig. S28B** for an illustration of the three
593 matching types.) More formally, given a hit $h_{s,m} \in \mathcal{H}$, it belongs to $Full(\mathcal{H})$ if the aligned region of m
594 to s (excluding gaps) is at least 90% of the length of m . If $h_{s,m}$ represents an overlap between s and m
595 (allowing an overhang length of at most the 10% of the sequence length) then $h_{s,m} \in Overlap(\mathcal{H})$. Otherwise,
596 $h_{s,m} \in Partial(\mathcal{H})$.

597 To eliminate potentially incomplete sequences, a sequence s is retained only if:

- 598 1. either at most the 30% of its hits belong to $Overlap(\mathcal{H})$,
- 599 2. or, at least the 50% of its hits belong to either $Full(\mathcal{H})$ or $Partial(\mathcal{H})$.

600 These two conditions have been introduced in order to take into account the fact that Pfam might also
601 contain partial sequences that could lead to the construction of very short models (that could be fully
602 aligned in potentially incomplete sequences). We refer to the reduced set of sequences as \mathcal{S}^* .

603 **IV. Data driven selection of models based on sequence best matching.** In order to restrict the
604 analysis to a reduced set of models that remains representative of \mathcal{M}_D , we kept only those models that
605 achieve one of the k best scores for at least one sequence of \mathcal{S}^* , for $k = 3$ (default). The rationale of this
606 model filtering is to get rid of “noisy” models and, at the same time, significantly reduce the size of \mathcal{M}_D , from
607 some thousands down to a few hundreds. We refer to the reduced set of models as \mathcal{M}_D^* . k is a parameter
608 that can be set by the user.

609 **V. Association of two ProfileView scores to model hits: the normalized bit-score and the**
610 **normalized weighted bit-score.** Let L_s be the number of positions in a sequence s that match to a
611 model m in a sequence/model alignment (that is, no gap is considered in the counting). Given a hit $h_{s,m}$
612 we define the following two scores for it:

- 613 • a normalized bit-score $ns(h_{s,m}) = \frac{score(h_{s,m})}{L_s}$;
- 614 • a normalized weighted bit-score $nws(h_{s,m}) = \frac{Wscore(h_{s,m})}{L_s}$, where $Wscore(h_{s,m})$ is the sum of bit-scores
615 over the positions in the sequence-profile alignment where the bit-score is greater than 3 (that is, the
616 positions where m and s strongly agree). More formally, let $\sigma(s_i, m_j) = \log_2 \frac{e(s_i, m_j)}{bg(s_i)}$ be the log-odds
617 ratio of a residue s_i being emitted from a match state m_j with emission probability $e(s_i, m_j)$ and with
618 null model background frequency $bg(s_i)$, defined by HMMER during the model construction and differ-
619 ing between amino acids (Eddy, 1998). Given the list $\langle (s_{i_1}, m_{j_1}), \dots, (s_{i_K}, m_{j_K}) \rangle$ of the aligned residues
620 of s against the model states of m and such that the posterior probability, computed by HMMER, of
621 each aligned pair is greater than 75%, we define $Wscore(h_{s,m}) = \sum_{z=1}^K \sigma(s_{i_z}, m_{j_z})$.

622 Both scores are computed for all hits $h_{s,m}$ and used to construct the ProfileView space of sequences.

623 **VI. The construction of a ProfileView space of sequences.** For each sequence $s \in \mathcal{S}^*$, we construct
624 a vector v_s , where the dimension of v_s is $2|\mathcal{M}_D^*|$ and $|\mathcal{M}_D^*|$ is the number of models in \mathcal{M}_D^* . The vector v_s
625 contains the pairs of values $ns(h_{s,m})$ and $nws(h_{s,m})$, for each $m \in \mathcal{M}_D^*$. If a model m does not have a hit
626 on the sequence $s \in \mathcal{S}^*$, then we assume that $h_{s,m} \notin \mathcal{H}$ and let $ns(h_{s,m}) = 0$ and $nws(h_{s,m}) = 0$. Hence,
627 we say that the ProfileView space \mathcal{PV} is a $2|\mathcal{M}_D^*|$ -dimensional space, where each dimension is associated
628 with either the normalized bit-score or the normalized weighted bit-score for some model $m \in \mathcal{M}_D^*$. Each
629 sequence is a point in \mathcal{PV} and its position reflects the proximity of the sequence to CCMs in \mathcal{M}_D^* .

630 **VII. PCA and dimensionality reduction for ProfileView space of sequences.** After constructing
631 the ProfileView space \mathcal{PV} for the sequences $s \in \mathcal{S}^*$, Principal Component Analysis (PCA) is performed to
632 reduce its number of dimensions. More precisely, \mathcal{PV} is reduced to a p -dimensional space \mathcal{PV}^* , where p is
633 the minimum number of principal components that explain the $c\%$ of variance for the set \mathcal{S}^* . By default,
634 $c = 99\%$. This value should decrease the number of dimensions to a few dozens. If a protein family is
635 characterised by a large diversity of representative sequences, the user may have to loosen the constraints
636 on variance by setting c to smaller values. c is a parameter that can be set by the user.

637 **VIII. The ProfileView tree construction.** Sequences are clustered in \mathcal{PV}^* using a hierarchical agglomer-
638 ative strategy. Namely, we considered the Euclidean distance between vectors and Ward's minimum variance
639 method for merging clusters. The logic of this criterion is to select, at each step, the pair of clusters that
640 minimize the total variance within the cluster after the merging. Starting from all clusters being singletons,

641 this bottom-up algorithm completes in $|\mathcal{S}^*| - 1$ agglomerative steps and allows to represent clusters in a
642 hierarchical way and to define a rooted tree. More precisely, it produces a binary tree where each internal
643 node defines a cluster of two or more elements (according to the chosen merge criterion). Moreover, in such
644 a tree, the distances/dissimilarities between the merged clusters are encoded as edge weights.

645 **IX. Association of representative models to ProfileView subtrees.** To better explore subtrees in the
646 ProfileView tree, potentially associated with known functions, we associated a *representative model* to the
647 sets of sequences that label their leaves. Intuitively, a representative model separates a subset of sequences \mathcal{C}
648 from the rest of the sequences of the tree (this set is designated $\mathcal{S}^* \setminus \mathcal{C}$) in the ProfileView space \mathcal{PV}^* . Given
649 a model m in the library, let us call \mathcal{C}_m^* the maximal subset of \mathcal{C} where the model assigns higher scores to
650 sequences in \mathcal{C}_m^* than to sequences in $\mathcal{S}^* \setminus \mathcal{C}$. This must apply to at least one of the metrics – ns and nws
651 – which define \mathcal{PV}^* (see step III). For each model m in the library, we compute \mathcal{C}_m^* and choose the model
652 with a \mathcal{C}_m^* of largest cardinality as the *representative model* of \mathcal{C} . If two models have the same maximum
653 cardinality, we choose the model m that provides the best separation, i.e. the model that maximizes the
654 distance between the centroids of the sets \mathcal{C}_m^* and $\mathcal{S}^* \setminus \mathcal{C}$ (again, computed according to the ns and nws
655 metrics). If \mathcal{C} is the set of sequences of a subtree T of the ProfileView tree (which is not the entire tree), then
656 a *representative model* m for \mathcal{C} is associated with the root of T when the following two conditions are met:
657 1. \mathcal{C}_m^* includes at least half of the sequences in \mathcal{C} and 2. \mathcal{C}_m^* contains at least one sequence from each of the
658 child subtrees of T . Note that a node in the ProfileView tree might be left without a representative model.
659 When ProfileView returns a representative model for a node of the tree, it also returns a list of suboptimal
660 models covering either the same amount of sequences $|\mathcal{C}_M^*|$ or 90% of $|\mathcal{C}|$.

661 **X. Motifs extraction from representative models.** A motif extracted from a representative model is
662 the set of all amino acids characterizing well-conserved columns (*i.e.* match states) in the sequence alignment
663 associated with the model, according to the `hhblits`' definition. That is, given a column of the multiple
664 sequence alignment related to the model, an amino acid is *well-conserved* if it occurs with a probability
665 ≥ 0.6 before adding pseudo-counts and including gaps in the fraction count.

666 Parameters used in ProfileView analysis of the seven protein families

667 For all protein families, the domain(s) considered for model construction, their accession code and the number
668 of constructed models are reported in **Table I**. For the model construction, representative sequences for
669 FAD and GH30 were retrieved from Pfam v31 while for all other domains, we used Pfam v32. For the three
670 families, Glycoside Hydrolase family 30 (GH30), HAD/ β -PGM/Phosphatase-like and B12-binding domain
671 containing, Pfam contains two similar domains (see Table I, sixth column) and we used Pfam sequences from
672 both of these domains, we clustered them and built the associated models. For the three families, using two
673 domains instead of one improves the classification slightly.

674 ProfileView was run with the same default parameters $k = 3$ and $c = 99\%$, for all protein families in
675 Table I, with the exception of the WW domain, which is characterised by a wide variability of sequences,
676 that run with $k = 5$ and $c = 80\%$ (see steps IV and VII). For WW domains, note that with $c = 80\%$, we have
677 obtained a space of 11 dimensions, against 206 dimensions obtained with a threshold of $c = 99\%$, starting
678 from a total of 2488 dimensions. Also, the number of best matching models increased to $k = 5$ allowed us to
679 obtain 1244 models versus 845 obtained with $k=3$. The idea being that when the dataset of sequences to be
680 classified is very diversified, as for the WW domain family, the number of models should be large (> 1000)
681 to explain diversity.

682 For the SPASM/twitch domain containing family subgroup, we performed two independent analyses, one
683 based on the Radical-SAM domain and the other based on the SPASM domain. This is because all the
684 original sequences contained the Radical-SAM domain but not all contained the SPASM domain.

685 Motifs graphical representation

686 Model logos were built using the python package of Weblogo (Crooks *et al.*, 2004) (version 3.7) which allowed
687 us to easily export sequence logos (Schneider and Stephens, 1990). Amino acids are colored according to
688 chemical properties: neutral polar amino acids (G, S, T, Y, C) show in green, acidic polar (Q, N) violet,
689 positively charged (K, R, H) blue, negatively charged (D, E) red, and hydrophobic (A, V, L, I, P, W, F, M)
690 black.

691 The graphical representation of a motif associated with some representative model was augmented by
692 extra information helping to easily compare the motif across representative models. Namely, we highlighted,
693 by a coloured “dot”, positions in it found to be well-conserved in other representative models. Given a
694 reference model M_r and a query model M_q , a dot is put under a well-conserved column of M_r , if there exists
695 a column in the query model M_q : 1. aligning in `hhblits` with a score greater than +1.5 (*i.e.* fairly similar
696 amino acid profiles) and posterior probability greater than 0.8; 2. containing a most conserved amino acid
697 which is the same as in M_r and is also well-conserved. A circled dot indicates an aligned column in M_q
698 satisfying 1 but not 2. This means that the most conserved amino acid in M_r shows $< 60\%$ frequency in
699 M_q . Note that, in this case, M_r and M_q might display different most conserved amino acids.

700 It is important to notice that given two models and a position, the score assigned to that position in
701 the `hhblits` pairwise alignment of the models depends on the reliability of the query-template alignment
702 (<https://github.com/soedinglab/hh-suite/wiki>). Depending on which one of the models is considered
703 as a template, the scores assigned to the same position might vary (the confidence values are obtained
704 from the posterior probabilities calculated in the Forward-Backward algorithm of `hhblits`). In particular,
705 `hhblits` is warning that the confidence score for an aligned position depends on the confidence on the
706 alignment of the close by region. As a consequence, the alignment score of certain conserved position might

707 decrease because of the presence of a very variable region in their vicinity, possibly containing gaps. This
708 explains why, for aligned positions of two motifs, we might miss to indicate related positions or we might
709 display different color dots. An example of missing related positions is illustrated by position 102 in the
710 NCRY motif and position 103 in the plant PR CRY motif of CPF. The two motifs clearly diverge within
711 the region just following positions 102/103, justifying a difficult model alignment and a low confidence score
712 for 102/103. A second example, illustrating the asymmetry of the coloured dots, is position 102 in the
713 NCRY motif aligned with position 95 in CRY Pro. While the CRY Pro motif records the coloured dot for a
714 matching with NCRY, this is not true for the NCRY motif. Indeed, while the two positions align together
715 with a confidence score of 0.8 for the CRY Pro model taken as a template, they also align together when
716 the NCRY model is taken as the template but with a confidence score dropping at 0.6.

717 **Phylogenetic tree construction for CPF, FAD and WW sequences**

718 The multiple sequence alignments of CPF sequences and FAD sequences were computed using MUSCLE
719 version v3.8.31 (Edgar, 2004), and were then trimmed using trimAl version 1.4.rev22 (Capella-Gutiérrez
720 *et al.*, 2009) with a gap cutoff of 0.01 (*i.e.* columns containing more than 99% of gaps were removed). Then,
721 for each sequence alignment, we selected the best evolutionary model using ProtTest (version 3.4.2) (Darriba
722 *et al.*, 2011). More precisely, the evolutionary model best fitting the data was determined by comparing the
723 likelihood of all models according to the Akaike Information Criterion (AIC). The model optimisation of
724 ProtTest was run using a maximum-likelihood-tree strategy and the tree generated for the best-fit model
725 (VT+G+F) was considered as input for the construction of the final phylogenetic tree (with parameter $\alpha =$
726 1.061). In particular, the construction of a maximum-likelihood phylogenetic tree has been carried out
727 with PhyML 3.0 (Guindon *et al.*, 2010) that optimized the output tree with Subtree-Prune-Regraft (SPR)
728 moves and considering the SH-like approximate likelihood-ratio test. Finally, branches with a support value
729 smaller than 0.5 were collapsed. The phylogenetic tree for the set of homologous CPF sequences used to
730 validate ProfileView is reported in **Fig. S3** and contains 307 leaves corresponding to the 307 CPF sequences
731 containing the FAD binding domain. The phylogenetic tree for the set of 307 FAD sequences is reported in
732 **Fig. S4**.

733 The procedure used to generate the phylogenetic tree for WW domain sequences is the same as the one
734 used for CPF and FAD sequences. The best-fit model (computed with ProtTest) is RtREV+I+G, with
735 parameters $\alpha = 1.647$ and $p - inv = 0.028$.

736 Phylogenetic and ProfileView trees have been generated with iTOL (Letunic and Bork, 2019).

737 Output files of ProfileView

738 ProfileView produces several output datasets: the model library, the ProfileView tree, the list of representa-
739 tive models associated with internal nodes of the tree.

740 Also, ProfileView provides to the user the possibility to choose a list of representative models to be
741 compared. The first model of this list is considered as a reference model. A first output describes and
742 provides the logo reporting all conserved positions together with a list of coloured dots (possibly circled)
743 obtained after a pairwise comparison of a model in the list with the reference model (see Methods above;
744 see for example **Fig. 1D**). A second output describes and provides the logo reporting an intermediate
745 representation of the positions in the reference model, namely reporting all conserved positions in the
746 associated motif and all positions that are not conserved in the reference model but that are conserved in
747 some other model in the list.

748 1.1 Comparison with other tools

749 CUPP (Barrett and Lange, 2019) and PANTHER (Mi *et al.*, 2012, 2013) have been used for comparison.
750 CUPP v1.0.14 was run with `CUPPclustering.py` and parameter `-cluster` to execute the clustering (<http://www.bioengineering.dtu.dk/CUPP>). The PANTHER HMM library version 15.0 and the pantherScore2.2
751 tool (scoring protein sequences against the library) were retrieved at <http://www.pantherdb.org>. We used
752 `pantherScore2.2.pl` with parameters `-l [PANTHER15.0_library] -D B -n`, where `-D B` allows to visualise
753 the best hit in the output and `-n` allows to visualize family and subfamily names in the output.

755 Evaluation

756 For each protein family, we considered functionally characterised pools of sequences collected from the
757 literature and classified them in groups with ProfileView. To evaluate what proportion of sequences with a
758 specific function is correctly classified by ProfileView, we used the Recall measure, defined as $TP/TP+FN$,
759 where TP is the number of sequences that ProfileView classifies correctly and FN is the number of sequences
760 that it classifies in the wrong group. The idea is to evaluate in which manner ProfileView captures as many
761 positives as possible.

762 Computing time

763 The most costly computational part of the pipeline is the construction of the probabilistic models for a
764 protein sequence. The program was tested using 16 threads on a single machine equipped with an Intel
765 Xeon E5-2670 CPU running at 2.60GHz, with 128 GB of RAM, and a Linux operating system (CentOS
766 release 6.5). **Table S2** summarizes, for each protein family, the time complexity for the model library
767 construction and the classification step. The time used for the model library construction depends on the

768 number of models and the length of the domain. Once a library is constructed, it can be used for the analysis
769 of different protein families. Note that the same library constructed for the Radical SAM domain was used
770 for both the analysis of the Methylthiotransferase family and the SPASM/twitch domain containing family.

771 Note that, for the WW domain family, (Tubiana *et al.*, 2019) indicates about 1-2 days of computing time
772 on an Intel Xeon Phi processor with 2×28 cores to run RBM analysis. ProfileView classifies this family in
773 less than 9 hours (**Table S2**).

774 **Implementation and software availability**

775 ProfileView has been developed and tested under a UNIX operating system, using Bash, Python, and R
776 scripts. It exploits GNU parallel (Tange, 2018), if available on the system, in order to perform some jobs
777 in parallel. It is implemented in three main parts carrying out the following modules of the pipeline:
778 the construction of a single-domain model library, the generation of the ProfileView tree along with its
779 representative models, the comparison of selected representative models and the identification of conserved
780 positions/motifs. ProfileView is available at <http://www.lcqb.upmc.fr/profileview/> under the version
781 2.1 of the CeCILL Free Software License.

782 **Data accessibility**

783 The set of sequences used in the analysis and the model libraries, distance trees, ProfileView trees generated
784 and discussed in the article (Cryptochrome/Photolyase Family, the WW domain family, the glycoside hy-
785 drolase enzymes family GH30, the four enzyme superfamilies of the Structure-Function Linkage Database)
786 are available at <http://www.lcqb.upmc.fr/profileview/>.

787 **Discussion**

788 The availability of large quantities of (meta)genomic data is allowing for a deeper exploration of living or-
789 ganisms and of the processes underpinning their genetic, phylogenetic and functional diversification. Com-
790 putational approaches, able to highlight these diversities and to identify what is functionally new within the
791 realm of sequence information, will make the first fundamental step in the discovery of new candidates to
792 be experimentally tested for their functional activity. Moreover, due to the huge quantity of sequences to
793 be acquired in years to come (1 zetta-bases/year are expected in 2025 (Stephens *et al.*, 2015)), there will be
794 no more way to look into this mass of data with an “expert eye” and computational approaches will play a
795 key role on the extraction of novel information and in functional classification.

796 Today, we can characterise homologs based on their similarity through distance measures modelling the
797 evolution of the entire sequences. However, as shown here and elsewhere (Schnoes *et al.*, 2009; Mi *et al.*, 2012;
798 Akiva *et al.*, 2014; Barrett and Lange, 2019), this computational approach is insufficient to provide insights

799 on protein functional activities, and a large number of sequences remain not yet functionally annotated.
800 Some of these protein families, like the seven families discussed in this study, are extremely important in
801 medicine, biology, environmental science and biotechnology due to their key roles in cancer biology, DNA
802 repair, drug delivery strategies, chronobiology and photobiology, specific enzymatic reactions, the formation
803 of protein-protein interaction networks, optogenetics. Thanks to their key role, for decades now, experiments
804 have accumulated a huge amount of functional information that we used to validate the ProfileView approach.
805 ProfileView functional organisation of these seven families agrees with experimental evidence.

806 ProfileView highlights that protein functional classification depends on a non-linear contribution of many
807 probabilistic models and that conserved patterns in sequences are not sufficient alone to discriminate diver-
808 sified functions of complex protein families. This change of perspective in functional classification, underlies
809 the complexity of the question and explains why this problem is wide open today despite the clear interest in
810 classifying protein families that have been amply studied in molecular biology, like transporters, signalling,
811 transcription factors.

812 By constructing multiple probabilistic profiles characterising different conserved motifs in homologous
813 domain sequences, ProfileView captures functional signals and, by combining them, is able to successfully
814 classify large datasets. The main advantages of ProfileView approach compared to those developed before are
815 as follows: (i) it is alignment-free and avoids errors due to the difficulty of comparing distant homologues; (ii)
816 several probabilistic models represent more precisely than a single consensus models the functional variability
817 of protein families; (iii) large quantities of data are not needed to learn features and run the classification;
818 (iv) functional annotation of many sequences does not need to be known to explore with precision the
819 space of sequences and classify them; (v) it is a general approach applicable to proteins of arbitrary length
820 and function. Moreover, once a domain library is constructed, ProfileView is computationally efficient in
821 screening very large sets of homologous sequences in a reasonable time.

822 ProfileView demonstrated to discover potentially interesting CPF proteins whose function could be ex-
823 perimentally tested with the purpose of enlarging our understanding of the mechanisms exploiting light
824 to perform functional activities in natural environments. These proteins are of interest for biotechnology
825 and any computational approach to highlight them is desired. It also organised the WW domain family in
826 subtrees of sequences, corresponding to a large spectrum of differences in binding affinity to various ligands,
827 which have been experimentally observed. It demonstrates that a large variety of sequence motifs covers
828 this spectrum and it identifies these motifs. It could classify protein superfamilies in the manually curated
829 CAZy and SFLD databases by accurately identifying differences in their multiple enzymatic reactions. Com-
830 pared to Tubiana *et al* (Tubiana *et al.*, 2019), a computational approach also based on sequence analysis,
831 it describes differences among binding motifs in much greater detail, opening new avenues in the discovery
832 of alternative binding patterns in protein-protein interaction networks. It has been compared favorably to

833 other classification tools like PANTHER and CUPP, on the CPF, the WW domains and the GH30 family
834 classified in the Carbohydrate-Active Enzymes database CAZy.

835 On the methodological side, ProfileView addresses the problem of extracting biological information on
836 protein families from the huge space of natural sequences, and the sampling of distant sequences could be
837 realised using different distance measures. This is an important direction of investigation possibly leading
838 to more refined biological information extracted from sequences.

839 From the algorithmic point of view, ProfileView is surprisingly simple compared to the Restricted Boltz-
840 mann Machines (RBM) model used in (Tubiana *et al.*, 2019) to classify WW domain homologs. RBM,
841 is a generative stochastic (single layer) artificial neural network that learns collective modes by extract-
842 ing short sequence motifs from sets of sequences based on correlation patterns among alignment positions.
843 These motifs might reveal structural, functional and phylogenetic features and they are used to define a
844 representation space where to classify sequences. RBM generative nature makes training challenging by an
845 algorithmic point of view since it requires intensive sampling from large training sets. In contrast, Profile-
846 View constructs probabilistic profiles from close neighbours of distant homologous sequences (demanding a
847 very small number of sequences, a minimum of 20) in sequence space, making no use of positional correla-
848 tions nor of their generative modelling. Its probabilistic models encode conserved patterns ignoring those
849 parts of the homologous sequences appearing variable (see discussion on the two CPF sequences U5NDX3
850 and R7UL99 above). The number of models is not a restriction for the construction of the classification
851 space. A possible direction of investigation is the design of multiple layers (of models) for an architecture
852 that analyses finer motifs as well as proteins comprising multiple domains.

853 The fine understanding of functional mechanisms might need more sophisticated computational ap-
854 proaches than ProfileView. For instance, for CPF classification which is based on the FAD binding domain,
855 ProfileView highlights functional differences between large classes of CPF sequences, helping to model the
856 proximity between these classes with an appropriate identification of a functional tree topology. To find
857 functional differences within classes and to anticipate the existence of a double function (see **Fig. S1**), the
858 entire CPF sequence might be necessary, possibly because of the interaction between domains which might
859 have functional consequences as highlighted in (Rosensweig *et al.*, 2018).

860 Last, even if ProfileView has been applied here to the classification of entire protein sequences, it can
861 handle metagenomics sequences as well. In this respect, it is important to highlight that the majority of
862 metagenomics and metatranscriptomics data come from organisms that cannot be cultured and that will,
863 possibly, never be isolated. Hence, conceptual new approaches to explore their biology in complex ecosystems
864 is desperately needed. ProfileView allows to increase knowledge on the biology of organisms whose ecological
865 role has been recognised (*e.g.* marine microbes) but that are still not accessible to functional investigations,
866 opening a new avenue to functional exploration.

867 **Availability of data and materials**

868 The set of sequences for CPF, FAD, WW domain, Glyco-hydro-30 and Glyco-hydro-30-2 for GH30, HAD
869 and HAD_2 for Haloacid Dehalogenase, B12-binding and B12-binding_2 for B12-binding domain containing,
870 Radical SAM for Methylthiotransferase and SPASM/twitch domain containing subgroups, and SPASM
871 for SPASM/twitch domain containing subgroup, model libraries, phylogenetic trees, ProfileView trees are
872 available at <http://www.lcqb.upmc.fr/profileview/>.

873 **Competing interests**

874 The corresponding author declares that there are no financial nor non-financial competing interests on behalf
875 of all authors.

876 **Funding**

877 LabEx CALSIMLAB (public grant ANR-11-LABX-0037-01 constituting a part of the "Investissements
878 d'Avenir" Program ANR-11-IDEX-0004-02) (RV); the Institut Universitaire de France (AC); access to the
879 HPC resources of the Institute for Scientific Computing and Simulation (Equip@Meso project - ANR-
880 10-EQPX- 29-01, Excellence Program "Investissement d'Avenir") (AC); Fondation Bettencourt-Schueller
881 (Coups d'Élan pour la Recherche Française-2018) (AF); LabEx DYNAMO (public grant ANR-11-LABX-
882 0011-01) (AF).

883 **Authors' contributions**

884 RV and AC conceived and designed the experiments. RV performed the experiments. EL performed the
885 structural analysis of CPF classes. RV, JPB, AF and AC analyzed the data. AC, RV, JPB and AF wrote
886 the paper. All authors read and approved the final manuscript.

887 **Acknowledgements**

888 We thank Simona Cocco and Jérôme Tubiana for providing to us the dataset of WW sequences used in their
889 study.

1116 SUPPLEMENTARY FILE

1117 1. Functional diversification of CPF

1118 Photolyases are photoactive enzymes that bind DNA and use blue light to mend two different types of
1119 UV-induced DNA damage, either ss/dsDNA cyclobutane pyrimidine dimer (CPD) or (6-4) pyrimidine-
1120 pyrimidone photoproducts, and are thus classified as either CPD or (6-4) photolyases. Moreover, some
1121 photolyases such as CRY-DASH can only bind and repair ssDNA CPD. The weaker DNA photolyase activ-
1122 ity of CRY-DASH has been reported as a consequence of lower DNA binding affinity than CPD photolyase
1123 (Sato *et al.*, 2018). Cryptochromes (CRY) do not bind DNA and are mainly photoreceptors (PR) (specifically
1124 noted PR CRY in the following) involved in many biological responses to light (*e.g.* photomorphogenesis, en-
1125 trainment of the circadian clock). However, some CRYs are also light-independent transcriptional regulators
1126 taking part in the central circadian oscillator generating biological rhythms.

1127 In the last decade, new CPF variants, exhibiting different photobiological properties or functions, have
1128 been discovered, changing current views on their evolution (Jaubert *et al.*, 2017) and functional diversification
1129 (Coesel *et al.*, 2009; Heijde *et al.*, 2010; Fortunato *et al.*, 2015; Essen *et al.*, 2017). The initially proposed
1130 functional separation between CRYs and PLs has gradually started to vanish, as there are now several
1131 examples of CPF members exhibiting both functions (Coesel *et al.*, 2009; Heijde *et al.*, 2010; Franz *et al.*,
1132 2018). Some CPF members have even been used for optogenetic applications (Ozkan-Dagliyan *et al.*, 2013;
1133 Liu *et al.*, 2012) or proposed as magnetoreceptors (Rodgers and Hore, 2009).

1134 Although a lot of experimental progress has been made, CPF functions could not be anticipated by the
1135 analysis of domain organisation due to a very simplified architecture of the CPF sequences, nor by structural
1136 properties due to the high similarity of their protein structures, nor by primary protein sequences. Tools
1137 employed for the phylogenetic reconstruction of this family (Chaves *et al.*, 2006; Lucas-Lledó and Lynch,
1138 2009; Mei and Dvornyk, 2015; Ozturk, 2017) did not allow to resolve different functions (*e.g.*, light-dependent
1139 DNA photolyases and light-independent transcriptional regulators) or to anticipate the function of new CPF
1140 sequences.

1141 2. ProfileView algorithm applied to the CPF family

1142 A hands-on description of our methodological approach is provided here for the analysis of the cryp-
1143 tochrome/photolyase family (CPF). ProfileView bases the analysis on the FAD binding domain, occurring
1144 in all CPF sequences, and considers the set \mathcal{S}_{CPF} of 397 CPF sequences spanning the whole phylogenetic
1145 tree, of which 69 are functionally characterized CPF homologs and the remaining ones are known function-
1146 ally uncharacterised sequences. The ProfileView pipeline, comprising ten main steps, is illustrated by the
1147 flowchart in **Fig. 6**.

1148 **I. Model library construction.** ProfileView constructs a library, \mathcal{M}_{FAD} , of probabilistic models (Eddy,
1149 1998) for the *FAD binding domain of DNA photolyase* from Pfam version 31 (accession code PF03441),
1150 due to its functional importance for CPF activity (**Fig. 1** and **Fig. 6**). More in detail, we **considered** all
1151 4615 sequences which belong to the FULL alignment in Pfam. For each one of them, a CCM has been
1152 constructed with the command mentioned above. Finally, our model library \mathcal{M}_{FAD} for the FAD-binding
1153 domain comprises 3735 CCMs, because for some sequences we could not collect a minimum of 20 homologs.
1154 The pipeline for \mathcal{M}_{FAD} construction is depicted in **Fig. 1A**.

1155 The set of Pfam sequences used to construct the ProfileView’s model library for CPF is mainly different
1156 from the set of classified sequences: among the 240 models taken into account for the classification of
1157 the 307 sequences, just 17 of these models were built from a (Pfam) sequence in \mathcal{S}_{CPF} and only one is a
1158 representative model (for the (6-4) PL subtree) in the ProfileView tree. Moreover, the average identity and
1159 similarity (based on pairwise alignments) between the set of 307 sequences to classify and the set of the 240
1160 sequences generating the models are 26.35% and 36.73%, respectively.

1161 **II. Sequence filtering.** After building \mathcal{M}_{FAD} , we discarded from \mathcal{S}_{CPF} all sequences against which we
1162 were not able to find any domain hit (independently of the hit score). \mathcal{S}_{CPF} domain annotation was carried
1163 out by considering HMMER best hits (version 3.1b2) for all models in \mathcal{M}_{FAD} . An a posteriori phylogenetic
1164 analysis of the original set of CPF sequences has been carried out with RAxML version 8.2.11 (with parameter
1165 `-m PROTGAMMAAUTO`). We observed that the set of discarded sequences, presenting no FAD binding domain
1166 match, correspond to long branches in the tree (see **Fig. S28A**). This preliminary filter led us to consider
1167 a set of 386 CPF sequences over the 397 we started with.

1168 **III. Sequence selection.** The 386 CPF sequences are then selected further by considering the full set of
1169 models and evaluating the strength of their hits against the sequences. This testing is intended to discard
1170 sequences that end with just a fragment of the domain (see **Fig. S28B**). The corresponding hits are expected
1171 to be very weak and this concerned 79 CPF sequences. We remained with 307 sequences corresponding to
1172 the leaves of the ProfileView tree. We refer to this reduced set as $\mathcal{S}_{\text{CPF}}^*$.

1173 **IV. Models filtering.** The rationale of this model filtering is to get rid of “noisy” models and significantly
1174 reduce the size of \mathcal{M}_{FAD} down to a few hundred models. For the 307 CPF sequences, we extracted the three
1175 models in \mathcal{M}_{FAD} that best match the sequence and make the union of all of them. Many CPF sequences
1176 are best matched by the same models and the final set is comprised of 240 models that best identify the
1177 presence of the FAD binding domain in CPF sequences. We refer to this reduced set as $\mathcal{M}_{\text{FAD}}^*$.

1178 **V. Association of two ProfileView scores to model hits: the normalized bit-score and the**
1179 **normalized weighted bit-score.** To each hit, between a sequence s in $\mathcal{S}_{\text{CPF}}^*$ and a model m in $\mathcal{M}_{\text{FAD}}^*$, we
1180 applied the definitions of the two scores given in Methods and used all the scores to represent the sequence
1181 s as a vector of 480 dimensions.

1182 **VI. The construction of a ProfileView space of sequences.** This step contains the central idea of the
1183 ProfileView method: each CCM is matched to each sequence to be classified and the scores of the hits (see
1184 columns of real numbers in **Fig. 1B**) will provide a description of how close the model is to each sequence.
1185 In its turn, a sequence can be represented by how close all models are to it through a vector of scores (see
1186 rows of real numbers in **Fig. 1B**). In this way, we define a representation space of sequences that does not
1187 reflect sequence similarity but, instead, the closeness of each sequence to each model. Since a match of a
1188 model is evaluated by two scores (see V), the space will be a 480-dimensional space and each sequence will
1189 be a point in the space.

1190 **VII. PCA and dimensionality reduction for ProfileView space of sequences.** For this step, we
1191 used the parameter $c = 99\%$. From 480 dimensions, the reduction produced a space of 37 dimensions.

1192 **VIII. The ProfileView tree construction.** This step classifies the set of protein sequences in the 37-
1193 dimensional space. For the generation of our ProfileView tree, we use a hierarchical clustering algorithm
1194 which allows to build a tree that groups together the 307 sequences. The ProfileView tree built for the CPF
1195 sequences is depicted in **Fig. S1**, where internal colours are identified by representative models (see below)
1196 and external strips are associated with known functions (according to the literature, see **Supplemental**
1197 **File** for the detailed list of publications).

1198 **IX. Association of representative models to ProfileView subtrees.** We associate several represen-
1199 tative models to subtrees of the ProfileView tree following the procedure detailed in Methods. **Fig. S1**
1200 indicates which nodes of the CPF tree are represented by a model.

1201 **X. Motifs extraction from representative models.** We extracted from each representative model
1202 in **Fig. S1** associated with the colored functional subtrees, their corresponding functional motifs. They
1203 represent the specificity of the sequences within each subtree.

1204 **3. Identification of known key residues by comparison of representative** 1205 **motifs in CPF**

1206 The comparison of ProfileView motifs' positions versus experimentally characterized positions is reported in
1207 our manually curated list "CPF_mutants_used_for_validation.xlsx". **Table S3** indicates how many Profile-
1208 View positions are validated by current experimental evidence.

1209 Some positions in a motif might be conserved also in other motifs (corresponding to other subtrees), but
1210 some positions are motif specific, as illustrated by the colored dots in the logos of **Fig. S5** and **Fig. S6** (see
1211 Methods). A number of observations are given below, especially for those highly specific positions that have
1212 not been reported in the literature before.

1213 **The transcriptional regulators motifs.** As expected, most of the positions in motif #1, associated with
1214 the light-independent transcriptional regulator sequences (**Fig. 4A** and yellow subtree in **Fig. S1**), are
1215 conserved in other subtrees as well, notably (6-4) PL and animal PR CRY, because of the proximity of these
1216 subtrees in the phylogenetic tree. Highly conserved positions in most, if not all, models are clearly identified
1217 as highly conserved also in the Pfam model (**Fig. S7**). However, four positions (L6, N38, L42 and K44 in
1218 **Fig. 4A**) appear to be specific to light-independent transcriptional regulators. Three residues belong to the
1219 same helix ($\alpha 12$) and two of these positions (N38, K44) are known to belong to the interaction site with
1220 a partner and to the ubiquitination site (Hirano *et al.*, 2013; Schmalen *et al.*, 2014). The two remaining
1221 conserved positions (L6, L42), at the best of our knowledge, have not been identified before and open ways to
1222 new investigations. Similar considerations can be drawn on motif #2 associated with the light-independent
1223 transcriptional regulator sequences (**Fig. 4B**).

1224 **The (6-4) photolyase motif.** The (6-4) photolyase motif generated by ProfileView highlights the highly
1225 specific amino acid L115 which interacts with DNA and belongs to the site of the damage DNA strand
1226 binding (**Fig. 4C**; see its specificity in **Fig. S5**). This position has not been discussed previously in the
1227 literature.

1228 **Comparison of classes I and III CPD PL motifs.** By comparing the motif representing classes I and
1229 III CPD PL with those representing either class I CPD PL or class III CPD PL (see **Fig. S29**), we notice
1230 that there is almost no amino acid which is motif-specific among the three models. The strong closeness
1231 between motifs of class I and class III agrees with their shared function. We especially notice the conserved
1232 amino acids involved in CPD lesion binding sites such as W7, N71, M75, W114 and possibly F129 and Q134
1233 (where numbers refer to the motif accounting for both classes I and III CPD PL; see "Class I & III CPD
1234 PL" motif and structure in **Fig. S29**), or those involved in FAD binding or FAD binding pocket such as
1235 R74, D102, D104, N108 (directly involved in the proton transfer to the FAD; see "Class I & III CPD PL"
1236 motif and structure in **Fig. S29**; see **Supplemental File**). This example demonstrates that the analysis

1237 of the different motifs at different nodes might be used to deduce common functions. However, it is possible
1238 to extract some differences among the two motifs, where specific amino acids such as W60 (for class III
1239 CPD PL) versus Y56 (for class I CPD PL) were suggested to make an alternative electron transfer pathway
1240 possibly important in some specific condition (Scheerer *et al.*, 2015). Other interesting differences are W29,
1241 D63 and T64 from class III CPD PL which have been identified as interacting with the MTHF in a specific
1242 binding site of MTHF from class III CPD PL (Scheerer *et al.*, 2015).

1243 **Comparison of classes I and III CPD PL and plant PR CRY motifs.** Classes I and III CPD PL
1244 and plant PR CRY are well-studied families in terms of function and molecular mechanisms, and present
1245 numerous specific mutants leading to a loss of function. Remarkably, by crossing the functional charac-
1246 terisation of specific residues in the collections of mutants described in the manually curated list with our
1247 representative models of classes I and III CPD PL and plant PR CRY, we could validate 26 and 35 of the
1248 ProfileView positions from the 33 and 47 positions in the list, respectively (see **Table S3**).

1249 **Two new conserved positions for classes I, II and III CPD PL.** Some promising new information
1250 can be extracted by the comparative analysis. Indeed, despite many studies on these PL classes, we could
1251 identify 2 specific amino acids (F27 and I55) with yet undefined function. When looking at their position
1252 in the structure, these amino acids do not seem to be directly involved neither in DNA nor in FAD binding.
1253 Nevertheless, they are highly specific suggesting their involvement in the CPD repair mechanism.

1254 **Comparison of classes I, II and III CPD PL and NCRY motifs.** By comparing the three CPD
1255 PL motifs/models with the one from NCRY, we essentially remark the absence of the CPD binding site.
1256 In NCRY motifs, four amino acids involved in the interaction of the CPD lesions by photolyase, E4, N71,
1257 M75 and W114, are absent and respectively replaced by R4, F71, A75 and M114 suggesting the absence of
1258 binding affinity for CPD substrate.

1259 **Comparison of classes I, II and III CPD PL and plant PR CRY motifs.** By comparing the three
1260 CPD PL motifs/models with the one from plant PR CRY, we also remark the absence of the CPD binding
1261 sites in plant PR CRY motif. Interestingly, at two specific positions of the CPD binding sites (M75, W114),
1262 two specific amino acids (V74, Y114) are found in the motif of Plant PR CRY which have been involved in
1263 the ATP binding site described up to now as specific for Plant PR CRY (Orth *et al.*, 2017; Brautigam *et al.*,
1264 2004). Moreover, despite very conserved amino acids in class I CPD PL model such as D45, D49 or E54
1265 (involved in the proton transfer to the FAD), the latter ones are present but not fully conserved in class III
1266 CPD PL and are clearly absent in the plant PR CRY model. This observation suggests that these amino
1267 acids might also be involved, directly or indirectly, in the CPD repair function, and that some variability is
1268 not expected to disrupt the function.

1269 All these examples, experimentally validated by the genetic and functional analysis of selected mutations,
1270 illustrate the strength of ProfileView representative models in extracting important amino acids information
1271 from sequences that can be used to design tailored experiments for discovering new functional activities or
1272 novel biological mechanisms involving the FAD binding domain.

1273

SUPPLEMENTARY TABLES

Protein Family	# seqs	seq length	seq identity	seq similarity
Cryptochrome/ Photolyase (CPF)	397	586± 198aa	20.96	30.56
WW domain	349	30 ± 2aa	35.19	50.83
Glycoside hydrolase family 30 (GH30)	1803	524 ± 235aa	23.62	35.03
HAD/ β -PGM/ Phosphatase-like	391	261 ± 101aa	25.47	37.79
B12-binding domain containing	273	549±83	28.33	40.95
Methylthiotransferase	400	463±65	29.58	46.64
SPASM/twitch domain containing	128	366±36	38.02	51.96

Table S1: **Characteristics of the sets of sequences considered for classification.** To be added to the list of features in Figure I: protein family name, lengths of the protein sequences, sequence identity, sequence similarity. Here, sequence length, identity and similarity are given for the entire sequence, not for the domain used to classify the protein sequences. Identities and similarities were computed using the `needle` command of the EMBOSS package (version 6.6.0) and took into account the full-length sequence, not just the domain portion. Note that the variability of sequence length is due to the fact that sequences might be portions of a protein in the family.

Protein Family	Domain(s)	# seqs	domain length	# models in library	time for model construction	time for classification
Cryptochrome/ Photolyase (CPF)	FAD	397	203 ± 26aa	3735	19h50	15min
WW domain	WW	349	30 ± 2aa	3733	8h42	4min
Glycoside hydrolase family 30 (GH30)	Glyco-hydro-30 & Glyco-hydro-30-2	1803	282 ± 85aa	1803	9h40	30min
HAD/ β -PGM/ Phosphatase-like	HAD & HAD_2	391	165 ± 37aa	4075	17h02	3min
B12-binding domain containing	B12-binding & B12-binding_2	273	103±22	3504	18h49	1min
Methylthiotransferase	RadicalSAM	400	159±25	4501	28h53	1min
SPASM/twitch domain containing	SPASM	29	68±7	2663	12h57	1min
	Radical_SAM	128	159±25	4501	28h53	1min

Table S2: **Computational time and other features.** To be added to the list of features in Figure I: protein family name, domain(s) used for classification, number of sequences before filtering, domain length, number of models constructed for ProfileView analysis, time for model construction and time for classification.

CPF functional class	# Experimentally characterized seqs	# Sequences in the ProfileView subtrees		# Experimental positions	# Positions in the ProfileView motif
		TP	FN		
Animal PR CRY	4	4	0	15	13
(6-4) PL	12	11	1	19	16
Transcriptional Regulator (motifs #1 and #2)	18	18	0	16	7
				16	5
Plant PR CRY	8	8	0	47	35
Class I & III CPD PL	15	15	0	33	26
Class II CPD PL	5	5	0	22	18
CRY Pro	2	2	0	11	10
CRY DASH	8	8	0	12	9
Overall	72	71	1		

Table S3: **Validation of ProfileView on functionally characterised CPF sequences and on functionally characterised positions in CPF sequences.** For each representative motif of a CPF functional class, we report the number of CPF sequences with a characterised function, the number of sequences belonging to the associated ProfileView subtree, the number of experimentally characterised positions listed in **Supplemental file** “CPF_mutants_used_for_validation.xlsx” and the number of these positions that belong to the associated motif. For transcriptional regulators, we distinguish the two ProfileView motifs (#1 and #2 in the text) and report the corresponding characterized positions in two different lines of the table. The total number of experimentally characterised sequences to be classified is reported in the line “Overall”. The sequence identified as FN corresponds to the one left white in the ProfileView tree of Fig S1.

Correspondance among groups of WW sequences					Experimental characterisation				Computational classification	
Ingham groups	Russ classes	Otte groups	ProfileView subtrees	Tubiana groups	Ingham	Russ	Otte	Total	ProfileView	Tubiana
A	I	Y	T_1	I	3	18	20	35	35	32(34)
B	II+III+ Im+I/IV	L	T_2	II/ III	3	3	2	5	5	15(16)
		Ra	T_3		1	1	4	4		
		Rb	T_4		2	2	2	3		
		Poly-P	T_5		1	3	2	5		
C	IV	posS/posT	T_6 & T_7	IV	1	1	2	2	2	2(2)
Overall					54				54	49(52)

Table S4: **Validation of ProfileView on 54 functionally characterised sequences of the WW domain family.** ProfileView classification is based on 7 distinct subtrees corresponding to the six Otte’s groups (subtrees T_6 and T_7 are associated to posS/posT-group in Otte), the three Ingham’s groups, and the three Russ’s classes, as indicated. This correspondance is reported in the three outer circles of the ProfileView tree in **Fig. S11**, where the names of the ProfileView subtrees are also indicated. The total number of functionally characterised sequences belonging to classes or groups in the three experimental studies is reported together with the total number of sequences characterised by the three experiments for each group (central columns). Note that some of the sequences have been experimentally characterised by more than one experiment. The right-most columns report ProfileView and Tubiana’s classifications. For Tubiana, 52 sequences among the 54 ones have been considered for classification as reported in parenthesis. Overall, Tubiana wrongly classifies 3 sequences.

CAZy subfamilies	# of CAZy classified seq.	# of ProfileView classified seq.	
		TP	FN
GH30-1	151	151	0
GH30-2	48	48	0
GH30-3	244	243	1
GH30-4	60	60	0
GH30-5	83	83	0
GH30-6	4	4	0
GH30-7	29	29	0
GH30-8	63	63	0
GH30-9	13	13	0
Overall	695	694	1

Table S5: **CAZy classification versus ProfileView classification of the 695 sequences in the GH30 family.** The GH30 sequences are counted as TP whenever they make the ProfileView subtrees for the corresponding CAZy subfamily and FN whenever they wrongly appear in a subtree of another subfamily. See **Fig. S15**.

EC numbers in CAZy functional annotation	# of CAZy characterised seq.	# of ProfileView classified seq.	
		TP	FN
3.2.1.8	10	10	0
3.2.1.8+3.2.1.136	2	2	0
3.2.1.136	2	2	0
3.2.1.75	7	7	0
3.2.1.21+3.2.1.37	1	1	0
3.2.1.*	3	3	0
3.2.1.45	2	2	0
3.2.1.37	2	2	0
3.2.1.31	1	1	0
3.2.1.38	2	2	0
3.2.1.164	2	2	0
Overall	34	34	0

Table S6: **CAZy characterisation based on EC numbers versus ProfileView classification of the 34 sequences in the GH30 family.** The GH30 sequences are counted as TP whenever they belong to the ProfileView subtrees corresponding to the CAZy subfamilies GH30-1,..., GH30-9 (GH30-1: 3.2.1.45 and 3.2.1.21+3.2.1.37; GH30-2: 3.2.1.37; GH30-3: 3.2.1.75; GH30-4: 3.2.1.38; GH30-5: 3.2.1.164; GH30-6:3.2.1.136; GH30-7: 3.2.1.*; GH30-8: 3.2.1.8, 3.2.1.136, 3.2.1.8+3.2.1.136; GH30-9: 3.2.1.31) and FN whenever they wrongly appear in a subtree of another class. We define FN only for classes of more than 3 sequences. See **Fig. S15**.

HAD functional classes	# of SFLD characterised seq.	# of ProfileView classified seq.	
		TP	FN
β -phosphoglucomutase	43	43	0
phosphonoacetaldehyde hydrolase	36	36	0
Phosphoglycolate phosphatase	59	59	0
2-haloacid dehalogenase	113	113	0
2-deoxyglucose-6-phosphatase	6	6	0
glycerol-3-phosphate phosphatase	2	2	0
Overall	259	259	0

Table S7: **SFLD characterisation versus ProfileView classification of the 259 HAD/ β -PGM/Phosphatase-like sequences of the Haloacid Dehydrogenase family.** The sequences are counted as TP whenever they make the ProfileView subtrees for the functional class and FN whenever they wrongly appear in a subtree of another class. We define FN only for classes of more than 3 sequences. The SFLD classes correspond to distinct ProfileView subtrees, hence the FN column contains only 0s. See **Fig. S16**.

B12-binding domain containing functional classes	# of SFLD characterised seq.	# of ProfileView classified seq.	
		TP	FN
anaerobic magnesium-protoporphyrin-IX monomethyl ester cyclase Q bacteriocin maturation	81	80	1
bacteriocin maturation	78	78	0
hopanetetrol cyclitol ether synthase	93	89	4
ladderane biosynthesis	1	1	0
valine cyclopropanase	1	1	0
OxsB-like	1	1	0
paromamine deoxygenase	3	3	0
Overall	258	253	5

Table S8: **SFLD characterisation versus ProfileView classification of the 258 B12-binding domain containing sequences of the Radical SAM family.** The sequences are counted as TP whenever they make the ProfileView subtrees for the functional class and FN whenever they wrongly appear in a subtree of another class. We define FN only for classes of more than 3 sequences. See **Fig. S17**.

Methyltransferase functional classes	# of SFLD characterised seq.	# of ProfileView classified seq.	
		TP	FN
(dimethylallyl)adenosine tRNA methyltransferase (MiaB-like)	99	94	5
ribosomal protein S12 methyltransferase (RimO-like)	98	91	7
threonylcarbamoyl-adenosine tRNA methyltransferase	99	99	0
CDKSRAP1	97	96	1
Overall	393	380	13

Table S9: **SFLD characterisation versus ProfileView classification of the 393 Methyltransferase sequences of the Radical SAM family.** The sequences are counted as TP whenever they make the ProfileView subtrees for the functional class and FN whenever they wrongly appear in a subtree of another class. We define FN only for classes of more than 3 sequences. See **Fig. S18**.

SPASM/twitch domain containing functional classes	# of SFLD characterised seq.	# of ProfileView classified seq.	
		TP	FN
coenzyme PQQ synthesis protein E (PqqE-like)	1	1	0
Kxxx.W cyclic peptide maturase (StrB-like)	14	14	0
adenosyl-hopene transferase	8	8	0
UDP-N-acetyl-tunicamine-uracil synthase (TunB-like)	4	4	0
cytosylglucuronate decarboxylase	0	0	0
neomycin C-like epimerase	1	1	0
pcfB-like	1	1	0
Overall	29	29	0

Table S10: **SFLD characterisation versus ProfileView classification of the 29 SPASM/twitch domain containing subgroup of Radical SAM sequences based on the SPASM domain.** The sequences are counted as TP whenever they make the ProfileView subtrees for the functional class and FN whenever they wrongly appear in a subtree of another class. We define FN only for classes of more than 3 sequences. See **Fig. S19**.

SPASM/twitch domain containing functional classes	# of SFLD characterised seq.	# of ProfileView classified seq.	
		TP	FN
coenzyme PQQ synthesis protein E (PqqE-like)	1	1	0
Kxxx.W cyclic peptide maturase (StrB-like)	14	14	0
adenosyl-hopene transferase	89	88	1
UDP-N-acetyl-tunicamine-uracil synthase (TunB-like)	4	4	0
cytosylglucuronate decarboxylase	2	2	0
neomycin C-like epimerase	4	4	0
pcfB-like	1	1	0
Overall	115	114	1

Table S11: **SFLD characterisation versus ProfileView classification of the 115 SPASM/twitch domain containing subgroup of Radical SAM sequences based on the Radical SAM domain.** The sequences are counted as TP whenever they make the ProfileView subtrees for the functional class and FN whenever they wrongly appear in a subtree of another class. We define FN only for classes of more than 3 sequences. See **Fig. S20**.

Cryptochrome/Photolyase Family

■ (6-4) photolyase	■ Trans. regulators	■ Class I CPD photolyase	■ Plant-like photoreceptor CRY
■ Animal photoreceptor CRY	■ CRY DASH	■ Class III CPD photolyase	■ Plant photoreceptor CRY
■ NCRY	■ CRY Pro	■ Class II CPD photolyase	■ N/A

Function

● Circadian	● 6-4 photolyase	● CPD photolyase	● ssDNA photolyase	● Photoreceptor
● Signaling				

Figure S1: ProfileView tree of 307 FAD-binding domain sequences built from FAD-binding domain (PF03441) models from Pfam v31 using a hierarchical agglomerative clustering strategy. Colors of subtrees are identified by representative models and correspond to known CPF classes, with the exception of the NCRY subtree. External coloured labels define known functions for the sequences. Some of the 307 sequences are known to hold multiple functions and are labelled by two colors. The function “signalling” (grey) refers to signalling processes of different nature (photoreceptor, transcription, unknown). Numbers on the internal nodes correspond to the percentage of sequences in the corresponding subtree that are separated from the remaining sequences in the tree by the best representative model occurring in the model library.

Figure S2: Motif for the NCRY sequences of the CPF family and their structural modelling. **A.** Motif resulting from the representative model of NCRY sequences (see Fig. 3). The positions of this model that are also conserved in the model representative of the class I CPD PL sequences in B are indicated with cyan bullets, below the motif. **B.** Motif resulting from the representative model of classes I & III CPD PL sequences (see Fig. 3). The positions of this model that are also conserved in the model representative of the NCRY sequences in A are indicated with beige bullets, below the motif. **C.** Homology model of the FAD *P^tNCRY* structure where all conserved residues in the NCRY motif (all positions making the motif in A) are highlighted in orange. Compare with the NCRY specific residues highlighted on the same homology model in D. **D.** All conserved residues in the NCRY motif that are NCRY specific (all positions in the motif in A marked with a beige bullet but not with a cyan one) are highlighted in green. Compare with C.

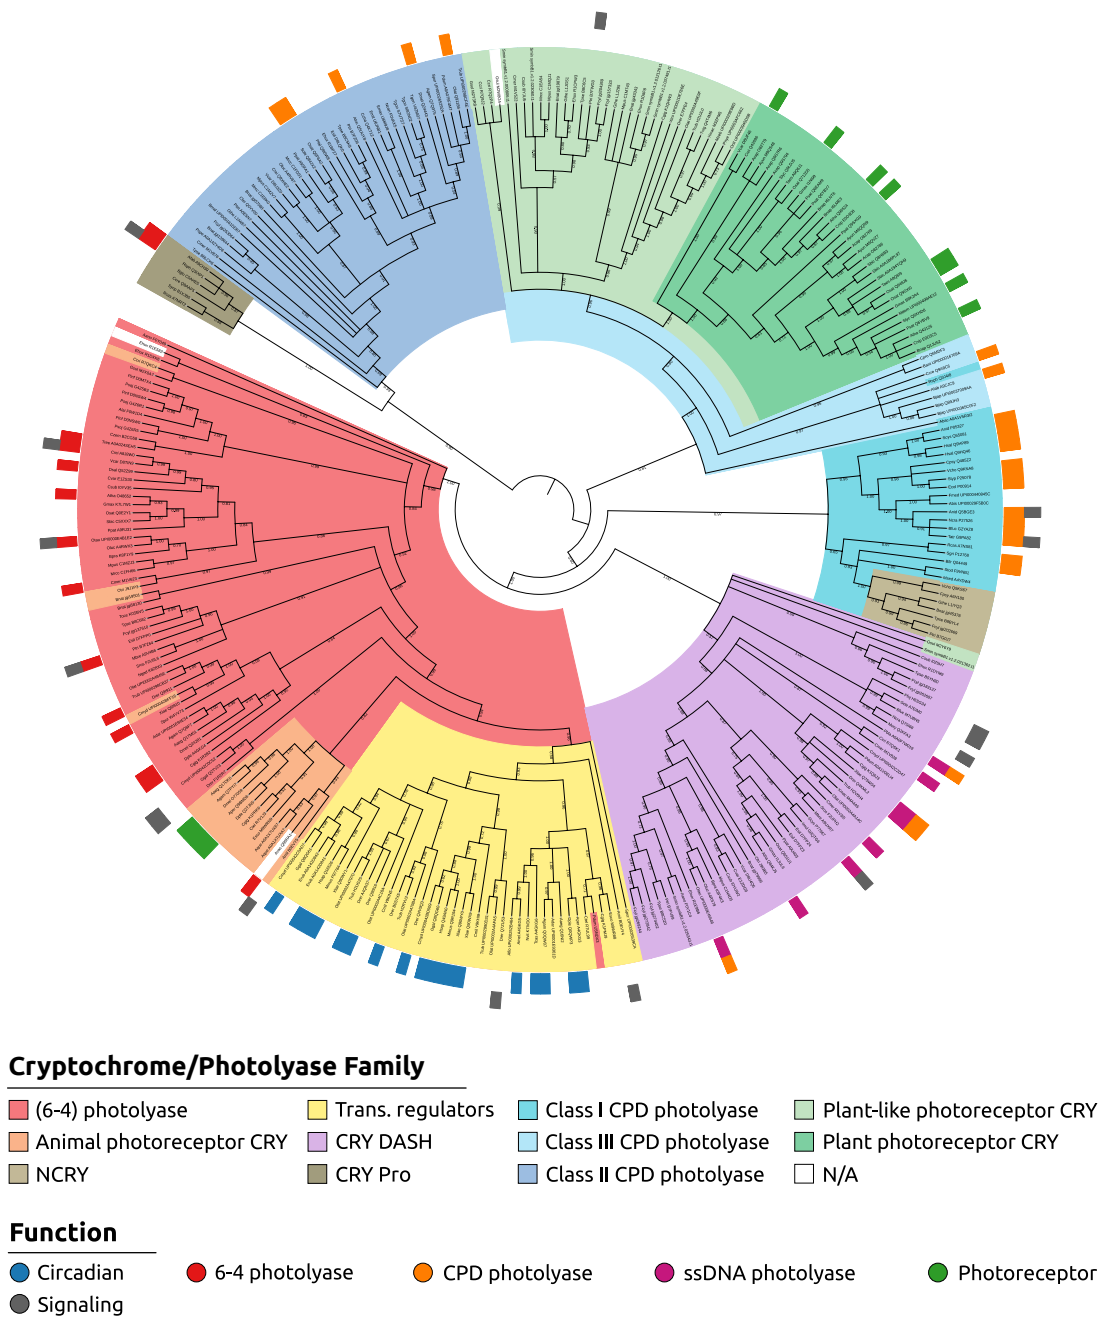

Figure S3: **Phylogenetic tree constructed from 307 CPF sequences.** Each sequence in the phylogenetic tree is coloured as in the ProfileView tree. Colors of internal subtrees are induced by sequence coloring. External labels report known functions for the sequences (see legend of **Fig. S1**). Numbers on the branches are bootstrap values.

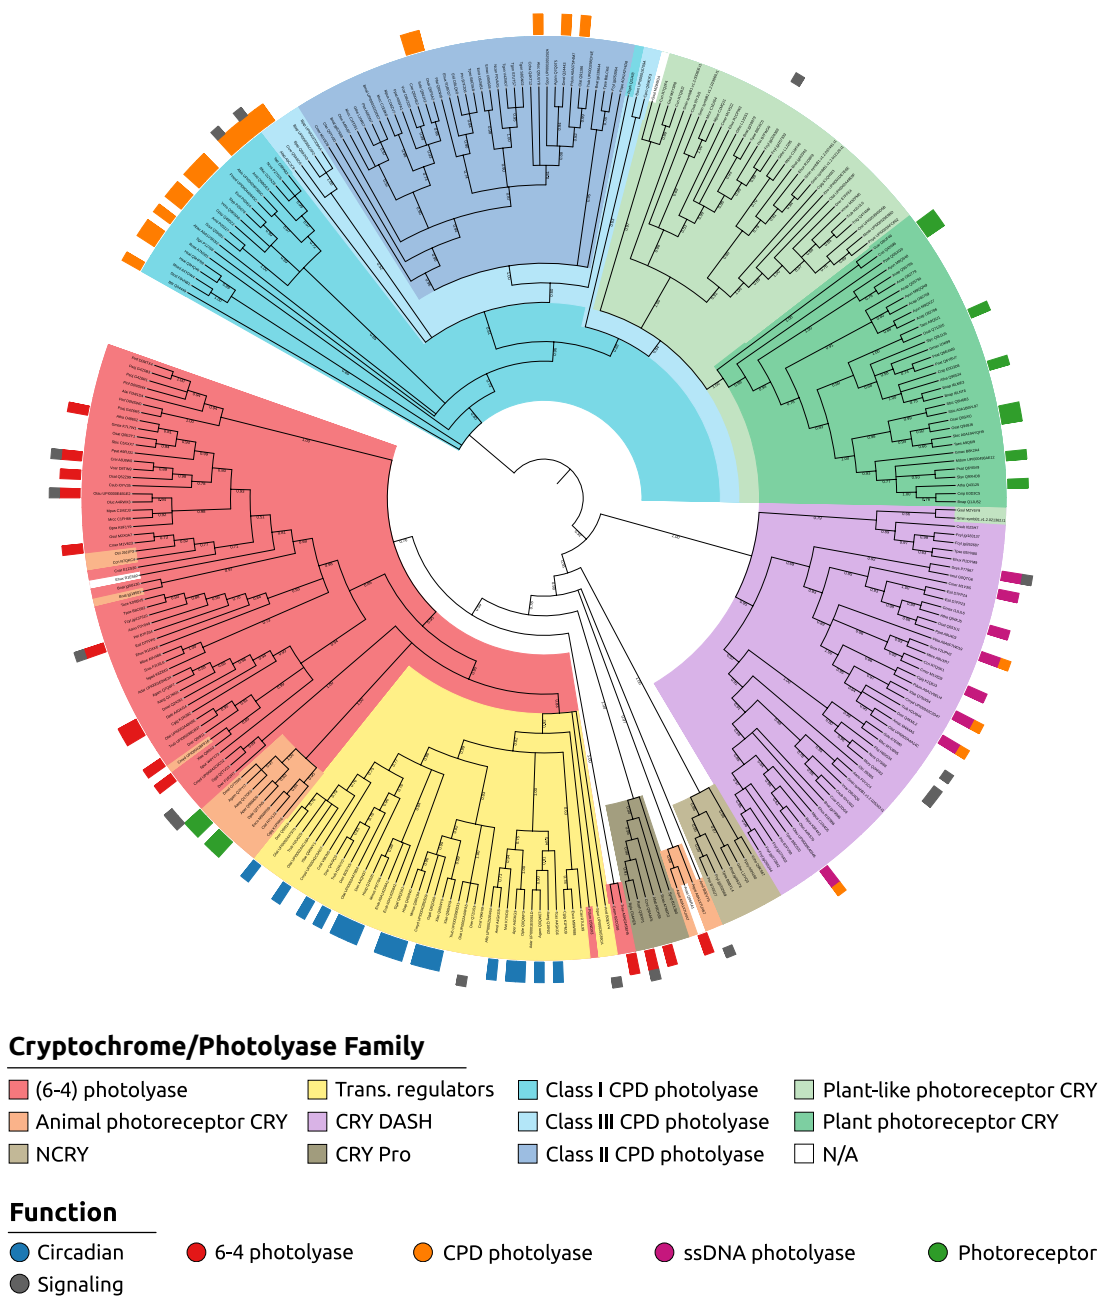

Figure S4: **Phylogenetic tree constructed from 307 FAD-binding domain sequences.** Each sequence in the phylogenetic tree is coloured as in the ProfileView tree. Colors of internal subtrees are induced by sequence coloring. External labels report known functions for the sequences (see legend of **Fig. S1**). Numbers on the branches are bootstrap values.

Figure S5: Eleven motifs for 10 subtrees in the ProfileView tree of CPF. Each motif for a class is represented by the most conserved positions in the corresponding representative model, that is positions showing > 60% frequency in the associated alignment (see Methods). Below each position, the coloured dots indicate that the position is well-conserved in other motifs (after their alignment; see Methods). Circled dots indicate that the position in the motif is not conserved as much in another motif (see Methods). The possible asymmetric distribution of color dots or an absence of dots between comparable positions in motifs is explained in Methods. Specific positions in a motif have no additional dot. The transcriptional regulators' subtree, represented by two distinct representative models, is provided with two independent motifs. For each motif, coloured dots are ordered, from top to bottom, depending on the best E-values given by hhblits to the pairwise alignments.

Figure S6: Eleven motifs for 10 subtrees in the ProfileView tree of CPF (continued). See legend in Fig. S5.

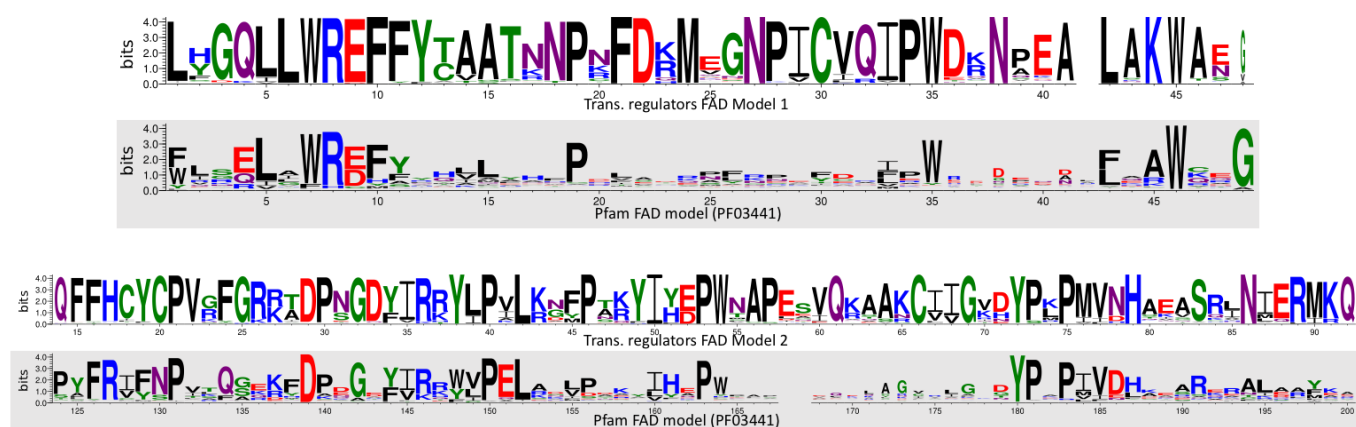

Figure S7: Comparison between trans. regulators models and Pfam models for the CPF family. Alignment of the two full models, corresponding to the trans. regulators motif 1 in A (top) and the trans. regulators model 2 in B (bottom), on two distinct regions of the Pfam FAD model PF03441 (grey background). The regions do not overlap.

Figure S8: Sequence alignment for the pair of CPF sequences U5NDX3 and R7UL99. The alignment has been realised at https://www.ebi.ac.uk/Tools/psa/emboss_needle/. The sequence U5NDX3 has been classified by ProfileView as a “(6-4) PL” and the sequence R7UL99 as a “transcriptional regulator” sequence. In green: positions matched by the conserved motif, associated with the representative model of the “(6-4) PL” subgroup of CPF, and displaying the same amino acid of the motif. In blue: as in green but where the amino acid is different in the motif.

Figure S9: Sequence alignment for the three CPF sequences Q6MDF3, D8UF46 and Q485Z2. The alignment has been realised at <https://www.genome.jp/tools-bin/clustalw>. It displays 67.2% of sequence similarity (43.8% of sequence identity) between Q6MDF3 and D8UF46, and 62.6% of sequence similarity (45.6% of sequence identity) between Q6MDF3 and Q485Z2 which explain the topology of the CPF and FAD phylogenetic trees. Sequence Q6MDF3 is classified as “Class III CPD Photolyase” by ProfileView, D8UF46 as “Plant Photoreceptor CRY” and Q485Z2 as “Class I CPD Photolyase”. Top: 66 positions in the alignment are colored in red/purple because they are positions in the **representative motif for Classes I & III CPD photolyase (Fig. S6)**. In 34 of these positions, the three sequences share the same amino acid and in 16 of them (purple), sequence D8UF46 does not share the amino acid with Q6MDF3 and Q485Z2, suggesting that Q6MDF3 and Q485Z2 are functionally closer sequences than Q6MDF3 and D8UF46, as suggested by the phylogenetic tree of CPF sequences (Fig. S3). Bottom: 83 positions in the alignment are colored in blue/cyan because they are positions in the **representative motif for Plant Photoreceptor CRY (Fig. S5)**. In 43 of these positions, the three sequences share the same amino acid and in 17 of them (cyan), sequence D8UF46 does not share the amino acid with Q6MDF3 and Q485Z2, suggesting that D8UF46 is functionally distinct from Q6MDF3 and Q485Z2.

Figure S10: **Phylogenetic tree for WW domains.** The phylogenetic tree for WW domains shows that sequences classified in the same group by ProfileView appear in different subtrees, often scattered in the tree. The same holds true for those sequences known to represent the same functional class for Ingham, Russ and Otte's classifications.

Figure S11: ProfileView tree for WW domains; compatibility with experimental and computational classification. Larger size of Fig. 5D.

Figure S12: **Representative models in ProfileView tree of WW domains.** Models are representative of the sequences organised in the colored subtrees of **Fig. 5**. For Otte's classes containing more than one representative model, the order, from top to bottom, corresponds to subtrees read anticlockwise in the outer circle (brown scale) of **Fig. 5**, corresponding to Otte *et al* classification.

Figure S13: Ten motifs for 11 subtrees in the ProfileView tree of WW domains, based on *hhblits* conservation criteria. Each motif for a group is represented by the most conserved positions in the corresponding representative model, that is positions showing > 60% frequency for *hhblits* in the associated alignment (see Methods). Notice that by using the *hhblits* criteria, one of the R_a models does not provide any conserved motif (this is due to the very low number of sequences in the alignment generating the model, 20, and to the length of the model). Compare to **Figure S14**.

Figure S14: **Eleven motifs for 11 subtrees in the ProfileView tree of WW domains, based on amino acid counting.** Each motif for a group is represented by the most conserved positions in the corresponding representative model, that is positions showing > 90% amino acid frequency (excluding gaps) in the associated alignment (see Methods). Note that this conservation criteria recovers 4 motifs for the R_a group. Compare to **Figure S13**.

Tree scale: 10

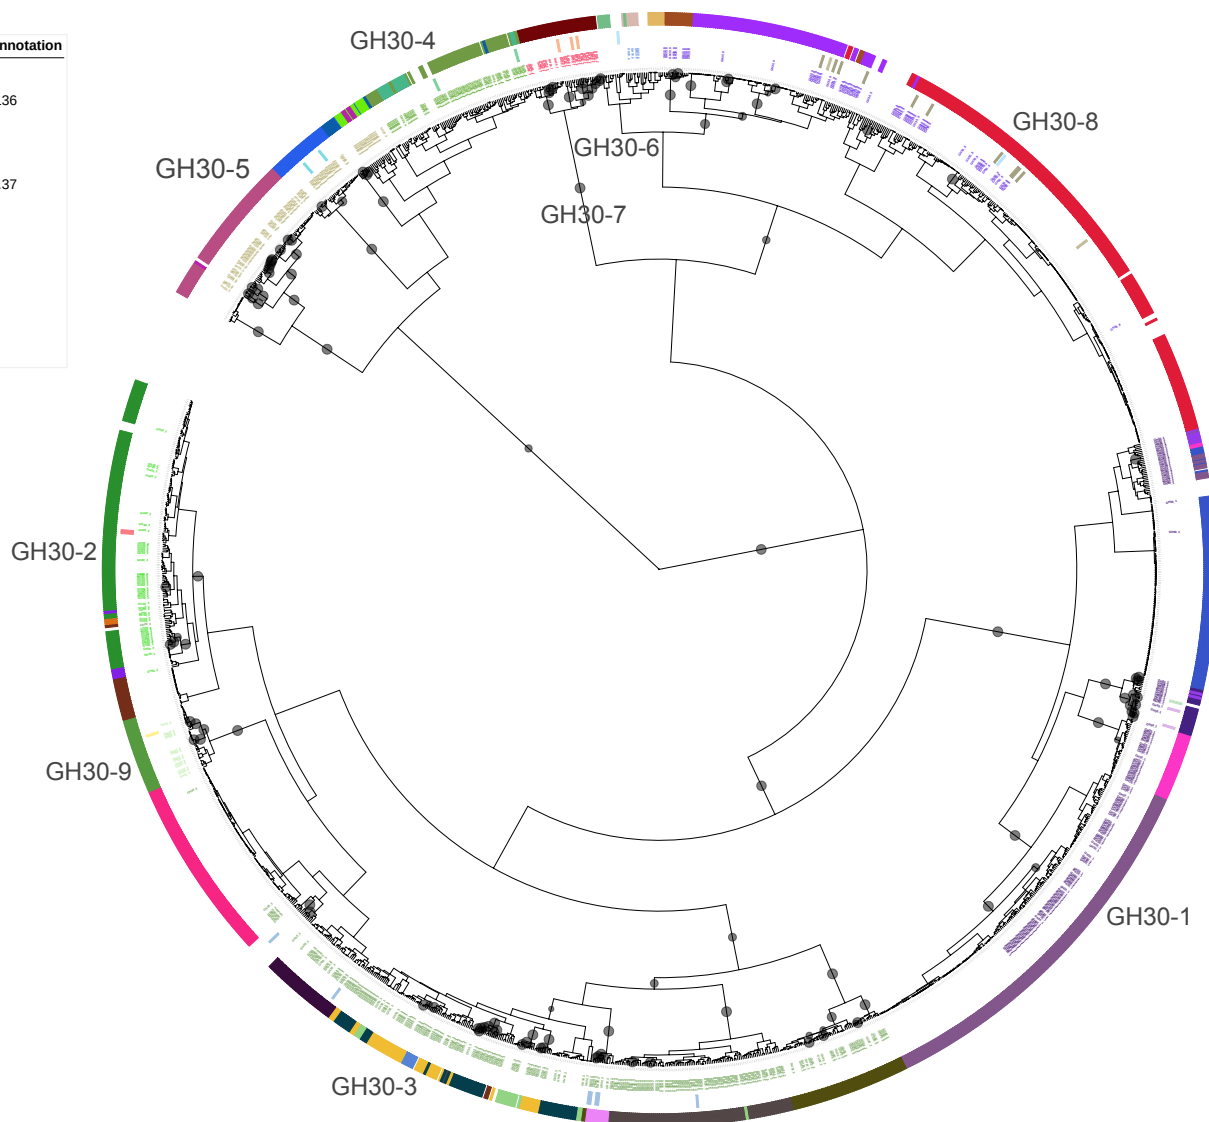

Figure S15: ProfileView tree of GH30 sequences. The tree is based on the construction of models for the two pfam domains PF02055 (Glyco_hydro_30) and PF14587 (Glyco_hydr_30_2). Black dots in the tree indicate the existence of representative models separating at least 75% of the sequences in the subtree (note that lowering the threshold to 50% provides comparable results). The first external ring contains the labels of CAZy subfamilies (GH30_1,..., GH30_9), also indicated in larger characters on the annotated tree for an easier reading. Sequences and their classification correspond to those used in Figure 3 of (Barrett and Lange, 2019). The second ring reports the existence of a "EC number" providing the functional annotation in CAZy. The EC numbers and their associated colours are indicated on the top left (GH30-1: 3.2.1.45 and 3.2.1.21+3.2.1.37; GH30-2: 3.2.1.37; GH30-3: 3.2.1.75; GH30-4: 3.2.1.38; GH30-5: 3.2.1.164; GH30-6: -; GH30-7: 3.2.1.*; GH30-8: 3.2.1.8, 3.2.1.136, 3.2.1.8+3.2.1.136; GH30-9: 3.2.1.31). The third and most external ring reports CUPP clustering (Barrett and Lange, 2019). Different colours are used to indicate different CUPP clusters. See **Table S5**.

HAD, Beta-PGM, Phosphatase Like

- beta-phosphoglucomutase
- phosphonoacetaldehyde hydrolase
- phosphoglycolate phosphatase
- 2-haloacid dehalogenase
- 2-deoxyglucose-6-phosphatase
- glycerol-3-phosphate phosphatase

Figure S16: ProfileView classification tree of the HAD/ β -PGM/Phosphatase-like subgroup of Haloacid Dehydrogenase in SFLD. Validation test of ProfileView performance. See Table S7.

Figure S17: ProfileView classification tree of the B12-binding domain containing subgroup of Radical SAM in SFLD. Validation test of ProfileView performance. See Table S8.

Figure S18: ProfileView classification tree of the Methylthiotransferase subgroup of Radical SAM in SFLD. Validation test of ProfileView performance. See Table S9.

SPASM/twitch domain containing

- coenzyme PQQ synthesis protein E (PqqE-like)
- KxxxW cyclic peptide maturase (StrB-like)
- adenosyl-hopene transferase
- UDP-N-acetyl-tunicamine-uracil synthase (TunB-like)
- cytosylglucuronate decarboxylase
- neomycin C-like epimerase
- pcfB-like

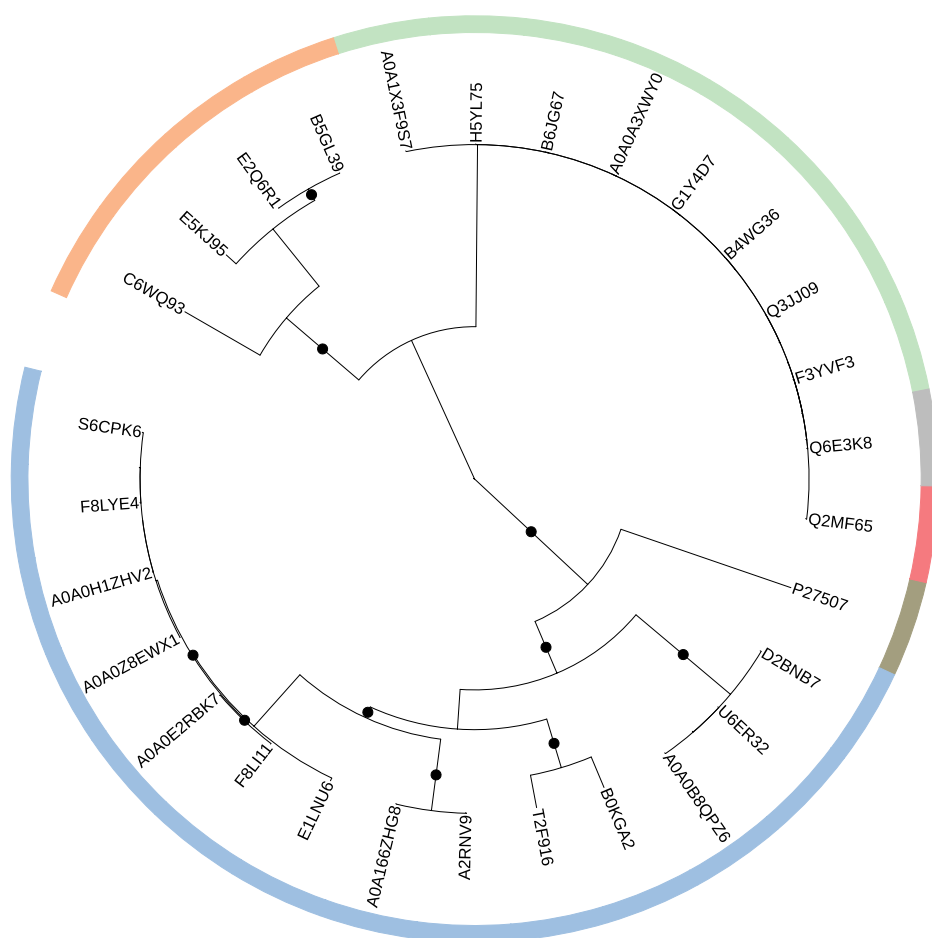

Figure S19: ProfileView classification tree of the SPASM/twitch domain containing subgroup of Radical SAM in SFLD based on the SPASM domain. Validation test of ProfileView performance. See Table S10.

SPASM/twitch domain containing

- coenzyme PQQ synthesis protein E (PqqE-like)
- KxxxW cyclic peptide maturase (StrB-like)
- adenosyl-hopene transferase
- UDP-N-acetyl-tunicamine-uracil synthase (TunB-like)
- cytosylglucuronate decarboxylase
- neomycin C-like epimerase
- pcfB-like

Figure S20: ProfileView classification tree of the SPASM/twitch domain containing of Radical SAM in SFLD based on the Radical SAM domain. Validation test of ProfileView performance. See Table S11.

Figure S21: ProfileView classification tree of CPF sequences and PANTHER classification. The PANTHER classification of CPF sequences is plot on the external ring of the CPF ProfileView classification tree (Fig. S1).

Figure S22: Phylogenetic tree of CPF sequences and PANTHER classification. The PANTHER classification of CPF sequences is plot on the external ring of the CPF phylogenetic tree (Fig. S3).

Figure S23: **Schemas of the CUPP and ProfileView trees on GH30 sequences.** A. Topology of the CUPP tree reported; reproduced from Figure 2 in (Barrett and Lange, 2019). B. Topology of the ProfileView tree. Colors and numbers correspond to GH30 subfamilies.

Tree scale: 10

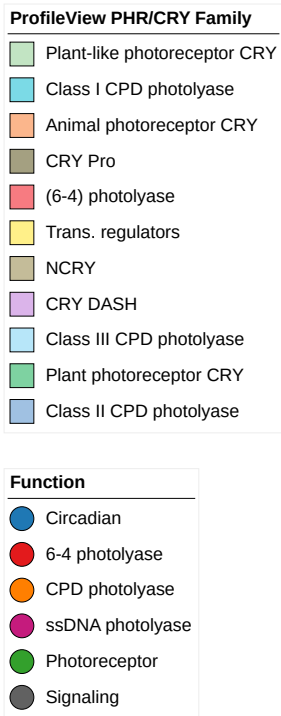

Figure S24: **CUPP tree of CPF sequences, constructed with FAD sequences.** Sequence names in the tree are coloured with ProfileView classification (with the same colour assignment of **Fig. S1**). CUPP clusters are represented by the first layer of colours around the tree (in clockwise order: dark purple, blue, pink, light purple, brown, black, violet, green, fuchsia). The two most external layers correspond to the experimental classification coming from the literature. The same information was used for ProfileView performance analysis. Compare to **Fig. S1**.

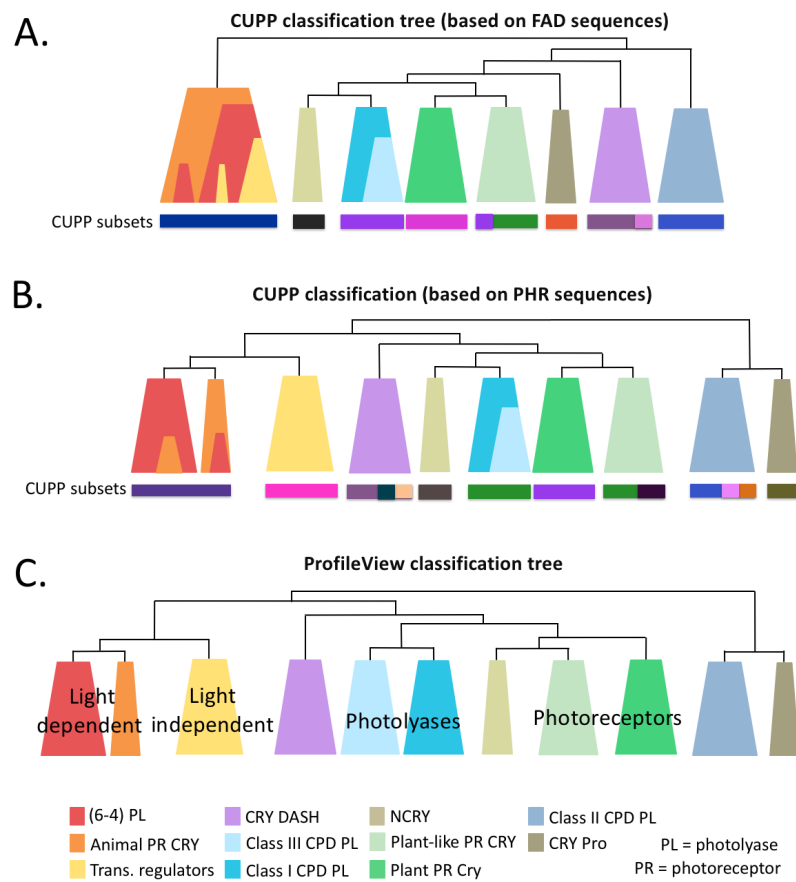

Figure S25: Schemas of the CUPP and ProfileView trees on CPF sequences. A. Topology of the CUPP tree constructed on FAD sequences. B. Topology of the CUPP tree constructed on PHR sequences. C. Topology of the ProfileView tree constructed on FAD sequences; taken from **Fig. 3** for an easy comparison.

Figure S26: CUPP tree of CPF sequences, constructed with PHR sequences. See legend of Figure S24.

Tree scale: 1

Figure S27: CUPP tree of WW domain sequences.

Figure S28: **Sequence filtering and sequence selection in ProfileView pipeline.** A. Phylogenetic tree of CPF input sequences where filtered sequences (that is sequences with no match of the FAD domain) are highlighted in red. Note their long branch length. B. The three types of matches between a model and a sequence used to select sequences in ProfileView. The hit, between a motif and a sequence, might involve the extreme of a sequence (top - overlapping match) or an internal region of the sequence (middle and bottom). For this latter, the motif might match the sequence only partially (middle - partial matching) or fully (bottom - complete matching).

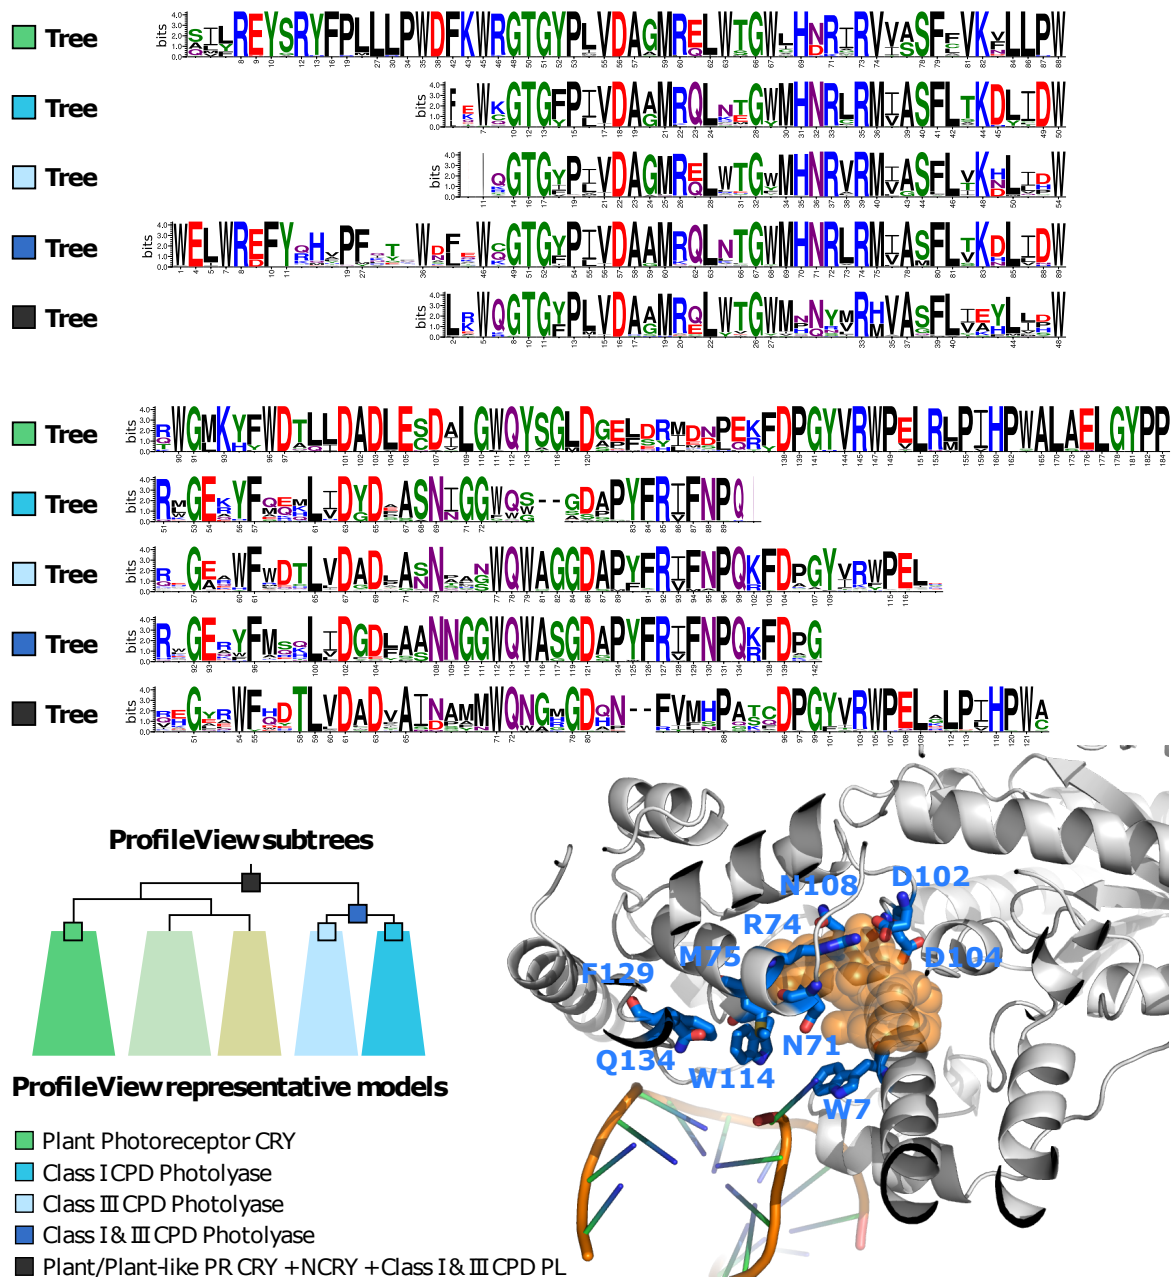

Figure S29: **Five motifs for 5 subtrees in the ProfileView tree of the CPF family.** Five representative models associated with internal nodes in the ProfileView tree are aligned. Numbered positions correspond to conserved positions belonging to the associated representative motif. The absence of the number indicates less conserved positions. The alignment has been constructed using plant PR as a template model and all others as query models. Neither plant-like PR CRY nor NCRY models were considered because no functionally characterised sequences are known for these models. The NCRY motif (associated with the beige subtree on the bottom) was not added because no functional information is available for comparison (see Fig. S2). The length of a motif depends on the length of the associated model, selected as best representing the sequences in a subtree. The PDB structure (1TEZ) highlights residues in interaction with DNA (W7, N71, W114 at < 5Å) and the FAD substrate (W7, N71, R74, M75, D102, D104, N108 at < 5Å). All residues highlighted in the structure have been explained in the text.
