31 **Abstract**

32 Conservation science is a crisis-oriented discipline focused on delivering robust answers to reducing
33 human impacts on nature. To explore how the field might have changed during the past two decades,
34 we analyzed 3,245 applications for oral presentations submitted to the Student Conference on
35 Conservation Science (SCCS) in Cambridge, UK. SCCS has been running every year since 2000, aims
36 for global representation by providing bursaries to early-career conservationists from lower-income
37 countries, and has never had a thematic focus, beyond conservation in the broadest sense. We found
38 that the majority of submissions to SCCS were based on primary biological data collection from local
39 scale field studies in the tropics, contrary to established literature which highlights gaps in tropical
40 research. Our results showed a small increase over time in submissions framed around how nature
41 benefits people as well as a small increase in submissions integrating social science. Our findings also
42 suggest that students and early-career conservationists could provide pathways to increased availability
43 of data from the tropics and for addressing well-known biases in the published literature towards
44 wealthier countries. We hope this research will motivate efforts to support student projects, ensuring
45 data and results are published and made publicly available.

47 Student

48 **1. Introduction**

49 Conservation science focuses on understanding and reducing the negative impacts of human activities
50 on nature, and has, from its inception, been framed as a “mission-oriented discipline” (Soulé 1985). It
51 has its origins in biology and, as a result, its initial emphasis was on describing and explaining the
52 distribution of biodiversity as well as the ecological and evolutionary processes shaping the diversity
53 of life under human pressure. However, over the last few decades it has become increasingly clear that
54 better understanding biological processes alone is insufficient in identifying robust solutions to reduce
55 pressures on nature and the environment (Balmford and Cowling 2006; Bennett et al. 2017; Kareiva
56 and Marvier 2012; Meine et al. 2006). This has led to the integration of the social sciences, economics,
57 and psychology to understand the role of people in addressing conservation problems (Mace 2014;
58 Martin et al. 2012b; Teel et al. 2018) and an interest in the motivations for conserving nature (Greenwald
59 et al. 2013; Kareiva 2014; Kareiva and Marvier 2012; Noss et al. 2013; Soule 2013).

60 Even though primary data are the foundation for conservation science and management (Tewksbury et
61 al. 2014; Wilson 2017), the proportion of published studies based on primary data collection has
62 decreased over the past two decades, though they still represent 70% of ecological studies (Ríos-Saldaña
63 et al. 2018). In addition, the conservation literature continues to exhibit considerable geographical
64 biases toward wealthier, often English-speaking countries (Amano and Sutherland 2013; Martin et al.
65 2012a) and certain taxonomic groups (Clark and May 2002) and away from the tropics (Collen et al.
66 2008; Mammides et al. 2016; Meijaard et al. 2015),. These biases limit our ability to assess what
67 conservation actions work and where.

68 However, analysis of trends in peer-reviewed articles can give an unrepresentative picture of the work
69 being done on the ground (Godet and Devictor 2018). Understanding the extent to which the peer-
70 reviewed literature is missing specific types of studies or research from certain parts of the world can
71 help to highlight publications gaps and improve the uptake of data and experiences outside the published
72 literature sphere. One possible pathway to address the evidence gap and entrenched biases is to analyze
73 conference submissions. While not without possible biases of their own, conference submissions may
74 be less vulnerable to some of the issues in the peer-reviewed literature (e.g. positive-results publication
75 bias, English language skills) and could therefore offer an additional view of what is happening on the
76 ground, thus helping to identify the disconnect between on-the-ground research and the published
77 literature with the aim to utilizing the full potential of the conservation research community.

78 In this study, we assessed the scope, data and methods of studies submitted for presentation at the
79 Student Conference on Conservation Science (SCCS) in Cambridge, UK using a database of >3000
80 applications compiled for this study. To our knowledge, SCCS is the oldest dedicated student
81 conservation conference. Over the 20 years it has been running, it has welcomed applications from
82 bachelor, masters and PhD students. It has never had a thematic focus but instead encourages
83 submissions from across the diverse disciplines of conservation science. It has consistently received

84 applicants from around the world, in part thanks to its provision of bursaries to those from lower income
85 countries. We classified these applications to explore patterns and trends over time in what conservation
86 students study, focusing on potential changes in framing, the types of studies conducted, the methods
87 used, and the integration of data and ideas from the social sciences. We were particularly interested in
88 understanding if the transition from conservation as a predominantly biological science to a more multi-
89 disciplinary one had changed the framing around the value of nature to people or the integration of the
90 social sciences.

91 **2. Material and methods**

92 We included 3,487 submissions for oral presentations at SCCS covering 15 individual years spanning
93 2002-2019. This represented the years for which we had all conference submissions, regardless of
94 whether the applicant had subsequently been invited to present at the conference. Ethics approval was
95 obtained through the Human Biology Research Ethics Committee, School of Biological Sciences,
96 University of Cambridge (ref no.: PRE.2018.068). All submissions were anonymized, and e-mails were
97 sent to all applicants asking them to reply if they did not want to be included in the study. This led to
98 the removal of seven submissions.

99 The data extraction protocol and guidelines were developed prior to reviewing the submissions (Table
100 S1). The protocol was pilot tested on a subset of submissions ($n = 20$) by a sub-group of reviewers and
101 subsequently revised based on these experiences. Two workshops were conducted prior to the data
102 extraction to explain and discuss the final protocol. In total, 25 reviewers participated in the data
103 extraction. The conference-submissions were assigned randomly among all 25 reviewers, with each
104 reviewer extracting data from approximately 140 abstracts. The year of submission was removed to
105 avoid biasing the data extraction.

106 **2.1 Data extraction**

107 For each submission (title and abstract), the reviewers extracted information on the applicant
108 (nationality, country of residence, career stage) as well as on 25 elements pertaining to the research
109 carried out by the student. The abstracts for 2002, 2003, and 2006 consisted of a title and an abstract
110 with no formatting requirements. For subsequent years the abstract was divided into four parts: 1) What
111 conservation problem or question does your talk address?, 2) What were the main research methods
112 you used?, 3) What are your most important results?, and 4) What is the relevance of your results to
113 conservation?. The 25 elements covered research locations (e.g. country, region); study type (i.e. field,
114 laboratory, modelling, remote sensing); and scale of study (e.g. local, national, multi-country) (see
115 Table S1 for the full list and definitions). Where possible, answers were assigned to predefined
116 categories (e.g. realm of study: terrestrial, marine, freshwater, coastal, or multiple). In addition,
117 reviewers used 'not sure' where the abstract did not allow a clear interpretation or 'not applicable'
118 where the particular questions were not relevant.

119 Where one or multiple species were studied, we recorded the broad taxon using 16 categories: algae,
120 lichens, plants, fungi, arthropods, marine invertebrates, other invertebrates, fish, amphibians, reptiles,
121 birds, mammals, other, multiple, not applicable, and not sure.

122 For each conference submission each reviewer assessed whether the study primarily addressed
123 ‘Pressure’, ‘State’, or ‘Response’ following the PSR-framework of the Organisation for Economic Co-
124 operation and Development (1993). For example, a study could examine the effect of protected areas
125 (response) in reducing hunting (pressure) on numbers of lions (state). This was done based on an
126 interpretation of the entire abstract. Where more than one category could apply, we used a hierarchical
127 approach to assign a single category to each submission, where ‘response’ superseded ‘pressure’ which
128 superseded ‘state’ - so the example above would be classed as a response study. The hierarchical
129 approach was used to reflect the conceptual thinking behind the PSR-framework, that conservation is
130 the human response to human pressures affecting the natural state of the world.

131 We extracted information on how far human dimensions were included in the studies through two
132 questions. The first addressed whether the submission mentioned conservation benefiting people and/or
133 the importance of involving people in conservation decisions. It was not necessary for the study to be
134 primarily framed around the value of nature to people, only that the role of, or relevance to, people was
135 articulated. The second addressed whether the primary focus of the study was the value nature provides
136 to people.

137 We assessed whether submissions recorded biological data (e.g. species, habitats, genetics or any other
138 data derived from a biological system) and/or socio-economic data (e.g. livelihood issues,
139 economy/finances, attitudes, human behavior, or human behavior change). Additionally, we recorded
140 if any data was collected by the students themselves as well as if there was any not collected by the
141 student.

142 Finally, we recorded the methods for both biological (e.g. transects, camera-traps, remote sensing,
143 interviews) and socio-economic data collection (e.g. interviews, questionnaires). For biological
144 methods the original 20 categories (Table S1) were reduced to six: 1) field data, 2) genetic data, 3)
145 internet/literature search, 4) audio and camera recordings, 5) remote sensing, and 6) other.

146 Following data extraction, 359 (11.1%) submissions were selected for kappa analysis to test the inter-
147 reviewer variability in data extraction. This was done by randomly selecting 10% of the conference-
148 submissions of each reviewer to be re-reviewed by a different randomly selected reviewer. For the years
149 2002 and 2003 we assessed 20% of each year following the same procedure. Kappa analysis was
150 conducted on all questions individually and on overall agreement. Based on this, questions with a
151 Cohen’s kappa score below 0.6 (weak agreement) were not included in the analysis (McHugh 2012).
152 The average Cohen’s kappa for all included questions was 0.78 (S.E. = 0.07, min = 0.64, max = 0.87,
153 Table S2). Only the identification of main threat (Cohen’s kappa = 0.21) did not meet this criterion.

154 The years 2002 and 2003 were assessed separately leading to the exclusion of the Pressure-State-
155 Response questions for those years (Cohen's $\kappa = 0.40$).

156 2.2 Analysis

157 Prior to calculations of proportions, all empty fields, 'not applicable', and 'not sure' were removed.
158 Thus, the number of responses for each year varies across analyses. For questions where we assessed
159 proportional changes over time, we used beta-regression, suitable for proportions, to model the
160 proportion as the dependent variable and year as a continuous independent variable. All analyses were
161 carried out in R 3.5.1 (R Development Core Team 2019).

162 3. Results

163 3.1 Geographical and taxonomic focus

164 We assessed 3,245 submissions after removing 235 that had been submitted but did not contain an
165 abstract and/or title. Over the 18-year period, the conference received applications from 128 countries;
166 the majority of applicants were from India ($n = 454$), United Kingdom ($n = 312$), Kenya ($n = 125$),
167 Nigeria ($n = 121$), or Nepal ($n = 100$). By region, Asia was the largest source of applicants ($n = 992$),
168 followed by Africa ($n = 961$), Europe ($n = 598$) and Latin America ($n = 213$) (Table 1).

169 **Table 1.** Proportion of abstracts across the six regions

Region	Nationality	Residence	Fieldwork	% studies based on own fieldwork	% people focused
Africa	961 (34%)	958 (33%)	1,016 (41%)	82%	36%
Asia	992 (33%)	921 (34%)	949 (39%)	83%	26%
Europe	598 (21%)	846 (21%)	216 (9%)	73%	27%
Latin America	213 (7%)	166 (7%)	222 (9%)	70%	32%
North America	86 (3%)	115 (3%)	16 (<1%)	66%	49%
Oceania	41 (1%)	55 (1%)	38 (2%)	51%	17%

170 Nationality, residence and fieldwork shows the percentage of submissions (after removing those that noted not
171 applicable and not sure) from each region. % fieldwork and % people-focused shows the percentage of
172 submissions, within each region that included fieldwork and a focus on people related values respectively. For the
173 last two columns, submissions were assigned a region based on the nationality of the applicant. Because of
174 different degrees of missing data in individual questions, the sums across columns are not the same.

175 Noticeably there were very few submissions from North America ($n = 86$) and Oceania ($n = 41$). No
176 changes were observed over time in the proportion of applicants from different regions (Fig. S1) and
177 only few, and minor, at the country level (Fig. S2). In terms of country where the study took place, India
178 featured the most ($n = 435$), followed by South Africa ($n = 114$), Kenya ($n = 110$), Nepal ($n = 101$), and
179 Madagascar ($n = 97$). Many applicants from Europe and North America worked outside their own
180 region, which was much less the case with students from other regions (Fig. 1). The vast majority of
181 studies were terrestrial ($n = 2,393$) followed by freshwater ($n = 225$), marine ($n = 177$), multiple ($n =$
182 119) and coastal ($n = 102$). Across taxonomic groups, mammals were the most studied ($n = 875$),
183 followed by plants ($n = 470$), birds ($n = 432$), fish ($n = 121$) and arthropods ($n = 89$), while potentially-
184 important indicator groups, such as amphibians ($n = 58$), fungi ($n = 10$), and lichens ($n = 2$), were far
185 less represented (Fig. 2).

186
187 **Figure 1.** Diagram showing the number of SCCS applicants conducting fieldwork in different regions (the outer
188 ring). The color of the inner (thicker) ring indicates the nationality, grouped by region, of the person conducting
189 the research. The figure shows that there are more Europeans working in Africa, Asia, and Latin America and the
190 Caribbean than there are people from those regions working in Europe.

191 **3.2 Framing**

192 On average, 38% ($n = 1,003$) of studies focused on the state of nature, investigating patterns of
193 biodiversity and processes, followed by 36% ($n = 954$) addressing pressure to biodiversity, and 26% (n
194 $= 671$) addressing responses. No changes were observed between 2007 and 2019 in the proportions of
195 state, pressure and response studies (Fig. 3a).

196 Of all the submissions, 31.3% ($n = 983$) mentioned the importance of conservation benefiting people
197 and/or the importance of involving people in conservation decisions, with no change observed over
198 time. While remaining relatively low, in absolute terms (mean = 11.8%) the number of submissions
199 with a primary focus on the value of nature to people increased significantly (z -value = 2.62, $p = 0.009$,
200 $DF = 13$) almost doubling from 2002 (estimate = 7.0%) to 2019 (estimate = 16.5%; Fig. 3b).

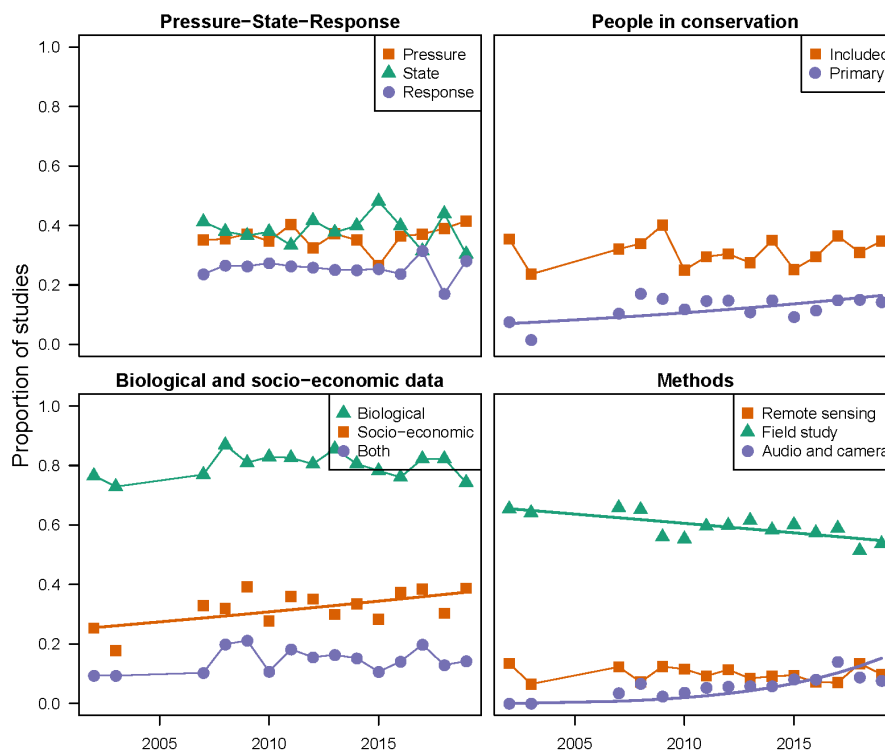

Figure 2. Taxonomic coverage across 2,489 conference submissions (excluding submissions with an ambiguous or no study taxon). Reviewers were explicitly asked to select the main species or higher taxonomic unit of interest. Where other species were described but were not the focus of the study, they have not been recorded.

201 3.3 Data and methods

202 Most submissions (80%, $n = 2,442$) contained biological data, while data on socio-economic aspects
 203 were less common (33%, $n = 998$). Only 15% ($n = 454$) contained both biological and socio-economic
 204 data. For biological data and the combination of biological and socio-economic data, the proportions
 205 showed no change over time. However, the proportion of submissions including socio-economic data
 206 increased over time (estimate = 0.03, S.E = 0.01, $p = 0.004$, DF = 13; Fig. 3c).

207

208 **Figure 3.** Change over time in the proportions of (a) studies that looked at pressure-state-responses, (b) studies
 209 that mentioned the importance of conservation to benefiting people and/or the importance of involving people in
 210 conservation decisions, or studies whose primary focus was to understand the values that nature provides to
 211 people, (c) studies that including biological data or socio-economic data, or both, and (d) studies using different
 212 methods. Studies that noted 'Not applicable', 'Not sure' or did not provide an answer for the questions involved
 213 were not included. Dots are connected where not significant relationship ($p \geq 0.05$) was identified while a
 214 regression line represents that a significant relationship ($p < 0.05$) was identified

215 Most of the data, both biological (66%, $n = 2,001$) and socio-economic 75% ($n = 852$), were collected
216 by the students themselves. Eighty percent ($n = 2,457$) of the submissions contained a field-collection
217 element (Table 1) with 74% ($n = 2,090$) of the submissions covering local-scale studies that looked at
218 one or a few sites, and only 17% ($n = 475$) of studies investigating patterns at national level, 7% ($n =$
219 186) looking at multiple countries, and 2% ($n = 66$) conducting global analyses.

220 The methods used to collect biological data remained relatively constant over time and were dominated
221 by field-based approaches, such as transects, plots and trapping (58.4%, $n = 1,691$). A decrease (from
222 65.5% in 2002 to 54.8% in 2019) was observed in the use of traditional field-based methods (estimate
223 = -0.026, S.E = 0.006, $p < 0.001$, DF = 13), and there was an increase (from 0% in 2002 to 15.2% in
224 2019) in the use of audio and camera recordings (estimate = 0.21, S.E = 0.041, $p < 0.001$, DF = 13),
225 suggesting a change in approach toward more automated methods, rather than a change away from
226 field-based data-collection (Fig. 3d).

227 **4. Discussion**

228 Our results show that the majority of submissions to SCCS were based on primary data collection of
229 biological data from local-scale field studies. These findings suggest a different trend to the concerns
230 raised in previous papers: that there is a decrease in the proportion of field-based studies in the peer-
231 reviewed literature (Carmel et al. 2013; Ríos-Saldaña et al. 2018). Likewise, contrary to the
232 preponderance of researchers from wealthier countries found by reviews of published papers (Amano
233 and Sutherland 2013; Mammides et al. 2016; Martin et al. 2012a), the majority of submissions to SCCS
234 were from Asian and African nationals. These two continents were even more prominent when looking
235 at the countries in which people collected data (Fig 1). For example, citizens from the UK represented
236 the second largest group of applicants, but the UK ranked 15th as a location for fieldwork. The
237 discrepancy, in terms of type and location of studies, between the published literature and submissions
238 to SCCS, highlights a potential barrier in the pathway from fieldwork to publication that warrants
239 further exploration. Furthermore, it suggests that the identified knowledge and data gaps for the tropics,
240 in the published literature (Collen et al. 2008; Mammides et al. 2016; Meijaard et al. 2015), may not
241 only be driven by the lack of research effort and data-collection but also by publication bias. This is of
242 particular concern given many areas in the tropics are of significant biodiversity importance (Brooks et
243 al. 2006; Myers et al. 2000).

244 There is a need to improve the uptake of studies from the tropics in the peer-reviewed literature to
245 ensure the availability of knowledge and data in conservation research and efforts. This will not only
246 directly benefit the conservation community but will also help ensure a greater diversity in the people
247 and views represented within conservation science. To achieve such improvements, it will be important
248 to support the data-collection-publication pipeline in areas currently underrepresented in the published
249 literature. This may include reduced or waived publication fees (already applied by some journals), as
250 well as language support for non-native English speakers, which is a major barrier in the publication

251 process (Amano et al. 2016). There might also a need for capacity building (Legg and Nagy 2006) and
252 to assist people in scientific writing. For example, in a capacity-building program in Africa run by the
253 Tropical Biological Association, a focus on how to write scientific articles resulted in 87 publications
254 (*Pers obs.* R. Trevelyan). Additionally, while the peer-review process is foundational for the publication
255 of scientific studies, it is not the only way to publish data. An increasing number of preprint services
256 and online data repositories allow for data sharing outside the traditional publication pathway. Similar
257 to the role of GenBank (NCBI Resource Coordinators 2017) in molecular biology, such databases might
258 help to publicize data currently unavailable in the public sphere. However, to be successful, this should
259 be linked to transparent standards (Poisot et al. 2019), formalized method of citing the data-collectors,
260 and must be accompanied by the development of appropriate and fair crediting mechanisms for data
261 collectors by institutions and funding bodies. Additionally, data can represent value, both monetary and
262 cultural, thus where fieldwork is taking place outside the country of the institution the access to data
263 should be accompanied by benefit-sharing (Baker et al. 2019).

264 Over the 18-year span of the conferences for which we had data, the number of submissions that
265 focused on the value that nature provides to people increased. This corresponds with the emergence
266 within the conservation community of a ‘nature for people’ framing (Mace 2014), which has profoundly
267 influenced the strategies of some of the world’s largest conservation organizations (e.g. Conservation
268 International and The Nature Conservancy; Kareiva et al. 2014). However, this narrative has been
269 criticized as western-dominated (Tallis and Lubchenco 2014) and as describing a polarization not
270 actually found in the conservation community (Sandbrook et al. 2019). In this light, it is interesting that
271 while we observed a significant trend over time, the proportion of SCCS submissions focused on the
272 services and goods that nature provides to people remained low. Thus, our results suggest that while
273 the emphasis on people is a component in conservation, it is by no means dominant. It is possible that
274 our sample, with a majority from lower-income countries, might be less influenced by this trend in
275 conservation than in higher-income regions. North America and Australia which are among the largest
276 contributors to peer-reviewed journal articles in conservation science are for example almost entirely
277 absent in our sample while also among the strongest proponents of a more people focused conservation
278 narrative (Tallis and Lubchenco 2014).

279 The applications we assessed support suggestions that conservation science is broadening (Teel et al.
280 2018) by revealing an increase over time in the use socio-economic data. However, the proportion
281 remained relatively low across the 18 years. Additionally, the number of studies integrating both
282 biological and socio-economic data did not increase, with only around 16% of studies combining
283 biological and socio-economic data in the same study. This suggests that while conservation has become
284 increasingly multi-disciplinary, there is still considerable scope for further integration (also see
285 Guerrero et al. 2018). The call for integrating socio-economic perspectives into conservation research
286 is not new (e.g. Adams and McShane 1992), and it is increasingly recognized that both biological and

287 socio-economic perspectives are vital to conservation success (Martin et al. 2016). The continued
288 paucity of socio-economic considerations in conservation science we observed highlights the need to
289 broaden the training of future conservation researchers. This requires university departments and
290 faculties to foster integration and to break down silos between disciplines and departments.

291 The majority of studies focused on describing biological states or human pressures while only 26%
292 evaluated conservation interventions and solutions. Our results therefore mirror several papers that
293 highlight the lack of studies assessing the impact of conservation responses (Geldmann et al. 2013;
294 Schleicher 2018). While we recognize that an understanding and description of the state of nature and
295 the pressures it faces provides a foundation for developing effective responses, the under-representation
296 of studies assessing the impact of conservation efforts is concerning, given longstanding calls for
297 increasing evidence on the effectiveness of conservation interventions (Pullin and Knight 2001;
298 Sutherland et al. 2004). Assessing the impact of conservation responses is fundamental to improving
299 their effectiveness (Balakrishna 1999; Ferraro 2009) as well as measuring progress towards achieving
300 policy targets (Fisher et al. 2014). It is possible that the complexity of assessing conservation impact
301 (Baylis et al. 2016) is limiting the number of such studies undertaken by students, who are often
302 constrained by time and may lack the experience required to undertake complex impact assessments.
303 However, it is vital that conservation science increasingly addresses this knowledge gap (Baylis et al.
304 2016; Miteva et al. 2012; Schleicher 2018) to better understand what works, when and why.

305 By following 18 years of submissions from the oldest student conservation conference, our study
306 provides a unique temporal insight into the work undertaken by successive cohorts and early-career
307 conservation scientists. In including all submissions to give a talk, our sample is not biased by the
308 quality of submissions or by temporal shifts in the preferences of the selection committees but represents
309 the full diversity of students applying for SCCS. Nevertheless, our sample might not represent the wider
310 community as self-selection might exclude some from submitting. As with published studies (Amano
311 et al. 2016; Amano and Sutherland 2013), countries (often former British colonies) where it is more
312 common to communicate in English were disproportionately represented and so the conference
313 doubtless does not fully capture a representative sample of all conservation studies. Moreover, the low
314 proportion of marine studies indicates that SCCS has tended to attract a lower proportion of those
315 working on marine conservation, perhaps due to the organizers having mostly terrestrial experience and
316 networks. Likewise, the dominance of field studies from the tropics in the conference submissions might
317 not reflect a dominance of field studies in general. Rather, it is possible that fieldwork in temperate
318 zones is framed more as ecological research without a conservation focus. Nevertheless, our study
319 suggests that there is an untapped resource in field studies and perhaps more tropical research being
320 undertaken by students from tropical countries than is suggested by the published literature.

321 5. Conclusion

322 Based on our findings we see an urgent need to make data generated by tropical fieldworkers more
323 widely available, and for increased efforts in examining the impact of conservation interventions. Any
324 approach should ensure the quality of the data as well as equitable access that respects, acknowledges,
325 and includes the data providers. Our results also highlight the need for further integration of disciplines
326 outside biology. Only through combining understanding of both the natural world and human behaviour
327 can we successfully tackle the great challenges facing Earth's biodiversity, without jeopardizing the
328 sustainable livelihood of our own species.
