Abstract

30

Haploinsufficiency of transcriptional regulators causes human congenital heart disease

32   (CHD) [1]. This observation predicts gene regulatory network (GRN) imbalances [2], but the nature

of dosage-vulnerable GRNs and their contribution to human cardiogenesis and CHDs are

34   unknown. Here, we define transcriptional consequences of reduced dosage of the CHD

transcription factor TBX5 during human cardiac differentiation from induced pluripotent stem

36   (iPS) cells. Single cell RNAseq revealed that transcriptional responses to reduced TBX5 levels

are not homogeneous, and instead, discrete sub-populations of cardiomyocytes exhibit

38   dysregulation of distinct TBX5 dose-sensitive genes related to cellular phenotypes and CHD-

associated genetics. Cellular trajectory inference revealed TBX5 dosage-dependent

40   differentiation paths, with implications for cardiac developmental identity. GRN analysis of the

single cell RNAseq data identified vulnerable nodes enriched for CHD genes, implicating a

42   critical sensitivity to TBX5 dosage in cardiac network stability. A novel GRN-predicted genetic

interaction between *TBX5* and *MEF2C* was validated in mouse, revealing a highly dosage-

44   sensitive pathway for CHD. Our results reveal unforeseen complexity and exquisite sensitivity to

TBX5 dosage in discrete sub-populations of iPSC-derived cardiomyocytes, providing

46   mechanistic insights into human CHDs and quantitative transcriptional regulation in disease.

Introduction

48

CHDs are a leading cause of childhood morbidity and mortality, and incidence of CHD is

50   estimated to be ten-fold higher in human fetuses than live births [3,4]. Many human mutations

2

52 linked to CHD predict reduction in dosage of transcriptional regulators, including transcription factors (TFs) and chromatin-modifying genes [1]. Despite advances in tracing the roles of

54 individual factors, how altered dosage of transcriptional regulators translates to altered transcriptional activity is not known, nor is it known how these altered GRNs disrupt heart development, resulting in CHD.

56 Heterozygous mutations in the T-box TF gene *TBX5* cause Holt-Oram syndrome (HOS) [5,6], which presents with upper limb defects, CHDs, diastolic dysfunction, or arrhythmias. In

58 humans, homozygous *TBX5* loss of function is presumed to cause fetal demise. Altered expression of select genes in mice *in vivo* demonstrate a stepwise sensitivity to reductions in

60 *Tbx5* dosage [7,8]. These findings suggest that a reduction in TBX5 dosage perturbs downstream gene expression, but the overall disrupted networks and mechanisms are not understood.

62 Mechanistic investigation of human CHD has been hampered by a lack of relevant and tractable models. Human heart tissue is largely inaccessible for molecular analysis, and

64 pathological or surgical specimens are limited. However, induced pluripotent stem (iPS) cells, genome editing, directed differentiation, and single cell RNAseq together provide a human

66 cellular platform for gene-centered cardiac disease modeling at single cell resolution. In considering how transcriptional regulator haploinsufficiency might cause CHD, at least two

68 scenarios are possible: 1. That reduced dosage affects genes only in specific anatomical locations, such as the atrial septum. 2. That reduced dosage affects cardiac gene expression

70 broadly, but altered programs manifest as morphologic defects only in structures most sensitive to the disturbance. The first scenario would make it challenging to discover altered gene

72 expression in 2-dimensional cultures if susceptible cell types are absent. The second may predict that homogeneous changes in gene expression might be detected in that context, as

74 corroborated by bulk RNAseq studies of heterozygous human iPS cell models of CHD [9-11]. However, it is likely that relevant, discrete alterations in a complex cell mixture were not

76   detected in those studies. Therefore, how reduced dosage of a transcriptional regulator alters

GRNs in susceptible cells leading to CHD remains unclear.

78

Impaired human cardiac differentiation and function by reduced TBX5 dosage

80   To determine a role for TBX5 dosage in human cardiac biology, we created an allelic

series of human iPS cells mutant for *TBX5* by using CRISPR/Cas9-mediated genome editing, to

82   target exon 3 of *TBX5* at the start of the essential T-box domain (Fig. 1a). We isolated targeted

iPS cell lines: control (*TBX5*[+/+]), heterozygous (*TBX5*[in/+]) and homozygous (*TBX5*[in/del] and

84   *TBX5*[PuR/PuR]) mutants (Fig. 1b, Extended Data 1). TBX5 protein levels in cardiomyocytes

differentiated from these lines were diminished in *TBX5*[in/+] and absent in *TBX5*[in/del] and

86   *TBX5*[PuR/PuR] cells (Fig. 1c), consistent with a dosage-step allelic series of mutant *TBX5* loss-of-

function cell lines.

88   We observed reduced cardiomyocyte differentiation efficiency, a delay in onset of

beating, and worsening sarcomere disarray, by graded loss of *TBX5* (Fig. 1d-j, Extended Data

90   2). Patch clamp analysis revealed lengthened action potentials (AP) in *TBX5*[in/del] cells (Fig. 1k, l;

APD90, adj p-value<0.04 by Holm-Sidak test[12]), consistent with previous findings [13-15]. Fluo-4

92   imaging measurements uncovered protracted calcium transient duration in *TBX5*[in/del] and

TBX5[PuR/PuR] cells (T90 down, adj p-value<9E-4 by Holm-Sidak test), with an intermediate defect

94   in *TBX5*[in/+] cells (adj p-value<0.01) (Fig. 1m, n), consistent with findings in murine postnatal

atrial CMs [16]. These findings may underlie diastolic dysfunction in HOS in mice and humans [17].

96

Resolving TBX5 dosage-sensitive transcriptomes during human cardiac differentiation

98   To determine if reduced TBX5 dosage alters gene expression in potentially vulnerable

cell types, we used a droplet-based single cell RNAseq method with cells collected from

4

100   parental WTC11, control $TBX5^{+/+}$, and mutant $TBX5$ ($TBX5^{in/+}$, $TBX5^{in/del}$) genotypes during

directed cardiac differentiation (Fig. 2a). Heterogeneous cell populations composed of cardiac

102   precursors (CP) at day (d) 6, and cardiomyocytes (CMs) at d11 or d23, were harvested. We

interrogated 64,396 cells with an average normalized read depth of 88,234 reads per cell (Fig.

104   2b-d; Extended Data 3). At d6, we identified 11 cell clusters, representing at least four cell

types, including $POU5F1^+$ pluripotent cells, $MESP1^+$ mesoderm, $ISL1^+$ cardiac precursors and

106   nascent $TNNT2^+$ cardiomyocytes (Extended Data 3). At d11 and d23, differentiated cell types

were identified by specific marker genes (Extended Data 3). This included a diversity of $TBX5^+$

108   cell types, comprising very few $PLVAP^+$ endothelial cells or TTR^+ endodermal cells, some

$COL1A1^+$ fibroblasts and, most abundantly, $TNNT2^+$ cardiomyocytes (Extended Data 3, 4). All of

110   these major cell types were present and detected in each $TBX5$ genotype at d11 or d23

(Extended Data 3).

112   We applied this classification of human cell types to learn more about the genes that

contribute to CHDs. We examined the expression of 376 CHD-associated candidate genes,

114   compiled from [18-25], across the major cell types regardless of $TBX5$ genotypes at d23 (Extended

Data 4, Supplemental Table 1). For many CHD-associated genes, we observed enrichment of

116   gene expression in CMs (e.g.$TBX5, FOXH1, ARID1A, EP300, KDM6A, PKD1$; adj p-value<0.05

by Wilcoxon Rank Sum test), fibroblasts (e.g. $SMARCA2, PITX2, ZEB2, HAND2$; adj p-

118   value<0.05), endoderm (e.g. $TBX3, WDR5, SALL4, NODAL$; adj p-value<0.05), endothelial cells

(e.g. $FGFR1, TGFBR2, SHANK3, KCNJ2$; adj p-value<0.05) or other cell types (Extended Data

120   4). This gene expression dataset provides a resource that helps identify progenitors to these cell

types and may allow further categorization of human CHD-associated candidate genes.

122

TBX5 dose-dependent cellular trajectories during human cardiac differentiation

124   To assess if altered transcriptional states in *TBX5* mutant cells reflected changes in paths of differentiation, we inferred cellular trajectories of each *TBX5* genotype in our allelic

126   series using the R package URD [26], which predicts cellular chronology based on user-determined origins and ends. We defined *POU5F1*[+] cells from d6 as a root and each d23 cluster

128   as an individual tip in a pseudotime tree (Fig. 2b-d, Extended Data 5). *TBX5*[in/+] cells followed a path similar to wildtype and control (collectively "WT) cells during differentiation to CMs (Fig. 2e,

130   f, dashed lines), but within the shared branch, a tip occupied by *TBX5*[in/+] CMs (red arrowhead) was disparate from wildtype (black arrowhead) and control, demonstrating *TBX5*[in/+] CMs distinct

132   from WT. In contrast, *TBX5*[in/del] cells deviated from the differentiation path (Fig. 2g, blue dashed line, blue arrowheads). We identified several genes (e.g. *NAV1, TECRL, LAMA4,* and *NPPA*),

134   which were positively correlated with pseudotime (rho≥|0.4|, p-value<0.05 by two-sided *t* test) in the WT/*TBX5*[in/+] branch, but not in the *TBX5*[in/del] branch (Z-score≥15 by difference in rho),

136   suggesting that these genes were not activated properly in *TBX5*[in/del] cells (Fig. 2h, i, Extended Data 5). Likewise, we identified several genes (e.g. *DES, TBX2, RSPO3,* and *LBH*) that

138   positively correlated with pseudotime in *TBX5*[in/del] cells (rho≥|0.4|, p-value<0.05), but not in wildtype cells (Z-score≥15) (Fig. 2j, Extended Data 5), signifying that these genes are

140   inappropriately deployed in *TBX5*[in/del] cells.

       To identify genes that may determine one cell trajectory route from another, we

142   assessed differential gene expression between imputed intermediates, which we considered as potential precursors, within branches proximal to *TBX5* genotype-specific tips. We compared

144   these intermediate branches of cells that distinguish the cell trajectory route to CMs of wildtype, control and *TBX5*[in/+] from *TBX5*[in/del] (Fig. 2k, segments 69 vs. 70). We identified several

146   differentially expressed genes, including structural genes (e.g. *MYL3*, *TTN*, *MYH6*, *TNNT2*, *TNNI1*; adj p-value<0.05 by Wilcoxon Rank Sum test), calcium handling genes (*PLN*, *ATP2A2,*

148   *RYR2*; adj p-value<0.05)*,* secreted factors (*WNT2*, *FGFR1*; adj p-value<0.05), and cardiac TFs (*IRX4*, *HAND2*; adj p-value<0.05*)* (Extended Data 5). Of note, expression of the CHD-

6

150   associated cardiac transcription factor *NKX2-5*, a transcriptional partner of TBX5 [7,27,28], was

differentially expressed between intermediate branches of the URD tree that distinguish

152   wildtype/control/*TBX5$^{in/+}$ TNNT2$^+$* cells from *TBX5$^{in/del}$ TNNT2$^+$* cells (Fig. 2l; adj p-value<1E-300

by Wilcoxon Rank Sum test). Onset of *NKX2-5* expression was delayed in *TBX5$^{in/del}$* cells (adj p-

154   value<0.05 by Bonferroni-Holm multiple testing correction), along with a module of genes (e.g.

PARP1, RPL37, KIAA1462 and *ATP1A1*; adj p-value<0.05), concomitant with *NKX2-5*

156   expression (Fig. 2l, Extended Data 5), providing a potential molecular explanation for a delay of

onset of beating by *TBX5* loss (Fig. 1e).

158

Quantitative transcriptomic responsiveness to reduced TBX5 dosage in cardiomyocytes

160   *TBX5* genotype-specific clusters emerged among cardiomyocytes at d11 (Fig. 2c), and

TBX5 genotype-specific segregation was more striking at d23, particularly in *TNNT2$^+$* cells (Fig.

162   2d). We focused on *TNNT2$^+$* clusters at d23 (Fig. 3a, b) and d11 (Extended Data 6). We

constructed a phylogenetic tree relating 25 different *TNNT2$^+$* cell clusters (Fig. 3c), and

164   observed heterogeneity of gene set enrichment among WT or *TBX5$^{in/+}$* clusters (Fig. 3d),

implying putative CM subtypes. Some CM subtypes did not fit conventional categorization

166   based on anatomy. We searched for differentially expressed genes, by pair-wise comparisons

of related subtypes between *TBX5* genotypes. To identify *TBX5* genotype-specific differences

168   within a CM subtype, we compared clusters enriched for WT to related clusters enriched for

TBX5$^{in/+}$ or *TBX5$^{in/del}$* cells (Fig. 3d-k). We discovered only a few common changes in gene

170   expression amongst pair-wise cluster comparisons of WT vs *TBX5$^{in/+}$* clusters, such as *NPW*

and *PLN* (Fig. 3d-i; adj p-value<0.05 by Wilcoxon Rank Sum test). We also discerned

172   differences in gene expression based on cluster-specific comparisons (adj p-value<0.05 by

Wilcoxon Rank Sum test), implying discrete cell subtype-sensitivity to TBX5 haploinsufficiency

174   (Fig. 3d-i) or *TBX5* loss (Extended Data 7). We also compared related *TBX5* genotype-specific

cell clusters at a lower resolution of Louvain clustering and discovered genes that were

176   differentially expressed across reduced TBX5 dosage in a variety of patterns (Fig. 3j, k).

Quantitative changes in gene expression level were apparent across *TBX5* genotypes (for

178   example, *PLN, FYXD1*; adj p-value<0.05 by Wilcoxon Rank Sum test), as were changes in both

expression level and percentage of expressing cells (e.g. *RSPO3, NPPA, TECRL, DES*) (Fig.

180   3k)*.*

This differentially expressed gene set was enriched for electrophysiology (EP)-related

182   genes (FDR<0.05, Fig. 3l), which are implicated in membrane depolarization (*SCN5A*), calcium

handling (*RYR2, ATP2A2,* and *PLN*) and arrhythmias (*TECRL*) (Fig. 3e, g, i, k, l). Several

184   altered transcripts were encoded by other genes implicated in CHD (*CITED2, MYOCD,*

ANKRD1) (Fig. 3e, g, i, k, l). Some TBX5-dependent genes that were previously associated with

186   CHD or arrhythmias by genome-wide association studies (GWAS) were identified (Fig. 3l). We

uncovered *IGFBP7, FRAS1, MYH7B* and *SMCHD1* for CHD (odds ratio 3.2, FDR<0.03) and 47

188   reported genes for arrhythmias (for example, *PLN, HCN4, SCN5A, GJA1*, *PITX2* and *TECRL*;

odds ratio 9.0, FDR<1.9E-39) among TBX5-sensitive genes at day 23 (Fig. 3m, Supplementary

190   Table 2).

Using orthogonal assays at single cell resolution, we found that *TBX5* dosage-

192   dependent downregulation of *NPPA* was evident in CMs by RNAscope (*TBX5$^{in/+}$*, p<0.05;

TBX5$^{in/del}$ or *TBX5$^{PuR/PuR}$*, p<1E-4 by Student's t-test), consistent with a TBX5-dependent

194   rheostatic regulation of this gene in mouse [7,8]. Loss of DES in *TBX5$^{in/+}$* and recovery in *TBX5$^{in/del}$*

was detected in CMs by flow cytometry (Extended Data 8, p-value<1E-4 by Chi-Square test),

196   corroborating some human *TBX5* dose-dependent sequelae.

Comparisons of biological replicates at d23 showed significant overlap of TBX5-

198   dependent genes for WT vs. *TBX5$^{in/+}$* (p-value<2.466e-9 by hypergeometric test) or WT vs.

TBX5$^{in/del}$ (p-value<5.410e-6) (Extended Data 9, 10). The differences in gene expression

200   between biological replicates likely reflect a combination of technical variability and biological

stochasticity that, as in patients with *TBX5* mutations, may explain variable expressivity of

202   disease for a given mutation. Since modifiers in different genetic backgrounds might modulate

phenotypic effects, we assessed iPSC lines of *TBX5* mutants in an independent genetic

204   background (PGP1, from a Caucasian male, compared to WTC11 from a Japanese male,

Extended Data 11). Comparisons of TBX5-dependent genes in d23 *TNNT2*⁺ cells showed

206   significant overlap between WTC11 vs. *TBX5$^{in/+}$* and PGP1 vs. *TBX5$^{in/+}$* (p-value<1.174e-8 by

hypergeometric test) or WTC11 vs *TBX5$^{in/del}$* and PGP1 vs. *TBX5$^{del/del}$* (p-value<7.260e-15)

208   (Extended Data 11, 12), proportionally similar to biological replicates (Extended Data 9, 10).

These results demonstrate reproducible TBX5 dosage-dependent alterations from independent

210   experiments, genetic backgrounds, and gene targeting strategies.

To assess if changes to TBX5 dose-sensitive genes were largely direct or indirect TBX5

212   targets, we examined TBX5 occupancy in human iPSC-derived CMs from a published dataset

[10]. We found correlations of TBX5 occupancy near TBX5 dosage-vulnerable gene sets (Fig. 3l,

214   m, and Extended Data 13, 14; for example, odds ratio 6.9 for all TBX5-dependent human

genes; FDR<1.9E-178), suggesting our identified genes may be direct TBX5 targets. TBX5

216   cooperates with GATA4 for cardiac gene regulation [10,28,29]; we also observed that GATA4

occupancy [10] with TBX5 was highly associated near TBX5-dependent genes (Fig. 3l, m, and

218   Extended Data 13, 14; for example, odds ratio 6.4 for all TBX5-dependent human genes;

FDR<1.3E-155), indicating that GATA4 may have a role modulating TBX5 dosage-sensitive

220   genes.

222   **Susceptible human gene regulatory networks for congenital heart disease**

Since CHD-associated and arrhythmia-related genes were enriched among TBX5-

224   dependent genes, we deduced that TBX5 may be vital for preserving the integrity of cardiac

gene regulatory networks (GRNs). To evaluate the role of TBX5 dosage for regulating GRNs,

9

226   we used bigSCale2 [30] to independently infer putative GRNs from single cell expression data of

TNNT2+ cells at d6, d11 and d23 of each *TBX5* genotype (Fig. 4a, b, Extended Data 15). This

228   allows for quantitative prediction of the biological importance of genes in a regulatory network

reconstructed with bigSCale2, by applying the concept of "pagerank" [30], first devised to rank the

230   importance of websites via numerical weighting [31], to discover genes with a loss in importance

(i.e. centrality) among *TBX5* genotypes. By comparing nodes from inferred networks of WT to

232   *TBX5*$^{in/+}$ or *TBX5*$^{in/del}$, we uncovered several nodes that displayed reduced pagerank centrality at

specific time points and levels of reduced TBX5 dosage (Fig. 4a-c, Extended Data 15). These

234   included *RYR2* and twenty CHD-associated genes (for example, *GATA6*, *HAND2*, *SMAD2,*

p<2.2e-5 by hypergeometric test,) (Fig. 4c, d, Extended Data 15), consistent with independent

236   analysis from differential gene expression. For example, at d11, pagerank centrality of the CHD-

associated TF *SMAD2* was absent in *TBX5*$^{in/+}$ cells (Fig. 4a-c, top 5% of all changes), indicating

238   an impairment of *SMAD2* function. Centrality of the cardiac development-related TF *MEF2C*,

which is necessary for heart development [32], was substantially reduced by heterozygosity or

240   loss of *TBX5* at d11 (Fig. 4a-c, top 5% cutoff). *MEF2C* gene expression was unchanged by

reduced TBX5 dosage, suggesting a change in *MEF2C* functional connectivity. These altered

242   GRNs show that TBX5 dosage is critical for maintaining cardiac network stability, and unveil

potential genetic interactions disrupted in TBX5-dependent CHDs.

244   To further investigate the predicted relationship between *TBX5* and *MEF2C* within a

dosage-sensitive CHD-associated GRN, we used a complementary approach using bigSCale2,

246   to identify gene-gene correlations with *TBX5* expression in individual *TNNT2*+ cells across

timepoints and *TBX5* genotypes (Fig. 4e). Genes highly co-expressed with *TBX5* (Pearson

248   coefficient >0.5) regardless of *TBX5* genotype suggested potential cell autonomous effects by

TBX5 dosage (for example, *PLN*, *RYR2*, *TTN*), while those with high anti-correlation (Pearson

250   coefficient <-0.5) suggested non-cell autonomous effects (for example, *HES1, TLE1, CBX1,*

10

ETV4, ID4, FGFR1). *MEF2C* expression was among the highest correlated with *TBX5*

252   expression and demonstrated greatest *TBX5*-dependent decrease of pagerank (Fig. 4c, e) or

degree (i.e. putative number of target genes, Supplemental Table 3) at d11, further suggesting

254   *MEF2C* as a candidate for mediating TBX5 dose-sensitive regulatory effects. Multiple genes

that correlated with *MEF2C* displayed diminished levels of degree by reduced TBX5 dosage (for

256   example, *SMYD1, PDK1, MYOCD, TTN, RYR2*; top 5% cutoff) (Fig. 4f, Supplementary Table

3), supporting a potential explanation for changes to *MEF2C* functional connectivity in a TBX5

258   dosage-sensitive GRN.

We evaluated the predicted genetic interaction between *TBX5* and *MEF2C in vivo*. We

260   used a hypomorphic allele of *Tbx5* (*Tbx5^{CreERT2IRES2xFLAG}*, abbreviated *Tbx5^{CreERT2}*) [33], which we

further characterized (Extended Data 16) to probe for a potentially highly-sensitive genetic

262   interaction between *Tbx5* and a null allele of *Mef2c (Mef2c^{del})* [32]. *Tbx5$^{CreERT2/+}$;Mef2c $^{del/+}$* mice

were underrepresented at weaning (Fig. 5a). By histology, we detected muscular (n=3 of 4) or

264   membranous (n=1 of 4) VSDs in compound heterozygous embryos at E14.5, which were not

apparent in *Tbx5$^{CreERT2/+}$* or *Mef2c $^{del/+}$* embryos (Fig. 5b-k). These findings demonstrate a highly-

266   sensitive genetic interaction between *Tbx5* and *Mef2c* in mouse *in vivo*, consistent with

prediction from the human TBX5 dose-sensitive GRN.

268   We speculated that MEF2C may play a direct role to co-regulate TBX5-dependent gene

expression. Chromatin occupancy [34] of TBX5, MEF2c, and MEF2a (also predicted to be part of

270   the TBX5-dependent GRN) was highly correlated near TBX5-sensitive human or mouse genes

(for example, *HAND2, FHL2, TECRL, NPPA*/*NPPB*; Fig 5i-q, Extended Data 17, 18, 19;

272   FDR<0.05 for multiple comparisons). Thus, direct co-regulation of target genes by TBX5,

MEF2c, and MEF2a, in addition to previously known interactions with NKX2-5 and GATA4, may

274   be a potential TBX5 dosage-dependent mechanism for CHDs.

11

276   **Discussion**

        Our studies with a human cellular model of CHD has defined consequences of reduced

278   TBX5 dosage during cardiac differentiation at single cell resolution. Of potential relevance to a

        range of anatomical and functional manifestations of *TBX5* haploinsufficiency, we uncovered

280   discrete responses to reduced TBX5 dosage in susceptible cardiomyocyte subtypes. The

        quantitative specificity of TBX5-dependent cell types underscores cellular complexity in

282   response to transcription factor dosage. Analysis of human TBX5 dose-sensitive GRNs

        identified vulnerable nodes enriched for CHD-associated or cardiac development genes,

284   suggesting a vital role for TBX5 dosage to maintain cardiac network stability. The sensitivity of a

        GRN to transcription factor dosage has been observed in *Drosophila* embryo patterning [35] for

286   example, but has not been linked to human disease to date. The biophysical rules regulating

        transcription factor dosage sensitivity are only now becoming understood, and our results in a

288   human CHD model may bring immediate pertinence of human disease to this biological context.

        From TBX5-sensitive GRNs, we discovered several important nodes linking many CHD-

290   related genes. For example, the reduced centrality of *MEF2C* in the TBX5-dependent GRN

        suggests an important and sensitive link between these cardiac transcription factors. Indeed, we

292   validated this predicted genetic interaction in mouse, which yielded muscular VSDs, a type of

        CHD rarely observed in mouse models but common in humans. It is likely that other sensitive

294   nodes in a TBX5-dependent network will illuminate novel aspects of CHD and cardiac gene

        regulation. Variability in CHDs with monogenic inherited or *de novo* mutations could be

296   explained by additional mutations in genes that form part of these functional networks, as

        illuminated by our findings, and as evidenced by oligogenic inheritance of CHD-causing variants

298   [11]. Our results point to a genomic framework that will guide genetic insights into the

        underpinnings of CHD.

300

Contributions. I.S.K. and B.G.B conceived and designed the project. B.I.G., L.W., L.B., T.S.

302   and I.S.K. performed gene targeting and isolation of mutant iPSCs. B.I.G., K.S.R, P.G., T.S.,

and I.S.K. performed in vitro differentiation and harvested samples. P.G. performed the

304   Western analysis. M.H.L. performed electrophysiology analyses. R.T. performed statistical

analyses for electrophysiology. K.S.R. performed immunostaining and scoring of

306   cardiomyocytes. G.A.A. performed RNAscope and flow cytometry. K.S.R. and I.S.K. performed

Seurat analyses. K.S.R., A.P.B., H.G., and I.S.K. performed pseudotime analyses. H.G.

308   implemented the cell browser. G.I. performed gene regulatory network analyses. W.P.D. and

I.S.K. performed phenotype analyses of mutant mice. I.S.K. performed bulk RNAseq analyses.

310   B.N.A., F.G., K.L., and W.T.P. performed ChIP-seq experiments and peak calling. S.K.H. and

R.T. performed association analyses of co-occupancy, gene expression and disease

312   candidates. J.M.S., W.T.P., C.E.S., J.G.S., and H.H. provided advisement. I.S.K. and B.G.B.

wrote the manuscript, with comments and contributions from all authors.

314

342   **Competing Interests**: B.G.B. is a co-founder and shareholder of Tenaya Therapeutics. None of

        the work presented here is related to the interests of Tenaya Therapeutics.

14

Methods

Gene targeting and genotyping of human iPS cells mutant for *TBX5*. sgRNAs for *TBX5*

exon 3 (sgRNA1, TCCTTCTTGCAGGGCATGGA) or exon 7 (sgRNA2,

CCTTTGCCAAAGGATTTCG), which encode the T-box domain, were selected using

crispr.genome-engineering.org, and cloned by annealing pairs of oligos into a plasmid

containing humanized *S. pyogenes* Cas9, as described in [36] (px330-U6-Chimeric_BB-CBh-

hSpCas9 was a gift from Feng Zhang, Addgene #42230).

For WTC11-derivatives *TBX5^{+/+}* (control), *TBX5^{in/+}* or *TBX5^{in/del}*, the induced pluripotent

stem (iPS) cell line WTC11 (gift from Bruce Conklin, available at NIGMS Human Genetic Cell

Repository/Coriell #GM25236) [37] was electroporated (Lonza #VPH-5012) with a cloned

nuclease construct containing a guide RNA (sgRNA1) targeting exon 3 of *TBX5*, as described in

[37,38]. Cells were plated on human ESC-grade Matrigel (Corning #354277) and cultured in

mTeSR-1 (StemCell Technologies Cat #05850) with 10μM ROCK inhibitor (StemCell

Technologies, Y-27632). For screening of *TBX5* exon 3 non-homologous end-joining (NHEJ)

mutations, genomic DNA flanking the targeted sequence was amplified by PCR (For1:

ATGGCATCAGGCGTGTCCTATAA and Rev1: CCCACTTCGTGGAATTTTAGCCA), amplicons

underwent digestion by NlaIII, and then evaluated for loss of NlaIII by gel electrophoresis

(wildtype band 800bp, mutant band 880bp). Clones with no change, a heterozygous or

homozygous loss of NlaIII were sequenced (For1: ATGGCATCAGGCGTGTCCTATAA, Rev1:

TTCCGGGCTTGAACTTCTGG, Seq1: ATAGCCTTGTGCTGATGGCA).

For generation of *TBX5^{PuR/PuR}*, a puromycin resistance gene cassette (Frt-PGK-EM7-

PuroR-bpA-Frt) containing homology arms of 469bp (5' homology arm) and 466bp (3'

homology arm) around the sgRNA1 target site at +9bp from the start of *TBX5* exon 3 was

cloned by Cold Fusion (System Biosciences #MC010B) using amplicons from genomic DNA of

WTC11 into a construct that was a modification of plasmid pEN114[39]. WTC11 cells were

electroporated with a cloned nuclease construct containing a guide RNA targeting exon 3, along

374   with the *TBX5* exon3 homology arm-Frt-PGK-EM7-PuroR-bpA-Frt cassette and plated as a

serial dilution in mTeSR-1 with Rock inhibitor, as described in [38]. On day 2 and subsequent

376   days, cells were grown in media containing mTeSR-1, Rock inhibitor and puromycin (0.5ug/mL),

to select for puromycin-resistant cells. For screening of *TBX5* exon 3 homology-directed repair

378   (HDR) mutations, genomic DNA flanking the targeted sequence was amplified by PCR (For1:

ATGGCATCAGGCGTGTCCTATAA, and Rev2: CCCACTTCGTGGAATTTTAGCCA for

380   wildtype, 797 bp, For1: ATGGCATCAGGCGTGTCCTATAA, Rev3:

GTTCTTGCAGCTCGGTGAC [39] for PuroR, 1631 bp). Positive 5' arm clones were genotyped by

382   PCR for the 3' arm (For2: ATTGCATCGCATTGTCTGAG [39], Rev4:

TTTGACAATCGGGTGGGACC, 829 bp).

384   For PGP1-derivatives *TBX5*^{in/+} or *TBX5*^{del/del}, the iPS cell line PGP1 (gift from George

Church, available at NIGMS Human Genetic Cell Repository/Coriell #GM23338) [40] was

386   electroporated with a cloned nuclease construct containing a guide RNA (sgRNA2) targeting

exon 7 of *TBX5*, as described in [41]. For screening of *TBX5* exon 7 NHEJ mutations, the targeted

388   sequence was amplified using PCR primers (For3: GCTTCTTTTGGTTGCCAGAG, Rev5:

CATTCTCCCCATTTCCATGT, Seq2: AGAGGCTGCATTTCCATGAT), Illumina compatible-

390   libraries from clones were generated and multiplex-sequenced on a MiSeq for purity of

homogeneity of clones for heterozygous or homozygous mutations, as described in [41].

392

Isolation of homogenous iPS cell clones. Isolation of homogenous colonies for WTC11-

394   derivatives *TBX5*^{+/+} (control), *TBX5*^{in/+} or *TBX5*^{in/del} was performed by modification of methods

described previously [38,42]. Briefly, single cell suspension of electroporated iPS cells was plated

396   on Matrigel-coated 6 well plates (WP) (BD Bioscience #351146). Once cultures were adherent

and recovered to ~80% confluency, cells were detached by Accutase Cell Detachment Solution

398   (Stemcell Technologies #07920), diluted with 1X DPBS without Ca^{2+}/Mg^{2+} and singularized

16

using a P1000 filtered tip, and centrifuged. The cell pellet was resuspended in mTeSR-1, Rock

400   inhibitor and Gentamicin (Life Technologies #15750-060) media, incubated with DAPI (1:1000

from a 1mg/mL stock) for 5 min, centrifuged and resuspended at a concentration of at least

402   1.0E6 cells/mL in mTeSR-1, Rock inhibitor and Gentamicin media without DAPI. After filtering

cells with a 40-micron mesh into FACS tubes, remaining cells (about 120,000 cells per well)

404   were plated on to 6WP for maintenance. Single cells were then sorted for DAPI negativity using

a BD FACS AriaII or AriaIII, with a 100-micron nozzle at the lowest flow rate available, into

406   individual wells of a 96WP coated with Matrigel containing media of mTeSR-1, Rock inhibitor

and Gentamicin. Upon recovery at 37°C, each well was evaluated one day later for no cells, one

408   cell or more than one cell. All cells were maintained with mTeSR-1, Rock inhibitor and

Gentamicin media for at least 5 days, then with mTeSR-1 alone for an additional 5-7 days. Each

410   well at 25% confluency was harvested and re-plated upon singularization with P200 tips in

96WP for more efficient cell growth. When the cell confluency of each well from "single" cells

412   was nearly 100%, then 90% of cells were harvested for genotyping using QuickExtract DNA

lysis solution (Epicentre #QE0905T), while 10% of cells were re-plated for the next round of cell

414   selection for wells of interest by FACS sorting again or by serial dilution of cells for manual

picking of colonies, as described in [37,38] from apparent "single" cells. Rounds were repeated until

416   every daughter well showed the same genotype, consistent with homogeneity. Genomic DNA

from individual wells of interest were amplified using high fidelity *Taq* polymerase, TA-cloned

418   and sequenced to confirm genotype and homogeneity.

Isolation of a homogenous colonies for PGP1-derivatives *TBX5$^{in/+}$* or *TBX5$^{del/del}$* was

420   performed, as described in {Byrne:2007fn}. Isolation of a homogenous colonies for WTC11-

derivative *TBX5$^{PuR/PuR}$* was performed, as described in [38].

422   After sequencing confirmation of respective genotypes, karyotypically-normal cells from

each iPS cell line were expanded for subsequent studies.

424

17

Maintenance of iPS cells and differentiation to cardiomyocytes. All iPS cell lines were

426   transitioned to and maintained on growth factor-reduced basement membrane matrix Matrigel

(Corning #356231) in mTeSR-1 medium. For directed cardiac differentiations, iPS cells were

428   dissociated using Accutase and seeded on to 6WP or 12WP. The culture was allowed to reach

80-90% confluency and induced with the Stemdiff Cardiomyocyte Differentiation Kit (Stemcell

430   Technologies #05010), according to the manufacturer's instructions. Starting on day 7,

differentiations were monitored daily for beating cardiomyocytes and onset of beating was

432   recorded as the day when beating was first observed.

434   **Flow Cytometry.** iPS-derived cardiomyocytes from WTC11, Control, $TBX5^{in/+}$ and $TBX5^{in/del}$

lines were dissociated using Trypsin-EDTA 0.25% on day 15 or day 23 after induction of the

436   differentiation protocol and fixed with 4% methanol-free formaldehyde. Cells were washed with

PBS and permeabilized using FACS buffer (0.5% w/v saponin, 4% Fetal Bovine Serum in PBS).

438   For evaluation of differentiation efficiency, cells were stained with a mouse monoclonal antibody

for cardiac isoform Ab-1 Troponin at 1:100 dilution (ThermoFisher Scientific #MS-295-P) or the

440   isotype control antibody (ThermoFisher Scientific #14-4714-82). For analyzing levels of Desmin

protein, cells were co-stained with the mouse monoclonal antibody for cardiac isoform Ab-1

442   Troponin at 1:100 dilution and recombinant rabbit anti-Desmin antibody at 1:70 dilution (Abcam

#ab32362), or normal rabbit IgG antibody (Millipore Sigma #NI01) for 1 hour at room

444   temperature. After washing with FACS buffer, cells were stained with the following secondary

antibodies - goat anti-mouse IgG Alexa 594 at 1:200 dilution (ThermoFisher Scientific #A-

446   11005) and donkey anti-rabbit IgG Alexa 488 at 1:200 dilution (ThermoFisher Scientific

#A21206) for 1 hour at room temperature. Cells were then washed with FACS buffer, stained

448   with DAPI for 5 minutes, rinsed, and filtered with a 40-micron mesh. At least 10,000 cells were

analyzed using the BD FACSAriaII or AriaIII, and results were processed using FlowJo (BD

450   Bioscience). Gating strategy is shown in Extended Data 20.

18

452   **Western blotting.** iPS-derived cardiomyocytes were harvested on day 15, pelleted and flash frozen. Protein was isolated from supernatant in RIPA buffer with EDTA-free protease and

454   phosphatase inhibitor (ThermoFisher Scientific) after sonication (15 second pulse on, 15 second pulse off, for four pulses). After quantification by BCA assay (ThermoFisher Scientific), 150µg of

456   total protein was loaded per well for each genotype. After running on SDS-PAGE and wet transfer with NuPage Transfer buffer (ThermoFisher Scientific) to a PVDF membrane, the blot

458   was washed in PBST and incubated in primary antibodies of rabbit polyclonal anti-TBX5 at a 1:400 dilution (Sigma #HPA008786) and mouse monoclonal anti-cTNT at 1:1000 dilution

460   (ThermoFisher Scientific #MS-295-P), followed by secondary antibody incubation with donkey anti-rabbit IgG IRDye680 at 1:2000 dilution (Licor #926-68073) and donkey anti-mouse IgG

462   IRDye800 at 1:2000 dilution (Licor #926-32212). The blot was imaged on an Odyssey FC Dual-Mode Imaging system (Licor).

464

   Fluorescent *in situ* hybridization. iPS cell-derived cardiomyocytes from WTC11, Control,

466   *TBX5$^{in/+}$*,*TBX5$^{in/del}$* and *TBX5$^{PuR/PuR}$* were dissociated using Trypsin-EDTA 0.25% on day 23 after induction of the differentiation protocol, and 25,000-40,000 cells were plated on to 8-well

468   chambered slides (Ibidi #80826), to obtain a relatively sparse monolayer of cardiomyocytes. Cells were fixed the following day with 10% Neutral Buffered Formalin for 15 minutes at room

470   temperature. Cells were then serially dehydrated in 50%, 70% and 100% ethanol and stored at -20°C until ready to be hybridized. *In situ* hybridization was performed using the RNAscope

472   Multiplex Fluorescent v2 Assay kit (Advanced Cell Diagnostics #323100) with probes for *Hs-TNNT2* (#518991) and *Hs-NPPA* (#531281). Slides were imaged at 10X and 40X magnification

474   on the Keyence BZ-X710 All-in-One Fluorescence Microscope. Mean intensity of *NPPA* signal was measured in each *TNNT2*+ cell from every group. Unpaired t-tests were used to calculate

476   statistical significance.

19

478   **Replating cardiomyocytes for single cell electrophysiology.** iPS cell-derived

cardiomyocytes (day 15 or older) from WTC11, Control, *TBX5$^{in/+}$*, *TBX5$^{in/del}$* and *TBX5$^{PuR/PuR}$*

480   were gently dissociated in Trypsin-EDTA 0.25% and quenched using StemDiff Maintenance

Medium with 10% FBS. Cell suspension was centrifuged at 800 rpm for 5 minutes. The pellet

482   was resuspended in StemDiff Maintenance Medium with Rock inhibitor at a 1:1000 dilution.

Cardiomyocytes were counted, and 25,000-35,000 cells were plated on to growth factor-

484   reduced Matrigel-coated 15mm round glass coverslips (Warner Instruments #64-0703) to obtain

a sparse distribution. Cardiomyocytes were then maintained on coverslips in StemDiff

486   Maintenance Medium.

488   **Patch Clamp Electrophysiology.** Patch clamp recordings were made on single iPSC-derived

CMs using the perforated-patch configuration. Experiments were performed at 30°C under

490   continuous perfusion of warmed Tyrode's solution containing (in mM): 140 NaCl, 5.4 KCl, 1

CaCl$_2$, 1 MgCl$_2$, 10 glucose, and 10 HEPES, with the pH adjusted to 7.4 with NaOH.

492   Recordings were conducted using borosilicate glass pipettes (Sutter Instruments) with typical

resistances of 2 to 4MΩ. The pipette solution consisted of (in mM): 150 KCl, 5 NaCl, 5 MgATP,

494   10 HEPES, 5 EGTA, 2 CaCl$_2$, and 240 µg/mL amphotericin B, with the pH adjusted to 7.2 with

KOH. Spontaneous action potentials were acquired in a zero-current current clamp

496   configuration using an Axopatch 200B amplifier and pClamp 10 software (Axon Instruments).

Data was digitized at 20 kHz and filtered at 1kHz. Action potential parameters from each cell

498   were derived using Clampfit 10 software (Axon Instruments).

500   **Fluorescent recordings of calcium flux.** iPSC-derived CMs on glass coverslips were loaded

with Ca^{2+} indicator dye Fluo-4 AM (Thermo Fisher Scientific #F14201) to record Ca^{2+} flux, as

20

502   previously described [43]. Measurements were made on spontaneously firing single or small

clusters of iPSC-derived CMs using a 10X objective on a Zeiss Axio Observer Z1 inverted

504   microscope. For experiments, cells were placed in Tyrode's solution containing 1.8 mM Ca^{2+}

within a 37°C heated stage-top imaging chamber (Okolab). Images were acquired at 100 fps

506   using an ORCA-Flash 4.0 camera (Hamamatsu, Bridgewater, NJ). Data was processed using

ZEN (Zeiss) or Image J software (http://rsbweb.nih.gov/ij/) and analyzed using custom in-house

508   software [44].

510   **Graphing and statistics for electrophysiology.** For electrophysiology and calcium imaging

experiments, graphs were generated using Prism 8.2.0 (GraphPad Software). Significance

512   between parental and experimental groups was determined with a custom R-script using

unpaired two-sided Welch's t tests with Holm-Sidak correction for multiple comparisons [12].

514   Adjusted $P < 0.05$ was considered statistically significant.

516   **Immunostaining and scoring of cardiomyocytes.** iPSC-derived cardiomyocytes from

WTC11, Control, TBX5$^{in/+}$ and *TBX5$^{in/del}$* were replated on coverslips placed in 12-well plates on

518   day 23, as described above for replating for electrophysiology. Cells were fixed in 4%

formaldehyde for 20 minutes at room temperature, followed by washes in PBS. Cells were then

520   treated with a blocking buffer containing 5% goat serum and 0.1% Triton X-100 in PBS for 1

hour at room temperature. A mouse monoclonal antibody for cardiac isoform Ab-1

522   Troponin (ThermoFisher Scientific #MS-295-P) was added to the coverslip-containing wells at a

1:100 dilution in blocking buffer and incubated on a rocker for 2 hours at room temperature.

524   Following washes with 0.1% Triton X-100 in PBS, coverslips were treated with a donkey anti-

rabbit IgG Alexa 488 antibody (ThermoFisher Scientific #A21206) at a 1:200 dilution for 2 hours

526   at room temperature. Coverslips were then washed with 0.1% Triton X-100 in PBS and stained

528   with DAPI at a 1:1000 dilution for 2 minutes. Coverslips were washed and stored in PBS at 4C.

Images were acquired on a Zeiss LSM 880 with Airyscan and processed by ImageJ [45].

Myofibrillar arrangement in cardiomyocytes was manually scored on a scale of 1-5,

530   similar to [46]. A score of 1 represents cells with intact myofibrils in a parallel arrangement. A

score of 2 represents cells that have intact myofibrils, but many are not parallel. Scores of 3 and

532   of 4 include cells with increasing degrees of myofibrillar fragmentation or aggregation. A score

of 5 represents cells without visible myofibrils. No cells were apparent among our samples with

534   a score of 5. Violin plots were generated in Prism (GraphPad) to show distribution of scored

cells from each group. Fisher's exact test was used to determine statistical significance.

536

Cell harvesting for single cell RNAseq. Cells from day 6, day 11 or day 23 of the

538   differentiation protocol were collected from 3 independent differentiations. Wells for dissociation

were chosen based on typical differentiated morphology on day 6 or robust beating on day 11

540   and day 23. Cells were singularized with Trypsin-EDTA 0.25%. After quenching, the single cell

suspension was centrifuged at 800 rpm for 5 minutes. The pellet was resuspended in 1X PBS

542   with 0.04% w/v Ultrapure BSA (MCLAB #UBSA-500) and counted. A 30μL cell suspension

containing 10,000 cells was used to generate single cell droplet libraries with the Chromium

544   Single Cell 3′ GEM, Library & Gel Bead Kit v2 according to manufacturer's instructions (10X

Genomics). After KAPA qPCR quantification, a shallow sequencing run was performed on a

546   NextSeq 500 (Illumina) prior to deep sequencing on a NextSeq 500, HiSeq 4000, or NovaSeq

(Illumina) for a read depth of >100 million reads per cell.

548

Data processing using Cellranger. All datasets were processed using Cellranger 2.0.2.

550   FASTQ files were generated using the mkfastq function. Reads were aligned to hg19 reference

(version 1.2.0). Cellranger aggr was used to aggregate multiple GEM libraries.

552

Seurat analysis. Outputs from the Cellranger pipeline were analyzed using the Seurat package

554 (version 2.3.4) in R (version 3.5.1) [R Core Team (2018). R: A language and environment for

statistical computing. R Foundation for Statistical Computing, Vienna, Austria.

556 URL https://www.R-project.org/]. Datasets from day 6, day 11 or day 23 experiments were

analyzed as separate Seurat objects. Quality control steps were performed to remove dead

558 cells or doublets, and cells with a UMI count between 10,000 to 80,000 were retained. After

normalizing the data, sources of unwanted variation, such as differences in the number of UMI,

560 number of genes, percentage of mitochondrial reads and differences between G2M and S

phase scores were regressed using the ScaleData function. Next, principal component analysis

562 (PCA) was performed using the most highly variable genes. Cells were then clustered based on

the top 25-30 principal components and visualized using a dimensionality reduction method

564 called Uniform Manifold Approximation and Projection (UMAP) [47]. The resolution parameter was

set, so that cluster boundaries separated the major cell types.

566 For day 11 or day 23 cardiomyocyte datasets, $TNNT2^+$ clusters were defined as

containing a majority of cells expressing *TNNT2* on a feature plot and extracted using the

568 SubsetData function and re-clustered. Subsequently, the resolution parameter was set to

partition clusters enriched for a particular genotype. A phylogenetic tree was generated by

570 relating the "average" cell from each cluster by centroid analysis, using the BuildClusterTree

function. Differential gene expression tests were run between closely related clusters, using the

572 FindMarkers function with min.pct set to 0.1 and logfc.threshold set to 0.25. Selected

differentially expressed genes with an adjusted p-value less than 0.05 from the Wilcoxon Rank

574 Sum test were then displayed using the Dotplot function. As Seurat log normalizes gene

expression counts and scales values for each gene (mean is 0, std dev of +/-1), dot plots and

576 heatmaps are based on scaled expression values.

Major cell type categories were defined by their expression of certain marker genes -

578 cardiomyocytes (*TNNT2*), dividing cardiomyocytes (*CENPF+TNNT2*), fibroblasts (*COL1A1*),

23

endoderm (*TTR* alone or *TTR+AFP*) and endothelial cells (*PLVAP*). Clusters of cells not defined

580   by any of these markers were labeled as 'Others'. The numbers of cells in each major cell type

category in each genotype were then calculated. Sunburst plot was generated in Excel using

582   the percentage of cells in each cell type category per genotype. We used FindAllMarkers to

generate a list of top marker genes for each cluster and presented two selected genes in a dot

584   plot to display potential diversity of subtypes among these major cell types.

586

Congenital Heart Disease-Associated or Electrophysiology-Related Gene Lists and Cell-

588   **Type Expression**. A list of 376 CHD-associated candidate genes were manually curated from

[18-25], including inherited, *de novo*, syndromic or non-syndromic CHD-associated genes. A list of

590   76 EP-linked genes were manually curated. A list of cardiac development-related factors is from

[48]. Lists can be found in Supplementary Table 1.

592   To determine cell-type enrichment of each CHD-associated gene, cells in the day 23

dataset were assigned one of five cell-type labels (cardiomyocytes, fibroblasts, endoderm,

594   endothelial and others). A dot plot was generated to visualize the expression of CHD-associated

genes in the 5 cell types. Genes were first manually curated for enrichment in a certain cell type,

596   based on expression. Statistical significance of the enrichment of a certain gene in one cell type

over the others was then evaluated by Wilcoxon Rank Sum test (adjusted p-value < 0.05).

598

Cell trajectories and pseudotime analysis. Pseudotime analysis was performed using the

600   URD package (version 1.0.2). A single Seurat object with data from three timepoints and four

genotypes was processed, as described in the previous section, and then converted to an URD

602   object using the seuratToURD function. Cell-to-cell transition probabilities were constructed, by

setting the number of nearest neighbors (knn) to 211 and sigma to 8. Pseudotime was then

604   calculated by running 80 flood simulations with *POU5F1+* clusters as the 'root' cells. Next, all

24

606　day 23 clusters were set as 'tip' cells and biased random walks were simulated from each tip to build an URD tree.

608　　To identify genes that correlate with pseudotime in one genotype but not the other, we calculated Spearman rank correlation, using Python (v3.7.3, and libraries Pandas 0.25.0, Numpy 1.17.1, and SciPy 1.3.1), to find genes that share a significant monotonic relationship (p-610　value less than 0.05) with pseudotime. To determine if these monotonic relationships differ between WT and $TBX5^{in/del}$ paths to cardiomyocytes, we used a Fisher z-transformation to test 612　the null hypothesis that there is no significant difference in correlation [49]. To illustrate these results, we use a scatter plot for all genes with a significant rho value (p-value<0.05 by two-614　sided t test), or heat maps for genes with a |rho|≥0.4 to pseudotime and Z-score≥15 as a difference between WT and $TBX5^{in/del}$ paths.ki

616　　To identify differential expressed genes in inferred cardiac precursors (stems in the URD tree) that are affected by $TBX5$ loss, cell barcodes from each precursor segment (69 for 618　wildtype/control/$TBX5^{in/+}$ path and 70 for $TBX5^{in/del}$ path) were extracted from the URD object and assigned new identities in the corresponding Seurat object. Differential gene test was then 620　performed between the two segments using Wilcoxon Rank Sum test with min.pct set to 0.1 and logfc.threshold set to 0.25. Selected genes with an adjusted p-value less than 0.05 were plotted 622　on the URD tree to visualize their expression.

　　To compare the trident ($TNNT2^+$ distal branch for WTC11, control and $TBX5^{in/+}$) and fork 624　($TNNT2^+$ distal branch for $TBX5^{in/del}$) during pseudotime, we subdivided the pseudotime from the common branchpoint to the tips of the trident and fork into twenty uniform windows. Within each 626　window, we then calculated the t-test, difference of means, and fold change between the trident and fork for all genes. We filtered the statistics by gene-window combinations with p<0.05 after 628　Bonferroni-Holm multiple testing correction. Then, we hierarchically clustered the genes on t-test p-values and plotted statistics using the R pheatmap library.

630

25

Gene ontology analysis. Gene ontology analysis was performed using 2018 biological process terms from org.Hs.eg.db (v3.8.2) and clusterProfiler (v 3.12.0), with a significance threshold set at p-value<0.05. To prevent high false discovery rate (FDR) in multiple testing, we used the default cutoff for the estimated q-value<0.05. Figures were produced using Matplotlib (v3.1.0). Gene ratios indicate the number of differentially expressed genes that overlap with each GO term divided by the total number of differentially expressed genes. For comparing $TNNT2^+$ clusters at d23, enriched gene ontology (GO) terms were determined using genes computed from a one-versus rest differential test (logfc>0.25; adj p-value<0.05 by Wilcoxon Rank Sum test) among clusters that were predominantly composed of the same $TBX5$ genotype (WT-21, 12, 3, and Control-4, or $TBX5^{in/+}$- 9, 7, 6, and 0). Enriched GO terms associated with pseudotime in a WT- or $TBX5^{in/del}$ path were generated using genes positively correlated with pseudotime (rho≥|0.4|, and Z-score≥15) from each path. Several significant GO terms are highlighted.

Cell browser implementation. The cell browser at cells.ucsc.edu was developed by Maximilian Haeussler. We created a cell browser session that allows the user to interrogate the spatial distribution of metadata and expression across data, in multiple reduced dimensionality spaces including the URD trajectory. Using a Scanpy python pipeline, we generated PCA, tSNE, UMAP, PAGA, and drl transforms. We also imported the URD trajectory mapping and WGCNA transform from their respective packages. We ran the scoreCT algorithm to assign cell types to cell clusters using a marker gene set.

Gene regulatory network analysis. bigSCale2 (https://github.com/iaconogi/bigSCale2) [30] was used with default parameters to infer gene regulatory networks and "correlomes" from single cell RNAseq expression data for $TNNT2^+$ cells, simply passing as input expression counts and gene names. Details of each data set can be found in Supplementary Table 3. To evaluate significant

658   changes in pagerank (or degree) centrality, we computed all pairwise differential differences in pagerank (or degree) between baseline (wildtype or control) and *TBX5* mutants (*TBX5$^{in/+}$* or *TBX5$^{in/del}$*) (12 total differences, from 2 *TBX5* mutants * 2 baselines * 3 stages) and used these

660   values to determine the top 5% upper change cutoff from 8,704 genes of all networks. Classification of Pearson correlations were empirically chosen at >0.5 for correlation and <-0.05

662   for anti-correlation.

Mice. All mouse protocols were approved by the Institutional Animal Care and Use Committee

664   at UCSF. *Tbx5$^{del/+}$* [7] and *Tbx5^{CreERT2IRES2xFLAG}* (abbreviated here as *Tbx5^{CreERT2}*) [33] mice were described previously. *Tbx5$^{fl-bio/fl-bio}$*[50] mice were obtained from Frank Conlon. *Mef2c$^{del/+}$* mice [32]

666   were obtained from Brian Black. *Mef2a^{fl-bio}* and *Mef2c^{fl-bio}* (Jackson #025983) were described in [34]. *Rosa26BirA* mice were obtained from Jackson labs (Jackson #010920) [51].

668   **ChIP-seq.** Combined peaks of human TBX5 or GATA4 ChIP-seq from hiPSC-derived CMs were used [10]. bioChIP-seq of mouse TBX5, MEF2c and MEF2a from E12.5 hearts were from [34].

670   Single replicates of TF bioChIP peaks, which were IDR normalized (IDR_THRESHOLD=0.05 between each set of replicates), were defined as the summit of the peak with the strongest ChIP

672   signal ± 100bp of the individual replicate with the greatest peak intensity. Mouse H3K27ac ChIP-seq at E12.5 of embryonic cardiac ventricles was from [52].

674   **Bulk RNAseq analysis of embryonic mouse hearts.** Embryos at E10.5 from timed matings of *Tbx5$^{del/+}$* x *Tbx5$^{CreERT2/+}$* were harvested. Each whole heart was dissected, placed in Qiazol, and

676   homogenized with a 25-guage needle. Total RNA was extracted using the miRNeasy micro kit with on-column DNAse digestion (Qiagen) and assessed by bioanalyzer (Agilent) for RNA

678   integrity, as previously described [53]. Four individual hearts of each genotype (wildtype, *Tbx5$^{CreERT2/+}$*, *Tbx5$^{del/+}$* or *Tbx5$^{del/CreERT2}$*) from multiple litters were used as biological

680   quadruplicates. RNAseq libraries were generated using the Ovation RNA-seq system V2 kit

27

682 (NuGen), and SPIA-amplified cDNA was made using the Ovation Ultralow System V2 kit (NuGen). Libraries were evaluated by bioanalyzer (Agilent), quantified using KAPA qPCR (Kapa

684 Biosystems), and sequenced by paired-end 100 bp reads using a HiSeq2500 (Illumina), for a sequencing depth of >40 million reads per library. Reads were aligned to mm9 by TopHat2 [54]

686 and counts per gene were tallied by featureCounts [55]. Differentially expressed genes were identified by EdgeR[56], using cutoffs of log2 fold-change of >0.5 or <-0.5, and raw p-value <0.01.

688 R functions, K-means clustering and pheatmap, were used to cluster and create bulk RNAseq heatmaps.

690 **Statistical analyses for correlations.** We evaluated the pair-wise association among 24 variables, including all human genes, TBX5-dysregulated genes in cardiomyocytes from two

692 different stages of differentiation (d11 or d23), CHD-associated genes, EP-linked genes, TBX5 or GATA4 binding [10], and genome-wide association (GWAS) genes for CHDs or arrhythmias.

694 Reported GWAS genes from https://www.ebi.ac.uk/gwas/ for the terms congenital heart disease, congenital heart malformation, congenital left sided heart lesions, conotruncal heart

696 defect and aortic coarctation were used to define congenital heart disease-related (CHD) GWAS genes. Reported genes from terms such as cardiac arrhythmia, supraventricular ectopy,

698 ventricular ectopy, premature cardiac contractions, atrial fibrillation, sudden cardiac arrest and ventricular fibrillation were considered as arrhythmia-related (EP-GWAS) genes. Two nearest

700 genes within 100kb, by using GREAT (great.stanford.edu), of TBX5 or GATA4 binding sites or of reported genes from each group of GWAS were considered for the analysis. The natural

702 logarithm odds of genes associating with each one of these variables versus the odds of genes associating with every other variable were estimated using generalized linear models with

704 family="binomial" setting in R. The resulting significances of these natural log odds ratios were adjusted for multiple testing by the Benjamini-Hochberg method [57]. Significance was determined

706 using an FDR threshold of 0.05 or less.

708   Additional correlations were evaluated between 42 variables, including all mouse genes, mouse TBX5-dysregulated genes (from bulk RNAseq of E10.5 hearts from wildtype, $Tbx5^{del/+}$, $Tbx5^{CreERT2/+}$ or $Tbx5^{CreERT2/del}$ embryos), human TBX5-dysregulated genes from d11 or d23

710   cardiomyocytes, and TBX5, MEF2c or MEF2a binding sites from E12.5 mouse heart tissue [34]. Human gene symbols were converted to mouse gene symbols, using the getLDS() function

712   from the biomaRt package (https://www.r-bloggers.com/converting-mouse-to-human-gene-names-with-biomart-package/). Two nearest genes within 100kb of TBX5, MEF2c or MEF2a

714   binding sites were considered for the analysis.

716   For assessment of associations between binding locations of TBX5, MEF2c and MEF2a transcription factors with genes dysregulated by TBX5, analyses were performed corresponding to binding regions of each of the three TFs. First, binding regions of each TF was evaluated for

718   association with genes, defined by nearest two genes within 100kb. Using the list of TBX5-dysregulated genes (mouse or human), binding regions of each TF associated with a TBX5-

720   dysregulated gene was determined. Identified binding regions of each TF that overlapped with at least 50% of the binding regions of each of the other two TFs was determined, using bedops -

722   -element-of -50%. This approach defined three variables, including every binding region of the TF, if associated with a TBX5-dysregulated gene, or if it overlaps by at least 50% with the

724   binding region of the other TFs, that were used for logistic regression in R. The resulting changes in odds are represented as natural logarithm odds ratios. Multiple testing correction

726   was performed using the multtest package in R. All estimates are based on analyses for a given species (mouse or human TBX5-dysregulated).

728   **Data availability.** scRNAseq and bulk RNAseq datasets have been deposited at NCBI GEO, under accession GSE137876.

730   **Code availability.** R and python scripts will be available upon publication.

Figure 1. A human allelic series of *TBX5* mutants models features of congenital heart disease. a, Diagram of the human *TBX5* gene. Exons encoding the T-box domain of TBX5 are indicated in red. sgRNA1 was used to target exon 3 of *TBX5* by a CRISPR/Cas9 nuclease. **b**, Parental iPS cell line WTC11, control (CRISPR-treated, unmodified at exon 3 of *TBX5*) and targeted *TBX5* loss-of-function mutants (*TBX5^{in/+}*, *TBX5^{in/del}*, or *TBX5^{PuR/PuR}*) underwent directed differentiation to cardiomyocytes (CM) via mesoderm (MES) and cardiac precursor (CP) stages. **c**, TBX5 and cTNT protein expression for each *TBX5* genotype at day 15 (CMs). **d**, Differentiation efficiency by flow cytometry for cTNT+ cells (* p-value<0.05 by unpaired *t* test). **e**, Onset of beating (** p-value<0.01, *** p-value<0.001 by unpaired *t* test). **f-j**, Myofibrillar arrangement of cardiomyocytes (* p-value<0.05, **** p-value<0.0001 by Fisher's exact test). **k**,

36

884   Action potentials by patch clamp of single beating cells for each *TBX5* genotype. **l,** Action potential duration at 90% (APD$_{90}$) (* FDR<0.05). **m-n**, Traces of calcium transients from single

886   beating cells were analyzed, including time at 90% decay (t$_{90}$ down) (* FDR<0.05, ** FDR<0.01). Error bars represent standard deviation (**d, e**) or standard error (**l, n**) of the mean.

888

890

Figure 2. *TBX5* loss disturbs cell trajectories to cardiomyocyte fate. **a**, Cells of each *TBX5*
892   genotype were harvested at specific stages during directed differentiation to cardiomyocytes
(CM) for single cell RNAseq. **b-d,** UMAPs display cells at day 6, day 11 or day 23, colored by
894   *TBX5* genotype. A feature plot of the expression of the CM structural gene, *TNNT2*, is shown in
each inset. **e-g**, Reconstructed cell trajectories by the R package URD are shown as a
896   dendrogram for each *TBX5* genotype from day 6, 11 and 23, from root (top; early pseudotime)
to tips (bottom; late pseudotime). Each *TBX5* genotype is color-coded from light to dark, to
898   indicate time point. Note the enrichment or depletion of cells from one genotype at certain
branch points (arrowheads). Dashed lines show inferred path to CMs by *TBX5* genotype. **h**,
900   Deduced paths to non-dividing CMs of WT (black dashed line) or *TBX5^{in/del}* (blue dashed line)
are shown, from intermediate (labeled interm) to tip. **i**, Heat maps show expression for each
902   gene that displays a positive or negative correlation with pseudotime (|rho|≥0.4 and Z-score≥15
by difference in rho) in the WT path (above) and is altered in the *TBX5^{in/del}* path (below). **j**, Heat
904   maps show expression for each gene that displays a positive or negative correlation with
pseudotime (|rho|≥0.4 and Z-score≥15) in the *TBX5^{in/del}* path and is altered in the WT path

38

906 (below). **k**, Differential gene expression of inferred precursors for the cardiomyocyte branches

 (segments 69 vs. 70, dashed ovals) show several genes that display altered gene expression

908 (adj p-value<0.05 by Wilcoxon Rank Sum test) along the WT or $TBX5^{in/del}$ path. Colored blocks

 below represent the predominant $TBX5$ genotypes in each tip. **l,** Feature plots show a delayed

910 onset of expression during pseudotime for $NKX2$-5, in addition to $ATP1A1$ and $KIAA1462$.

912

914

916 **Figure 3. Subsets of cardiomyocytes respond discretely by quantitative transcriptional perturbations to reduced TBX5 dosage**. **a-c,** *TNNT2*+ clusters from day 23 were re-clustered
918 in Seurat. UMAP shows cells colored by *TBX5* genotype (**a**) or by cluster identity (**b**). **c**, Phylogenetic tree shows the relatedness of the 'average' cell per cluster among clusters. The
920 proportion of cells in each cluster are colored by *TBX5* genotype. Pairs of related clusters between *TBX5* genotypes were selected for differential gene tests. **d,** Gene ontology for
922 enriched biological processes (p-value<0.05 and q-value <0.05) in cell clusters, which are selected for differential gene expression (logfc>0.25 and adj p-value<0.05 by Wilcoxon Rank
924 Sum test), are shown. **e, g, i**, UMAPs highlight clusters used for pair-wise comparisons for differential gene tests in corresponding dot plots below. **f, h**, Dot plots of top differentially
926 expressed genes between wildtype-enriched cluster 21 and *TBX5*in/+-enriched cluster 9 (**f**), or between wildtype-enriched cluster 12 and *TBX5*in/+-enriched cluster 7 (**h**) (Supplementary Table
928 2). Each dot size corresponds to the percentage of cells expressing the gene in the cluster, and the color intensity represents scaled expression values in the cluster. Electrophysiology (EP)-
930 related (orange) and congenital heart disease (CHD)-associated (purple) genes are highlighted. Asterisks denote transcription factors. Significance was determined by Wilcoxon Rank Sum test
932 (adj p-value<0.05). **j**, The most differentially expressed genes in *TBX5*in/+-enriched clusters 0 and 6, when compared to both wildtype (WT)-enriched cluster 3 or control-enriched cluster 4,

40

934 are shown. **k**, **l,** UMAP highlights clusters for comparison (**k**) in dot plots of genes that are most differentially expressed in both *TBX5$^{in/+}$*- and *TBX5$^{in/del}$*-enriched clusters, when compared to
936 WT-enriched clusters (**l**). **m**, Heat map displays significant correlations (adj p-value<0.05 by Benjamini-Hochberg multiple corrections test) among comparisons of candidate lists for CHD-
938 associated genes, EP-related genes, genome-wide association studies (GWAS) for CHDs or arrhythmias (Supplementary Table 4), and TBX5-dependent gene sets. **n**, Circular plot shows
940 selected genes by category for WT-enriched vs. *TBX5$^{in/+}$*-enriched and WT-enriched vs. *TBX5$^{in/del}$*-enriched clusters at day 23.

942

944
Figure 4. TBX5 dosage preserves cardiomyocyte network stability. a, b, Gene regulatory networks (GRNs) for day 11 cardiomyocytes of WTC11 (**a**) or *TBX5^(in/+)* (**b**) are shown. Nodes of CHD-related (purple), heart development (red) or electrophysiology (orange) genes are shown. The size of each node represents its quantitative importance, based on pagerank centrality. Note the absence of *SMAD2* and the reduced centrality of *MEF2C* (smaller circle) in the *TBX5^(in/+)* network, compared to WTC11. **c,** Pagerank centrality for significantly altered (top 5% cutoff) nodes of CHD-associated or heart development genes at specific time points are shown. **d,** Twenty CHD-associated genes display a reduction in pagerank (top 5% cutoff) in at least one mutant *TBX5* genotype at any stage. This indicates enrichment of CHD-associated genes in TBX5 dosage-sensitive networks (p<2.2e-5 by hypergeometric test). **e,** TBX5-dependent genes with a reduction of pagerank are correlated (correlation >0.5), anti-correlated (correlation <-0.5), or indeterminate (0.5<correlation<-0.5) with *TBX5* expression in *TNNT2^+* cells. **f,** Correlations with *MEF2C* and TBX5-dependent genes with a reduction of degree in *TNNT2^+* cells are plotted. Additional data can be found in Supplementary Table 3.

964

966
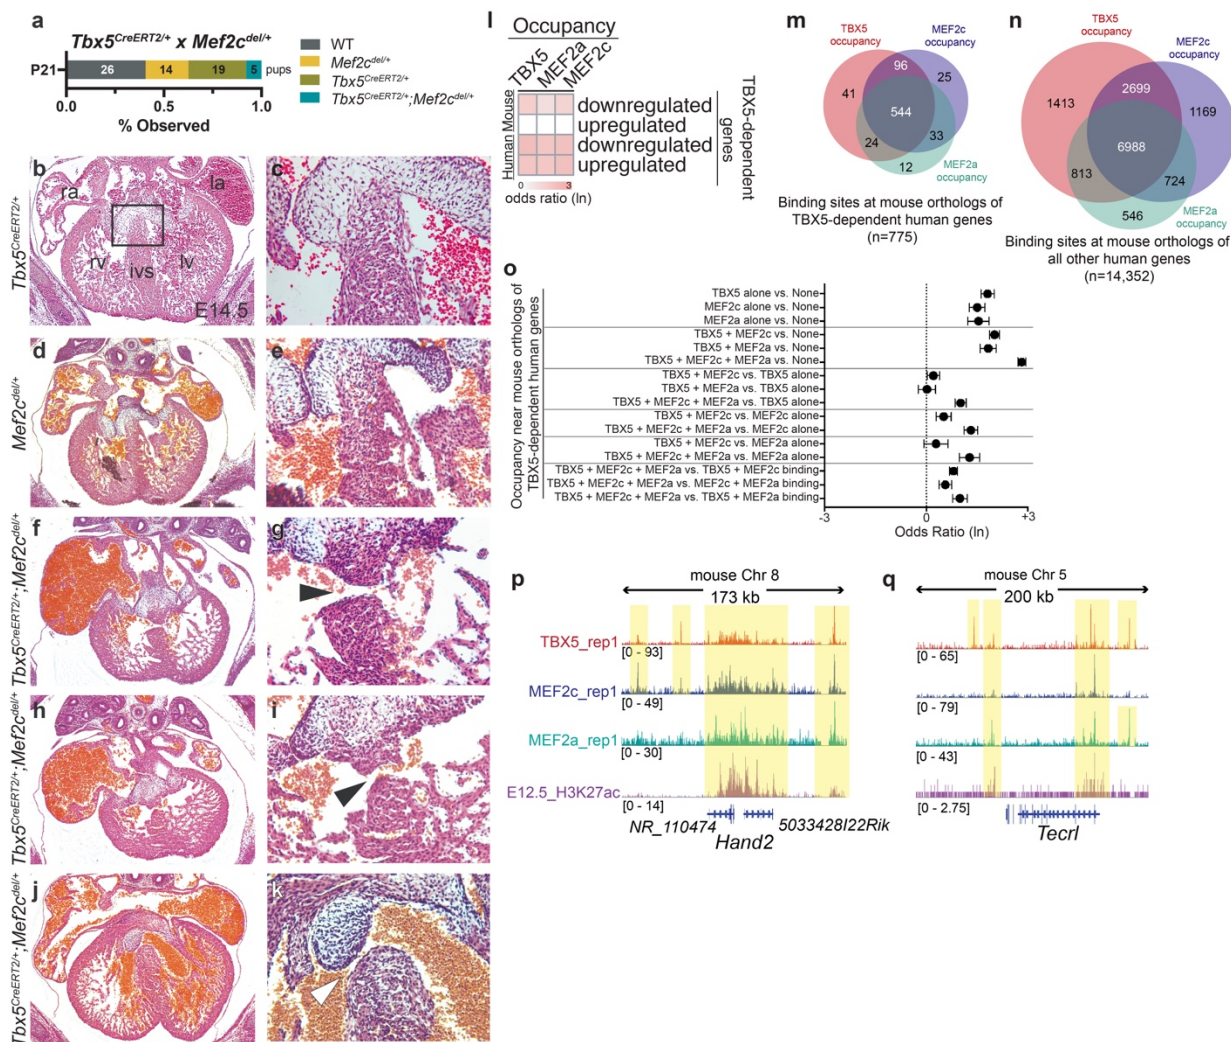

Figure 5. *Tbx5* and *Mef2c* cooperate in heart development. a, Pups at post-natal day 21 (P21) from matings of *Tbx5^{CreERT2/+}* X *Mef2c^{del/+}* were genotyped. Expected Mendelian ratios were not observed for *Tbx5^{CreERT2/+};Mef2c^{del/+}* at P21. **b, d, f, h, j**, Transverse sections of hearts at embryonic day 14.5 (E14.5) from each genotype are shown. **c, e, g, i, k**. Magnified views of the interventricular septa are shown. Note muscular VSDs (black arrowheads in **g, i**), a subaortic membranous VSD (**k**, white arrowhead) and dilated blood-filled atria in the *Mef2c^{+/-}*;*Tbx5^{CreERT2/+}* embryos (**f, h, j**). **l**, Heat map indicates odds ratios (FDR<0.05) of TBX5, MEF2a or MEF2c occupancy near mouse or human TBX5-dependent genes (Supplementary Table 6). **m, n**, Venn diagrams display the overlap of TBX5, MEF2a or MEF2c occupancy near mouse orthologs of human TBX5-dependent or -independent genes, respectively. **o,** Odds ratio (FDR<0.05) of combinations of TBX5, MEF2a or MEF2c occupancy near mouse orthologs of TBX5-dependent human genes (Supplementary Table 6). **p, q,** Browser tracks for ChIP-seq data from E12.5 hearts for TBX5, MEF2c, MEF2a and H3K27ac near conserved TBX5-dependent genes, *Hand2* (**p**) or *Tecrl* (**q**). Yellow bands of shading indicate co-occupancy.

982

984
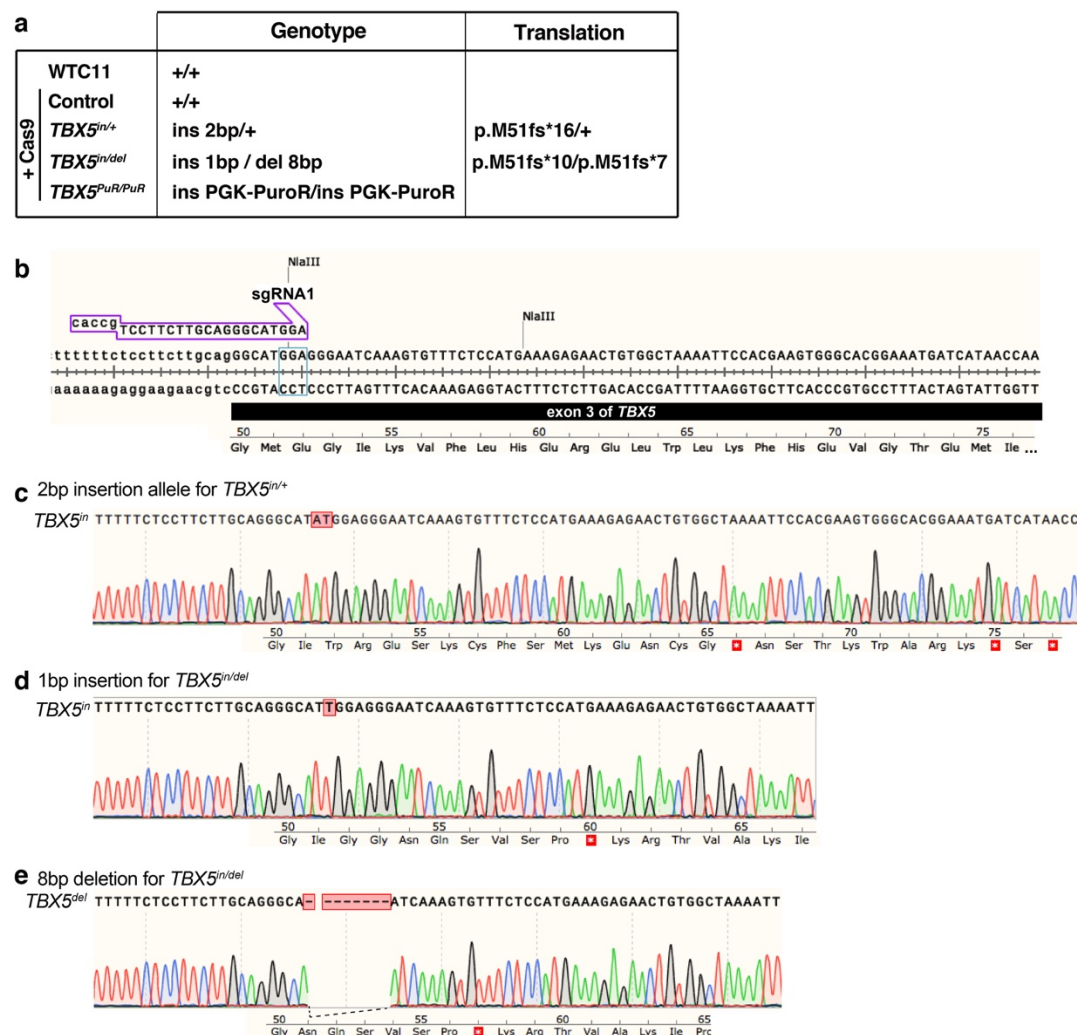

Extended Data 1. Genotype information for targeted WTC11-derived iPS cells mutant for *TBX5*. a, Table shows genotypes of WTC11-derived iPS cell lines that were targeted for *TBX5* at exon 3. Predicted translation for each *TBX5* genotype is indicated. **b**, Sequence of the exon 3 of *TBX5* is shown, along with the sgRNA1 location. The PAM site is boxed in blue. Loss of the NlaIII site at the PAM site was used in initial screening for mutant iPS cell clones by PCR. The encoded wildtype protein sequence includes the start of the T-box domain. **c**, Sequence and chromatogram for the 2bp insertion of the mutant allele for *TBX5^{in/+}* predicts a premature truncation, as indicated by a stop codon (white asterisk in red box) in the frame-shifted protein sequence. **d**, **e**, Sequence and chromatogram for the 1 bp insertion, or 8 bp deletion, respectively, of the mutant allele for *TBX5^{in/del}*, along with corresponding protein sequences, are shown.

44
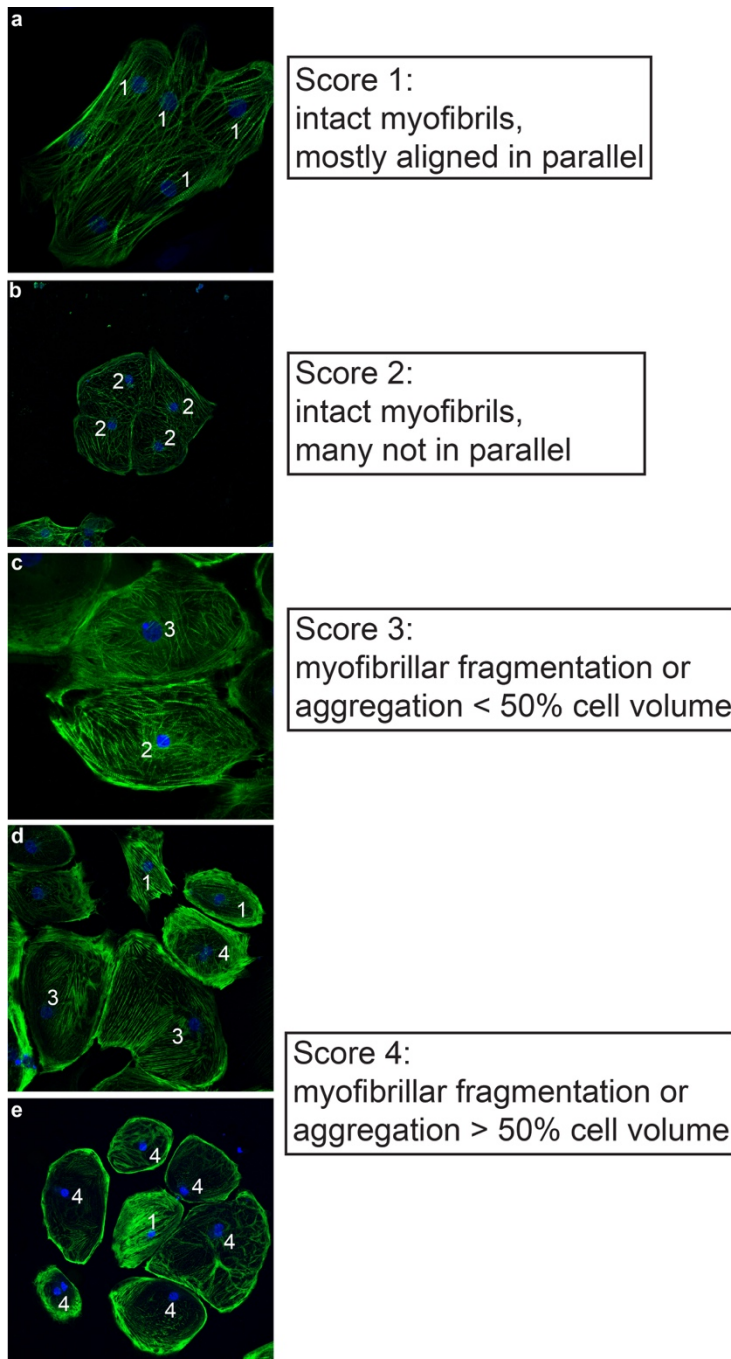

998 **Extended Data 2. Scoring criteria for myofibrillary disarray.** Criteria for scores 1-5 are
indicated, and representative images for each score are shown.
1000

1002

1004

46
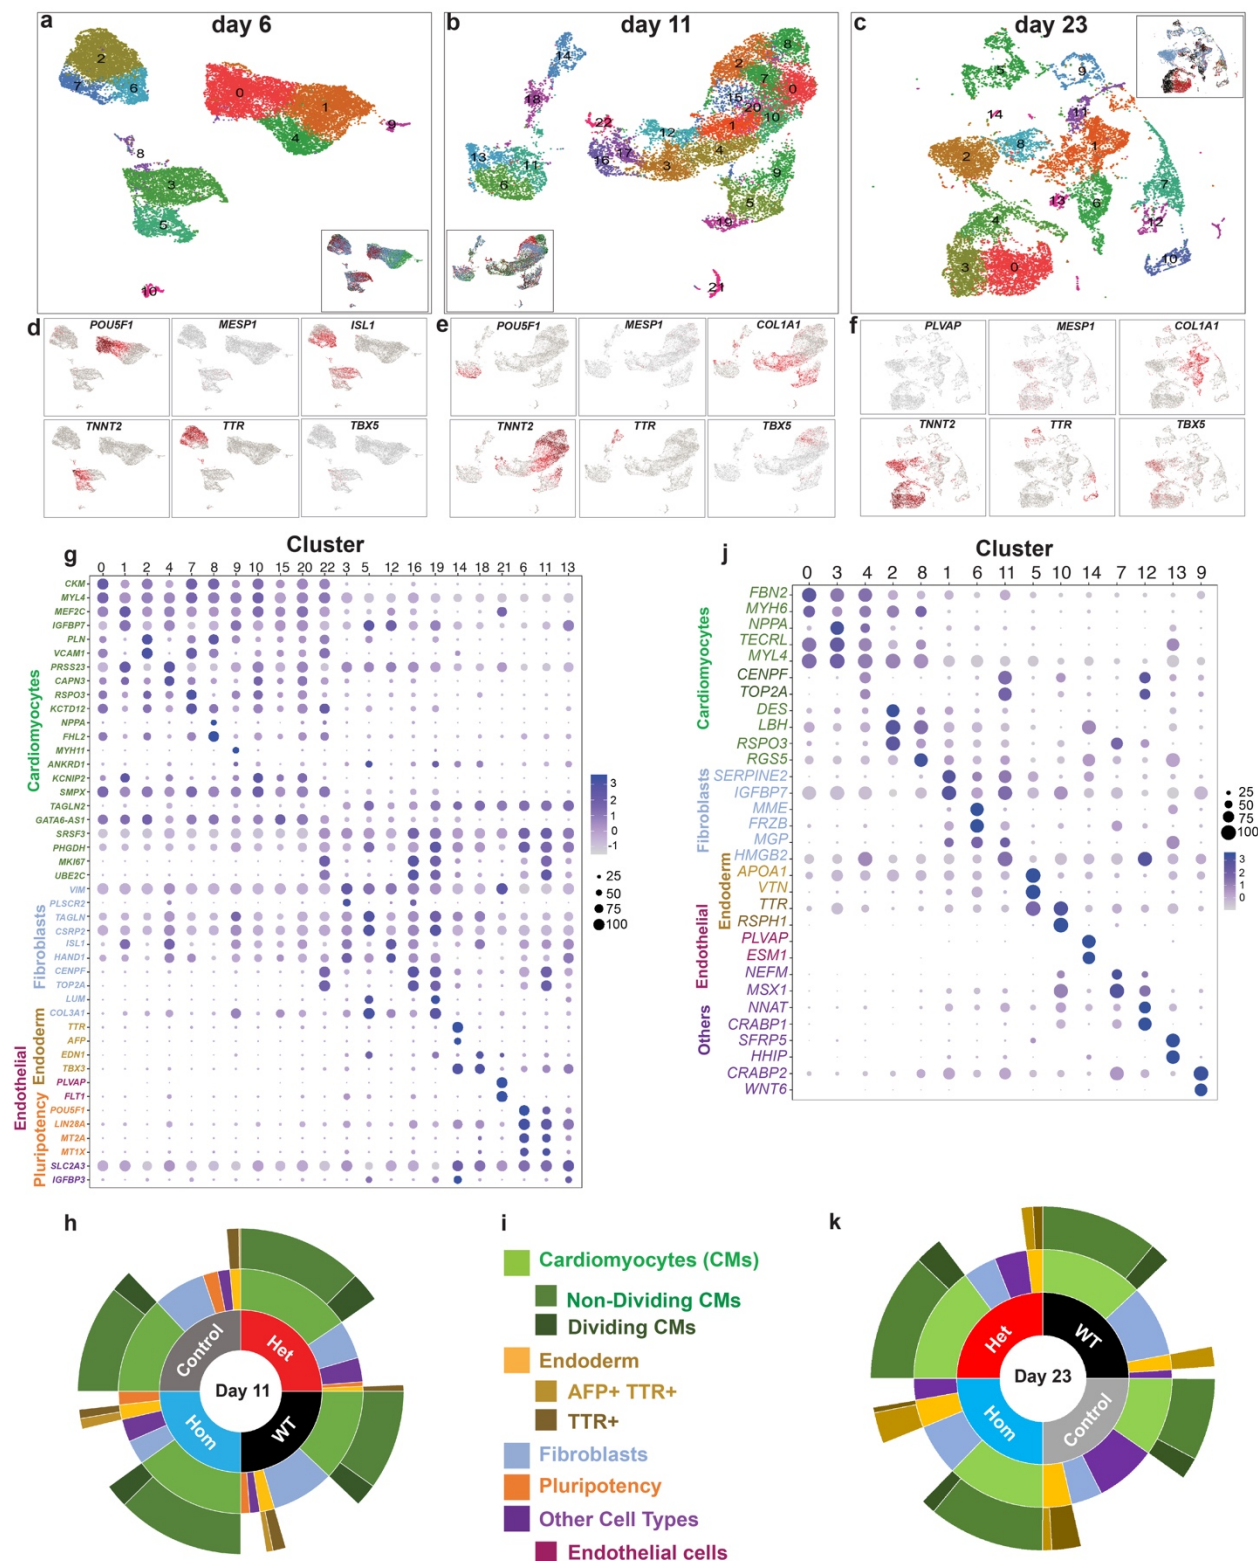

1006   **Extended Data 3. Human cardiac differentiation is sensitive to reduced TBX5 dosage. a-c**, UMAPs display cells at day 6, day 11 and day 23, respectively, by Louvain clustering. Insets
1008   show UMAPs colored by *TBX5* genotype. **d-f**, Feature plots in UMAP space demonstrate expression of selected marker genes, which represent major cell types at each timepoint. **g, j**,
1010   Dot plots display two of the top marker genes that are expressed in each cluster at day 11 or day 23 (adj p-value<0.05 by Wilcoxon Rank Sum test), and define at least five major human cell
1012   types. The size of the dot corresponds to the percentage of cells expressing the gene in the cluster, and the color intensity represents the level of gene expression in the cluster. **h, i, k**,
1014   Sunburst plots indicate the proportion of at least five major cell types, based on top marker genes, by *TBX5* genotype at day 11 or day 23.
1016

47
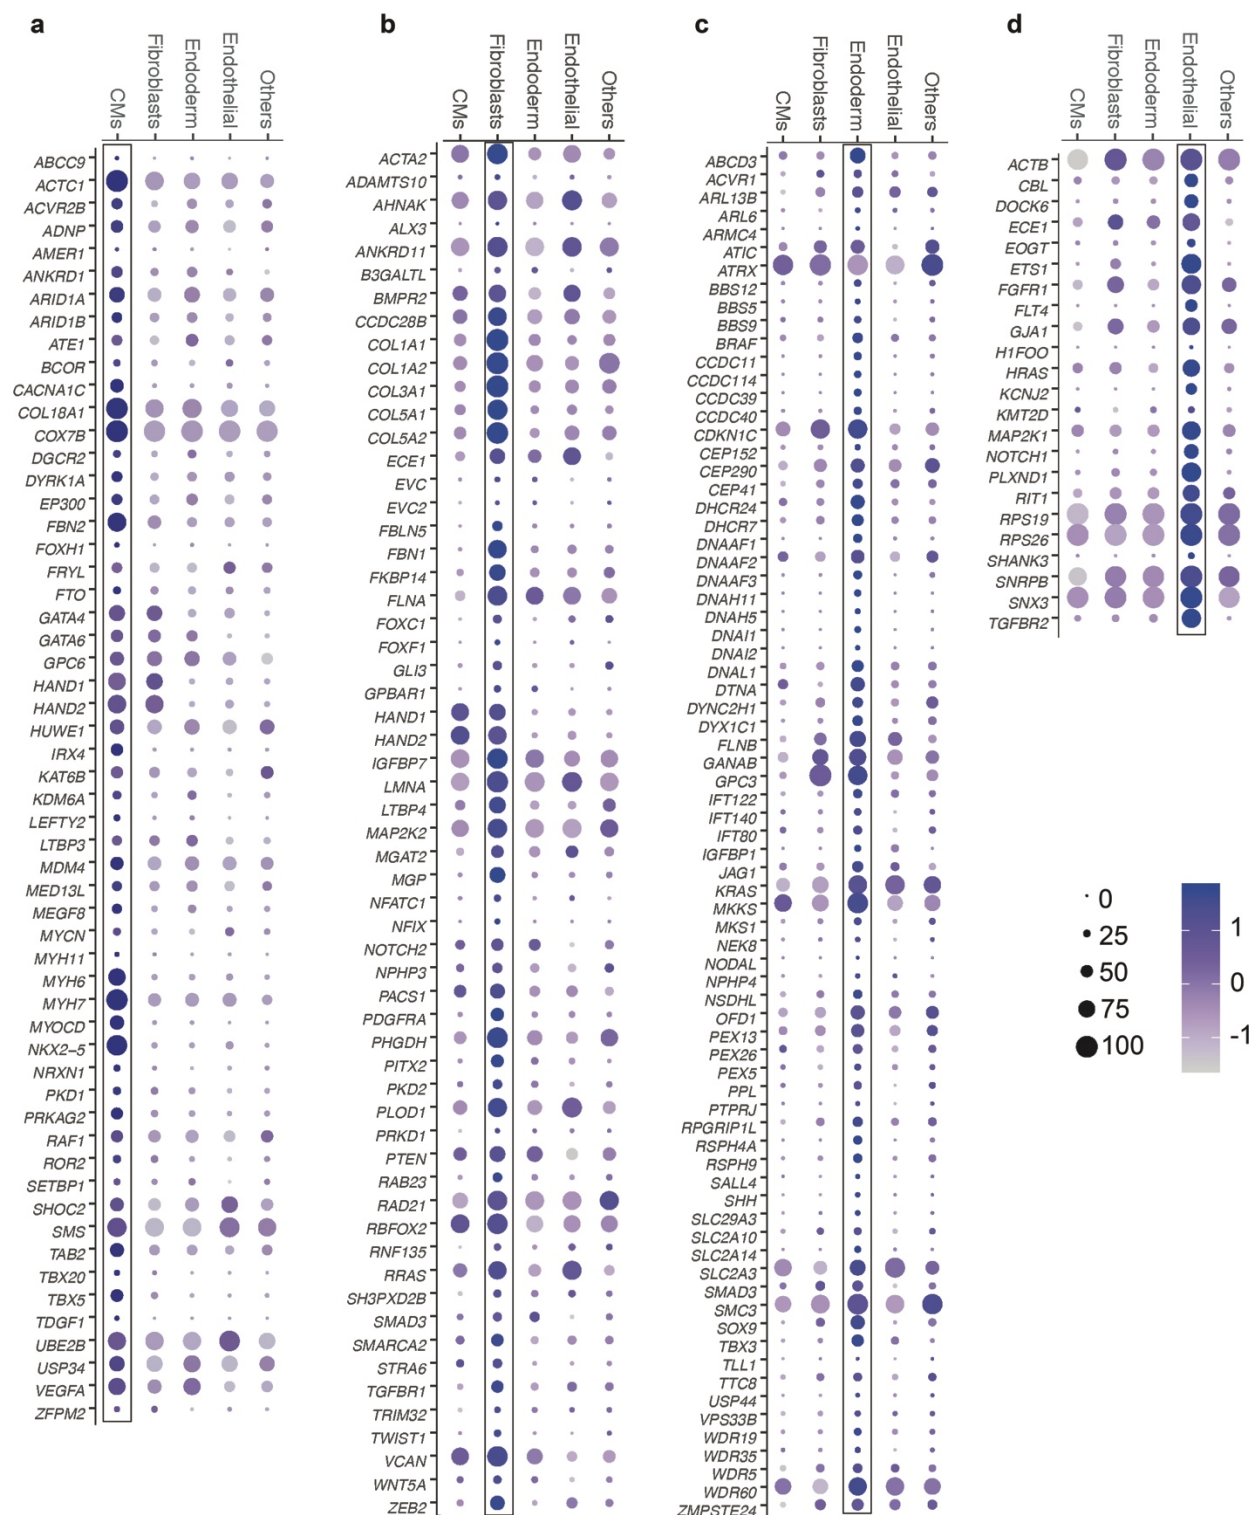

Extended Data 4. Many CHD-associated genes are enriched among several human cell types. a-d, Dot plots show the expression of congenital heart disease (CHD)-associated genes that are significantly enriched in cardiomyocytes (**a**), fibroblasts (**b**), endodermal cells (**c**) or

1024   endothelial cells (**d**). Significance was determined by Wilcoxon Rank Sum test (adj p-value<0.05).

1026

1028
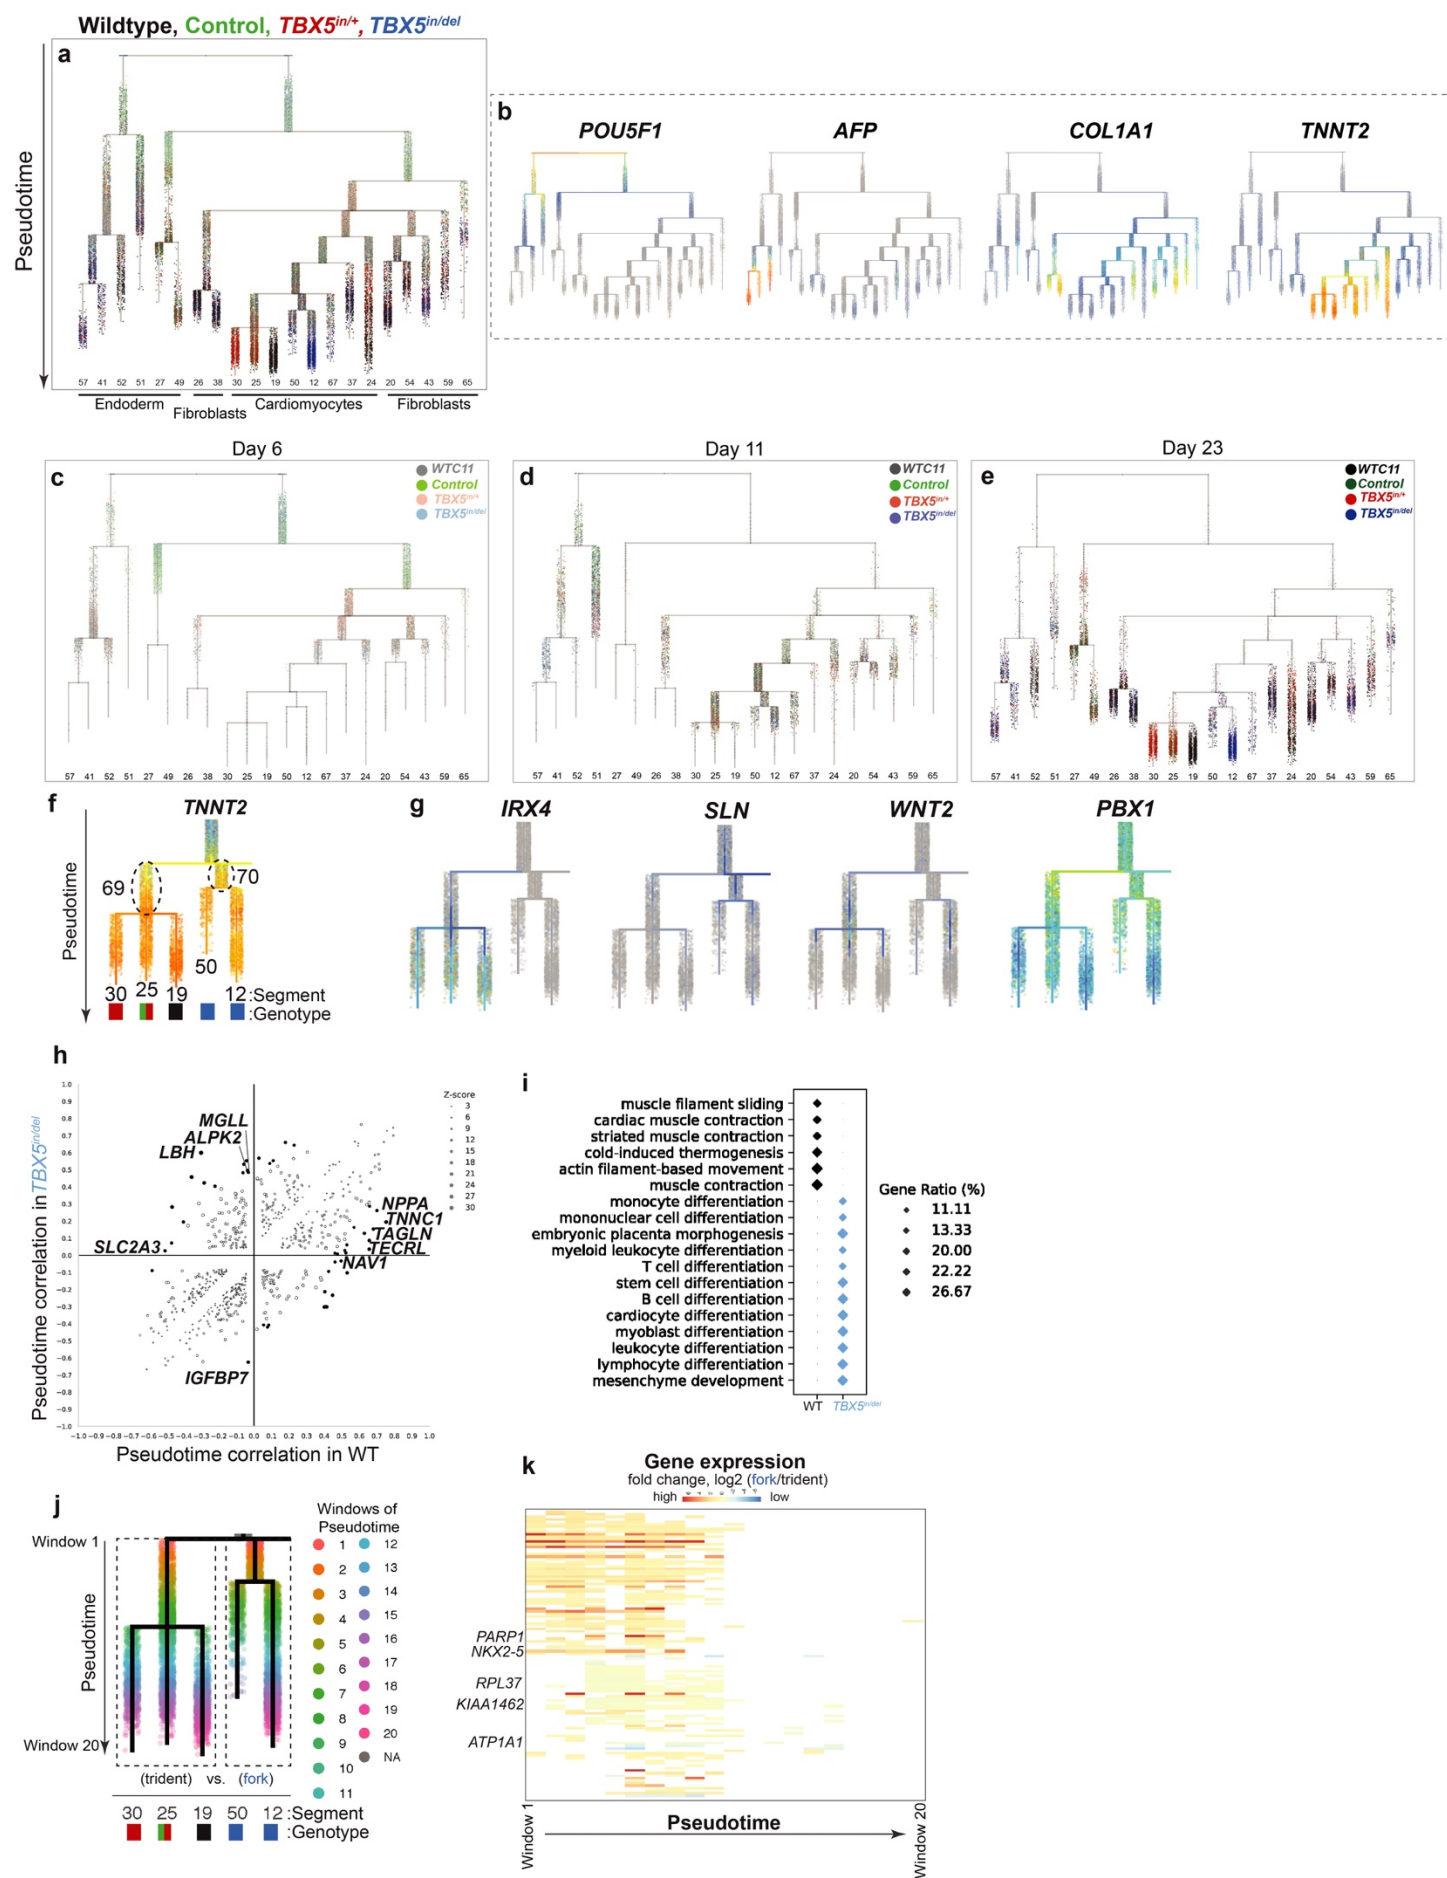

Extended Data 5. Pseudotime analysis of cell trajectory reconstructions by genotype,
1030   **time point and cell type. a,** All cells for all *TBX5* genotypes and time points are shown for directed differentiation to cardiomyocytes in a single plot. Pseudotime is displayed from root
1032   (top) to tips (bottom). **b,** Genes, which mark each major cell type (pluripotent cell, endoderm, fibroblast and cardiomyocyte) during the directed differentiation, are shown. **c-e**, Cells from all
1034   *TBX5* genotypes are shown by time point. **f,** Differential gene expression between inferred precursors (dashed ovals, segments 69 vs. 70) of the WT or *TBX5$^{in/del}$* path was evaluated. **g,**
1036   Delayed activation of *WNT2, PBX1* and *NKX2-5* in the *TBX5$^{in/del}$* path (to segments 50 and 12) diverged from the path of other genotypes (to segments 20, 25, 19). *IRX4* was absent in the
1038   *TBX5$^{in/del}$* path, and instead, *SLN* was enriched. Significance was determined by Wilcoxon Rank Sum test (adj p-value<0.05). **h**, Scatter plot displays two axes of Spearman rho correlations,
1040   which measure a potential relationship between gene expression and pseudotime for WT or *TBX5$^{in/del}$* cell. Each white circle represents a gene that has a significant rho correlation with
1042   pseudotime (p-value<0.05 by two-sided *t* test). Size of the circle represents a Z-score difference for rho correlation of a gene to pseudotime for WT versus *TBX5$^{in/del}$* path. As the size of the
1044   circle increases, there is a larger difference in how a gene is correlated with pseudotime between the two genotypes. Black circles represent genes with a moderate correlation or better
1046   with pseudotime in either path (|rho|≥0.4) and (Z-score≥15), when the opposing genotype has no significant correlation to pseudotime (p-value≥0.05 by two-sided *t* test). **i,** Gene ontology
1048   (GO) terms for enriched biological processes (p-value<0.05 and q-value<0.05), which are based on genes that positively correlate with pseudotime (|rho|≥0.4 and Z-score≥15 by difference in
1050   rho) in the WT- or the *TBX5$^{in/del}$* path, are shown. Black (WT) or blue (*TBX5$^{in/del}$*) diamonds show gene ratios. **j,** Deduced paths for WT/control/ *TBX5$^{in/+}$* (trident) or *TBX5$^{in/del}$* (fork) to
1052   cardiomyocytes were divided into windows (1-20) along pseudotime for comparison. **k**, Heat map shows fold change for genes in a cluster that includes *NKX2-5,* which was significantly
1054   different after correction (adj p-value<0.05 by Bonferroni-Holm test) in windows 2 through 8, along with genes of a similar pattern, including *PARP1, RPL37, KIAA1462,* and *ATP1A1* (adj p-
1056   value<0.05 by Bonferroni-Holm test).

51
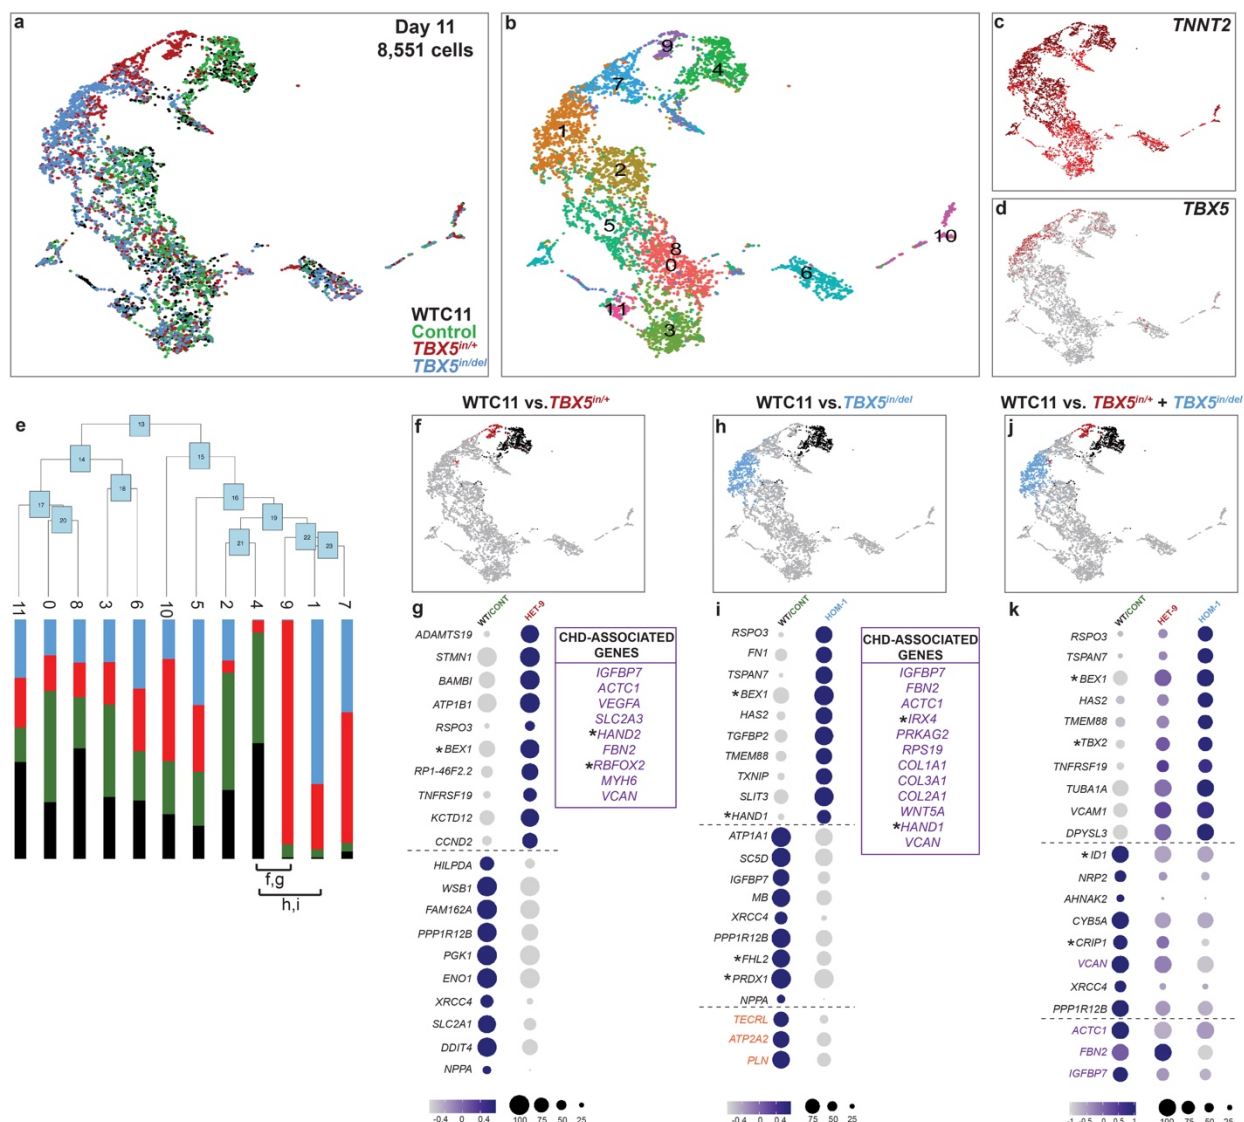

Extended Data 6. Evaluation of reduced TBX5 dosage by gene expression in cardiomyocytes at day 11. **a, b**, UMAPs of $TNNT2^+$ cells from day 11 of differentiation are colored by $TBX5$ genotype or by cluster identity, respectively. **c, d**, Feature plots by UMAP display expression of $TNNT2$ or $TBX5$. **e,** Phylogenetic tree depicts cluster relatedness. Vertical bars show the proportion of cells by color of each $TBX5$ genotype. **f, h,** UMAPs highlight clusters chosen for pair-wise differential gene expression comparisons. **g, i**, Dot plots show top differentially expressed genes between WT/control-enriched and $TBX5^{in/+}$-enriched clusters, or WT/control-enriched and $TBX5^{in/del}$-enriched clusters, respectively. Electrophysiology-related (orange) and congenital heart disease (CHD)-associated (purple) genes are highlighted. Significance was determined by Wilcoxon Rank Sum test (adj p-value<0.05). **j,** UMAP demonstrates pair-wise comparisons between WT/control-enriched and $TBX5^{in/+}$-enriched clusters, and WT/control-enriched and $TBX5^{in/+}$-enriched clusters. **k**, Common genes that are differentially expressed in both $TBX5^{in/+}$ and $TBX5^{in/del}$, in each comparison with WT/control are shown.

52
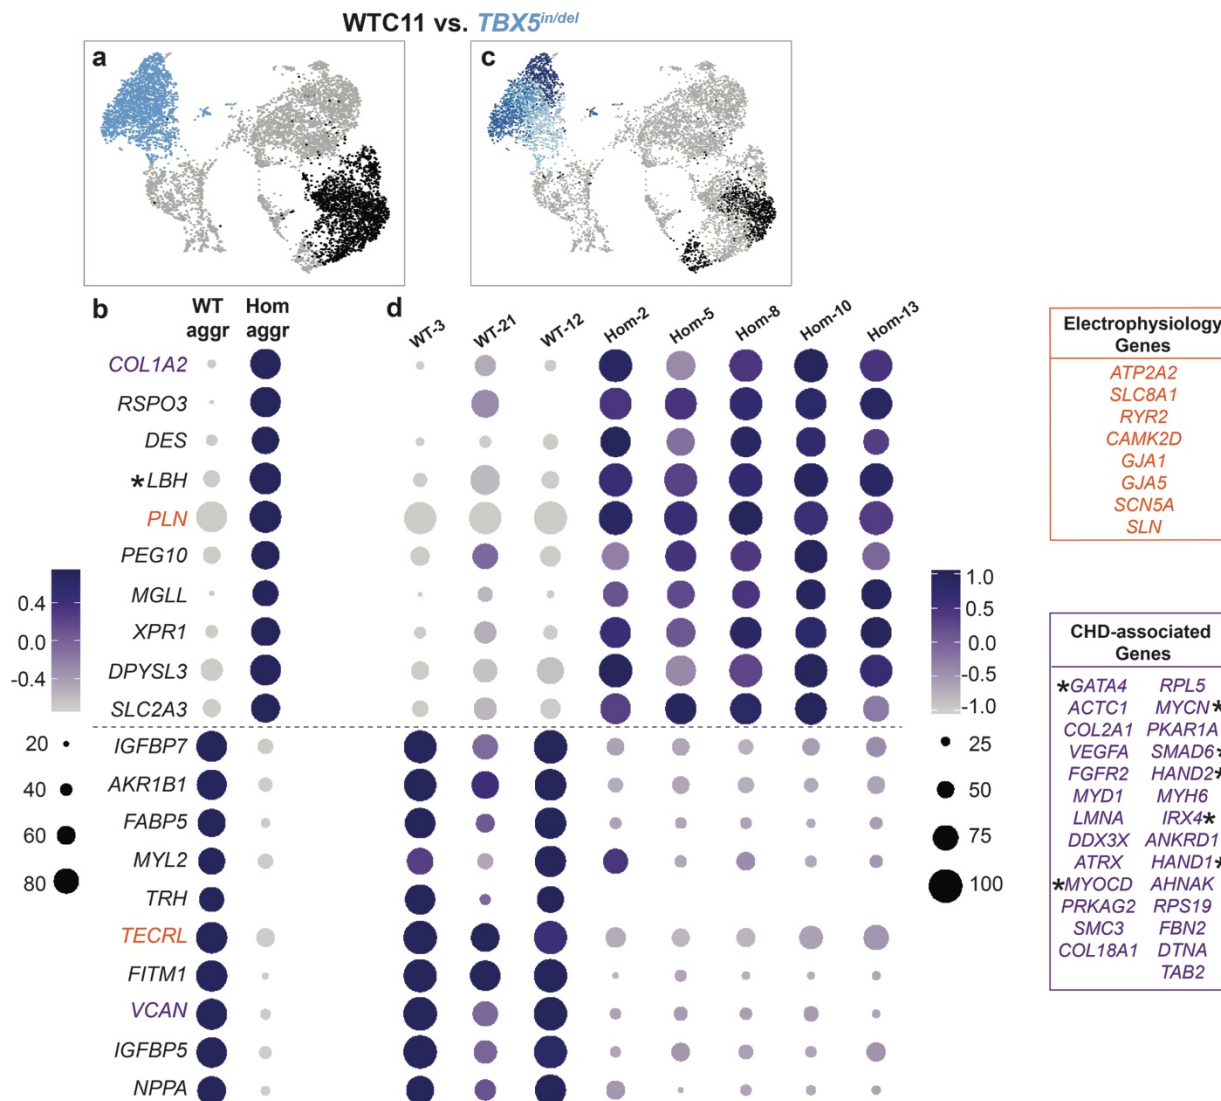

Extended Data 7. Loss of *TBX5* by gene expression in individual cardiomyocytes at day 23. a, UMAP of day 23 cardiomyocytes displays a wildtype-enriched (black) and *TBX5^{in/del}*-enriched (blue) cluster, at a low Louvain resolution in Seurat, for comparison between clusters of *TBX5* genotypes. **b**, Dot plots showing top differentially expressed genes between aggregate WT-enriched and *TBX5^{in/del}*-enriched clusters. Transcriptional regulators are denoted by asterisks. Electrophysiology-related (orange) and congenital heart disease (CHD)-associated (purple) are highlighted. Significance was determined by Wilcoxon Rank Sum test (adj p-value<0.05). **c**, UMAP shows clusters at a higher resolution, with three wildtype-enriched (black) sub-clusters and five *TBX5^{in/del}*-enriched (shades of blue) sub-clusters. **d,** Heterogeneity of gene expression among labeled sub-clusters are shown.

1090
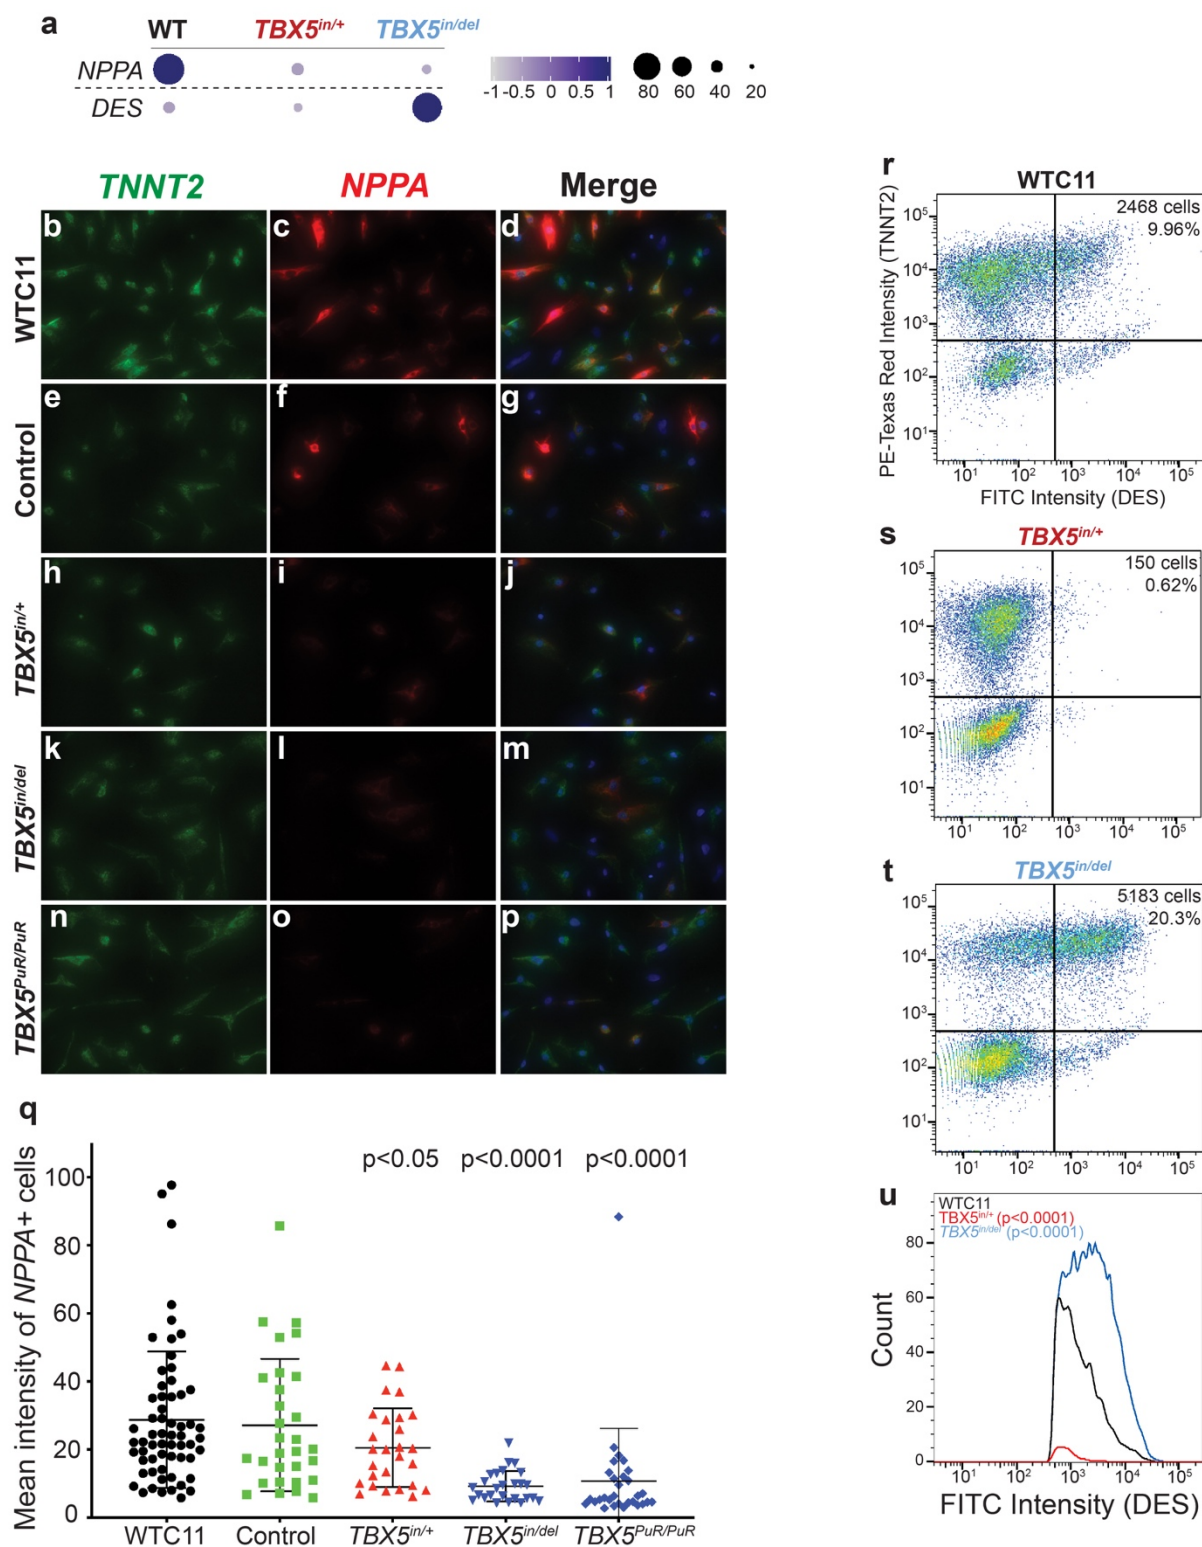

Extended Data 8. Single cell analysis of TBX5-dependent genes by orthogonal assays. a, Dot plots show expression of *NPPA* and *DES* in WTC11 (WT)-, *TBX5^in/+*- and *TBX5^in/del*-enriched clusters at day 23. **b-p,** Fluorescence *in situ* hybridization is visualized for *TNNT2*

54

1096 (green) or *NPPA* (red) in day 23 cardiomyocytes, from (**b-d**) WTC11, (**e-g**) control, (**h-j**) *TBX5*$^{in/+}$, (**k-m**) *TBX5*$^{in/del}$ and (**n-p**) *TBX5*$^{PuR/PuR}$ cells. **q,** Graph displays mean intensity of *NPPA* signal of individual double-positive *TNNT2*$^{+}$/*NPPA*$^{+}$ cells by *TBX5* genotype. Significance of p-

1098 values were calculated by unpaired *t* test. **r-t,** Pseudocolor plots showing cTNT^{+} and DES^{+} double positive cells in (**r**) wildtype, (**s**) *TBX5*$^{in/+}$ or (**t**) *TBX5*$^{in/del}$ at day 23. **u,** Histogram of FITC

1100 intensity of DES^{+} cells from wildtype, *TBX5*$^{in/+}$ or *TBX5*$^{in/del}$ cells is shown (****p-value<1E-4 by Chi-Square test).

1102

55

1104

56
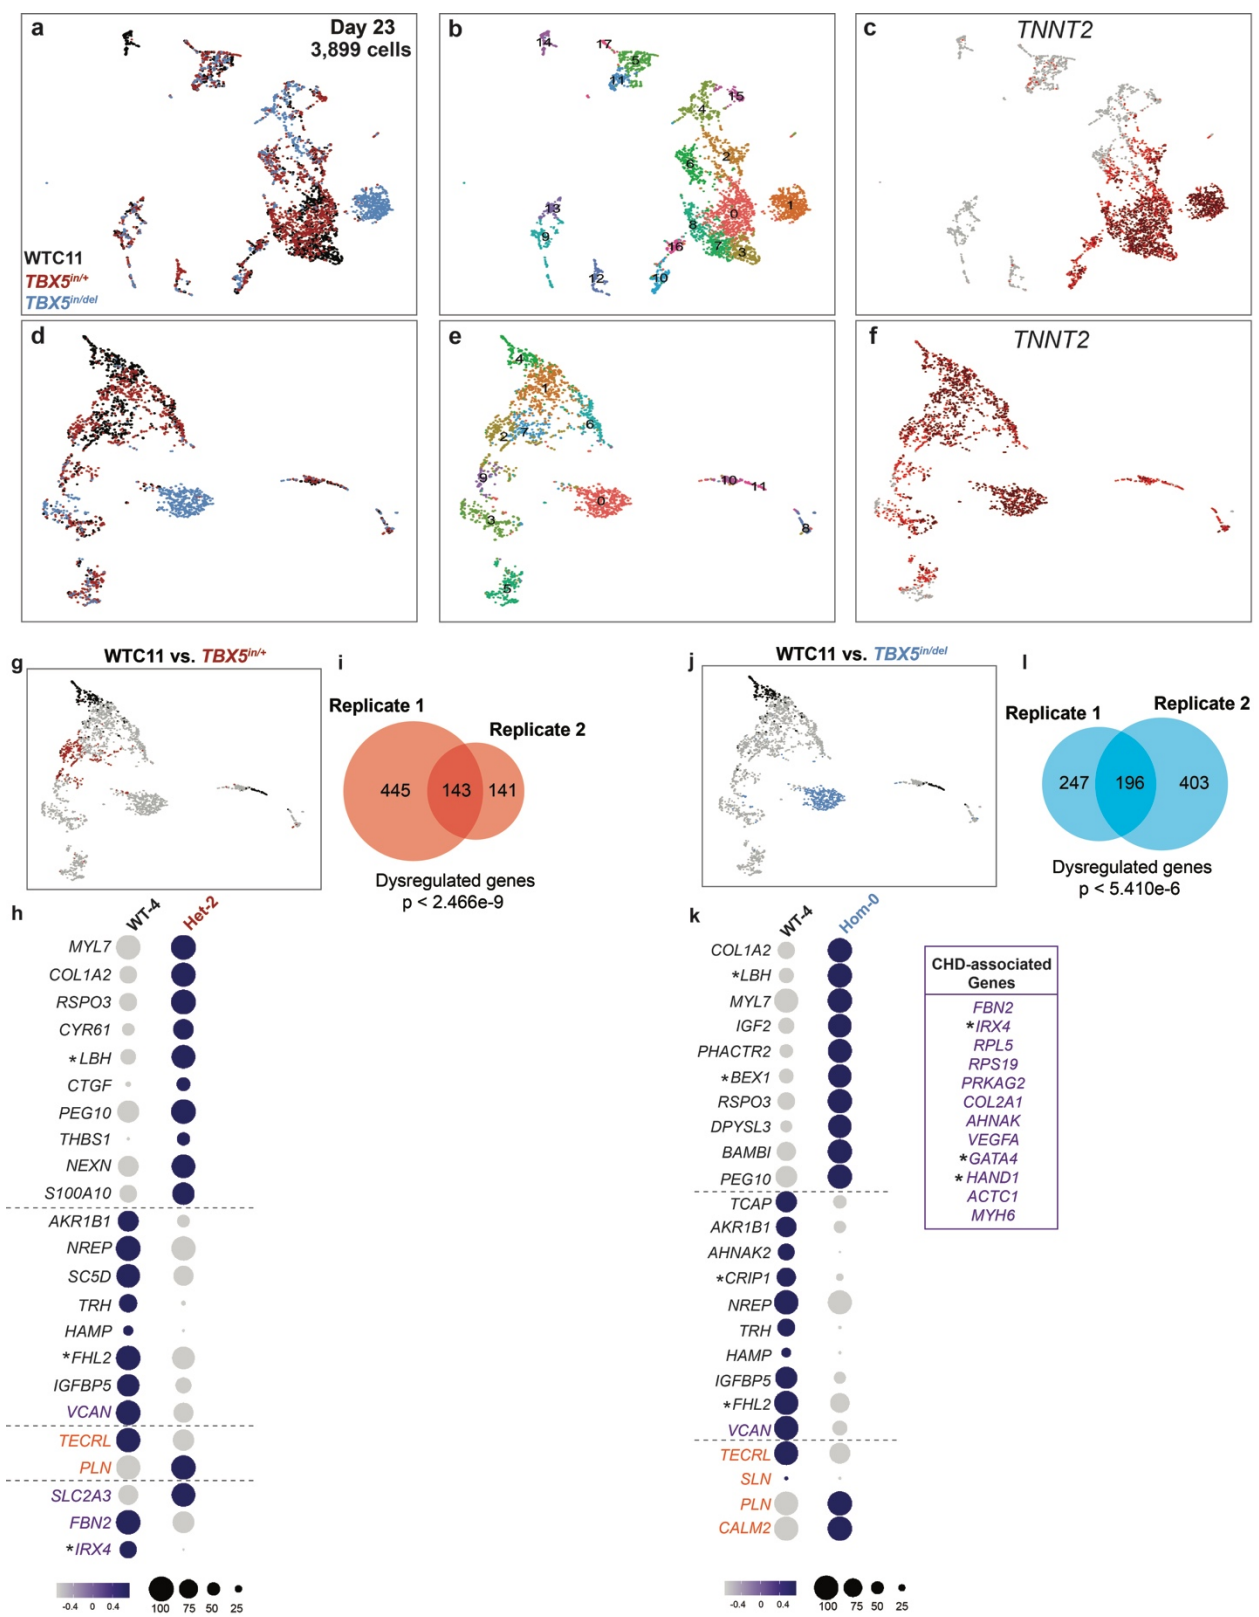

1106 **Extended Data 9. Biological replicate of TBX5 dose-sensitive responses in WTC11-derived cardiomyocytes at day 23. a, b,** Cells at day 23 of an independent differentiation
1108 (biological replicate) were collected for single cell RNAseq analysis. UMAP shows all cells from day 23 colored by *TBX5* genotype or by cluster identity, respectively. **c,** UMAP shows *TNNT2*
1110 expression. **d, e,** UMAP of *TNNT2*⁺ cells from day 23 are colored by *TBX5* genotype or by cluster identity, respectively. **f,** UMAP shows *TNNT2* expression in *TNNT2*⁺ cells. **g, j,** UMAPs
1112 highlight clusters used in pair-wise differential gene tests. **h, k,** Dot plots show top differentially expressed genes between wildtype (WT)-enriched and *TBX5*$^{in/+}$-enriched or *TBX5*$^{in/del}$-enriched
1114 clusters (Supplementary Table 2). Electrophysiology-related (orange) or congenital heart disease (CHD)-associated (purple) genes are indicated. Asterisks denote transcription factors.
1116 Significance was determined by Wilcoxon Rank Sum test (adj p-value<0.05). **i, l,** Venn diagrams show overlap of differentially expressed genes detected in the first and second
1118 biological replicates at day 23. Statistical significance was determined by Hypergeometric test, based on the union of highly variable genes from both datasets (1,688) as the population size.
1120

1122
Extended Data 10. Overlap of TBX5 dose-dependent genes between biological replicates.

1124 **a,** Venn diagram shows overlap of differentially expressed genes detected at day 23 in WTC11-targeted $TBX5^{in/+}$ and $TBX5^{in/del}$ cells from biological replicate 1 and replicate 2. Statistical

1126 significance was determined by Hypergeometric test, based on the union of highly variable genes from both datasets (1,688) as the population size. **b, d,** UMAPs demonstrate clusters

1128 chosen for differential gene expression within each experiment for comparison. **c, e,** Dot plots show top differentially expressed genes for replicates. Significance was determined by Wilcoxon

1130 Rank Sum test (adj p-value<0.05). **f,** Venn diagram shows overlap of differentially expressed genes between genetic backgrounds of WTC11-targeted $TBX5^{in/+}$ and $TBX5^{in/del}$ cells and PGP1-

1132 targeted $TBX5^{in/+}$ and $TBX5^{del/del}$ cells. **g, i,** UMAPs show clusters chosen for differential gene expression for comparison. **h, j,** Dot plots show top differentially expressed genes in each

1134 genetic background by $TBX5$ genotype.
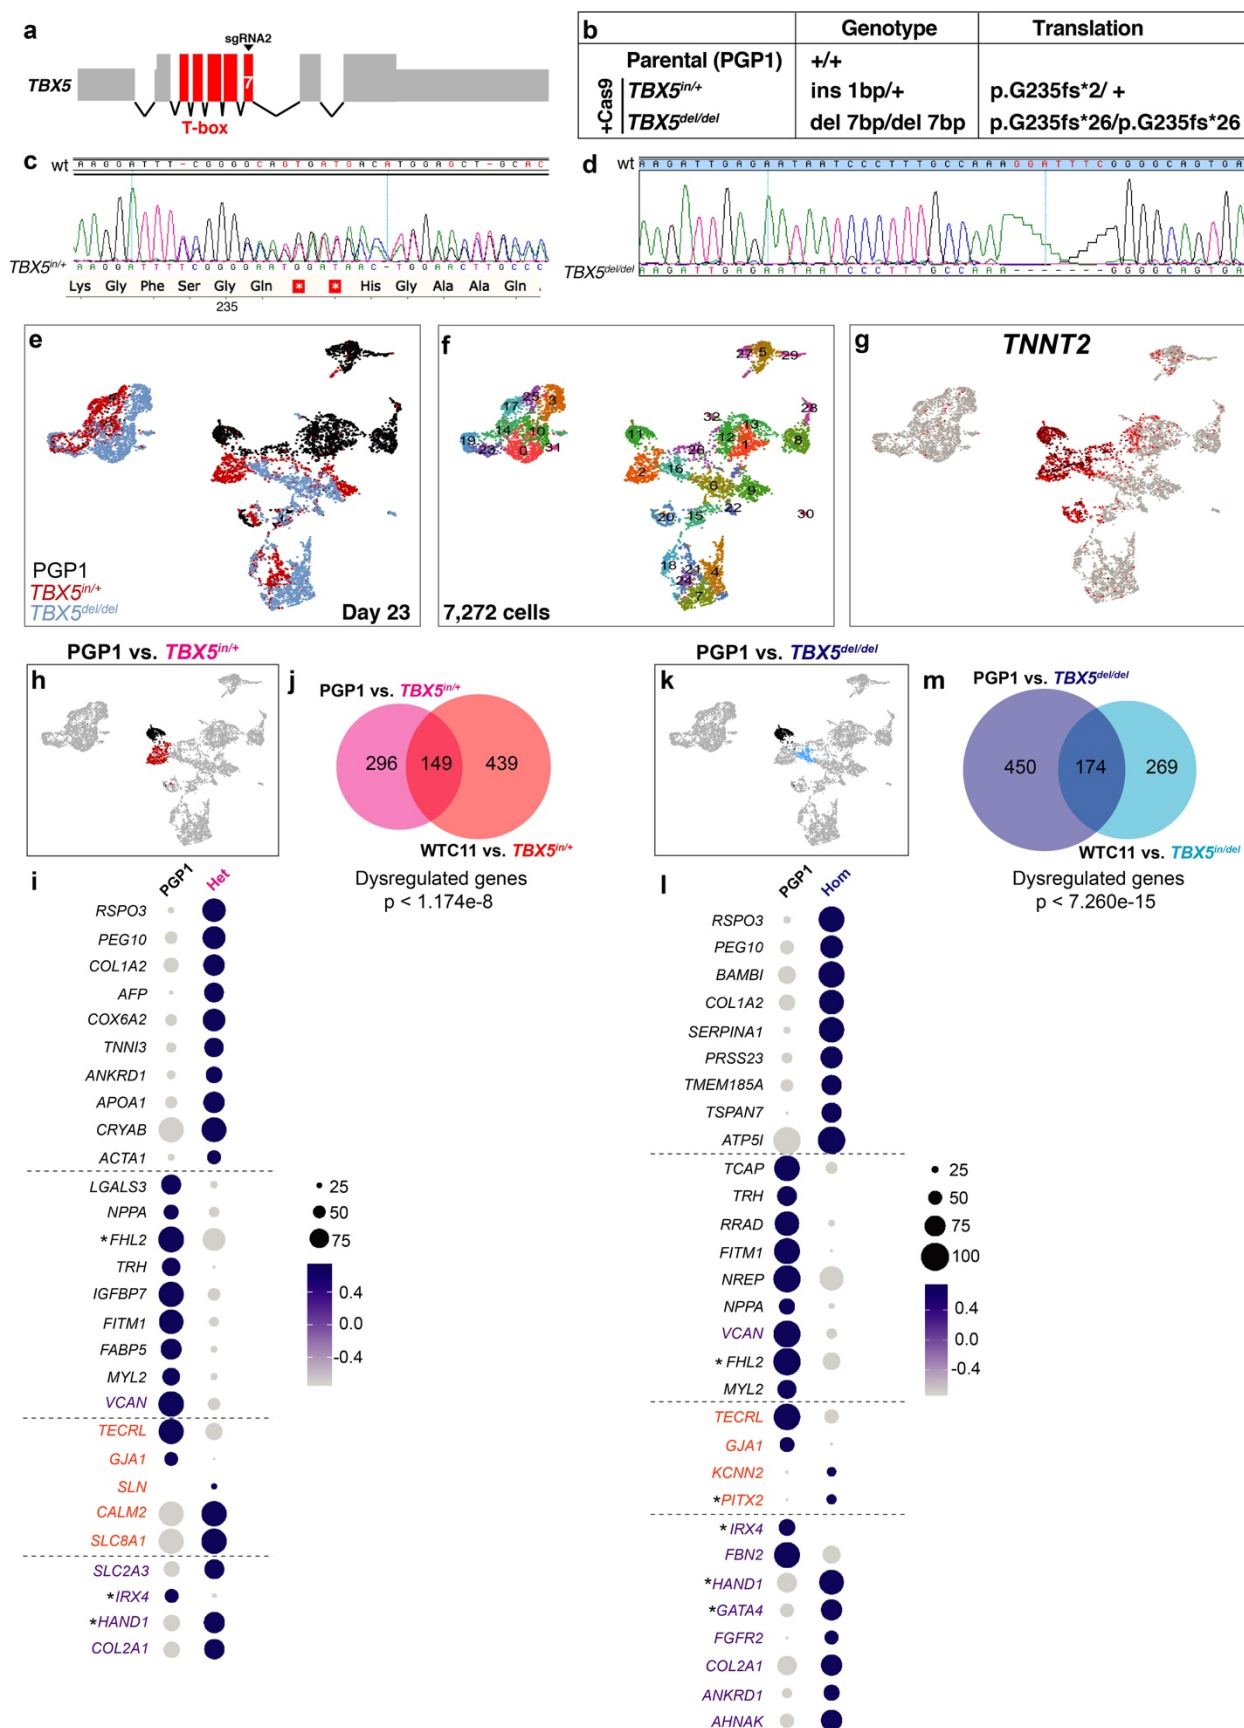

1138   **Extended Data 11. Assessment of an alternative genetic background for TBX5 dose-sensitive gene expression. a,** Diagram of human *TBX5* gene is shown, with exons in red. The

1140   guide sgRNA2 was used to target exon 7, which encodes a portion of the T-box domain, of *TBX5* in PGP1 iPS cells. **b,** Table specifies the nature of each *TBX5* mutation and the predicted

1142   translation of TBX5 for PGP1-derived *TBX5$^{in/+}$* or *TBX5$^{del/del}$* cells. **c, d,** Chromatogram indicates a 1 base pair insertion of the mutant *TBX5* allele for PGP1-derived *TBX5$^{in/+}$* cells (**c**) or a 7 base

1144   pair deletion of *TBX5* in *TBX5$^{del/del}$* cells (**d**). **e-g,** UMAPs of all cells from day 23 by *TBX5* genotype (**e**), cluster identity (**f**), or by *TNNT2* expression (**g**). **h, k,** UMAPs mark *TBX5*

1146   genotype-enriched clusters by color that were selected for differential gene expression test. **i, l,** Dot plots show top differentially expressed genes in (**i**) *TBX5$^{in/+}$*- or (**l**) *TBX5$^{del/del}$*-enriched

1148   clusters. Significance was determined by Wilcoxon Rank Sum test (adj p-value<0.05) (Supplementary Table 2). **j,** Venn diagram shows overlap of TBX5-dependent gene sets

1150   between differences of WTC11 and WTC11-derived *TBX5$^{in/+}$* clusters and differences of PGP1 and PGP1-derived *TBX5$^{in/+}$* clusters. **m,** Venn diagram displays overlap of TBX5-dependent

1152   gene sets between differences of WTC11 and WTC11-derived *TBX5$^{in/del}$* and differences of PGP1 and PGP1-derived *TBX5$^{del/del}$*. Statistical significance was determined by Hypergeometric

1154   test, based on the union of highly variable genes from both datasets (2,566) as the population size.

1160 **Extended Data 12. Overlap of TBX5 dose-dependent genes between genetic backgrounds. a,** Venn diagram shows overlap of differentially expressed genes between

1162 genetic backgrounds of WTC11-targeted $TBX5^{in/+}$ and $TBX5^{in/del}$ cells and PGP1-targeted $TBX5^{in/+}$ and $TBX5^{del/del}$ cells. Statistical significance was determined by Hypergeometric test,

1164 based on the union of highly variable genes from both datasets (2,566) as the population size. **b, d,** UMAPs show clusters chosen for differential gene expression for comparison. **c, e,** Dot

1166 plots show top differentially expressed genes in each genetic background by $TBX5$ genotype (adj p-value<0.05 by Wilcoxon Rank Sum test).

1168

a
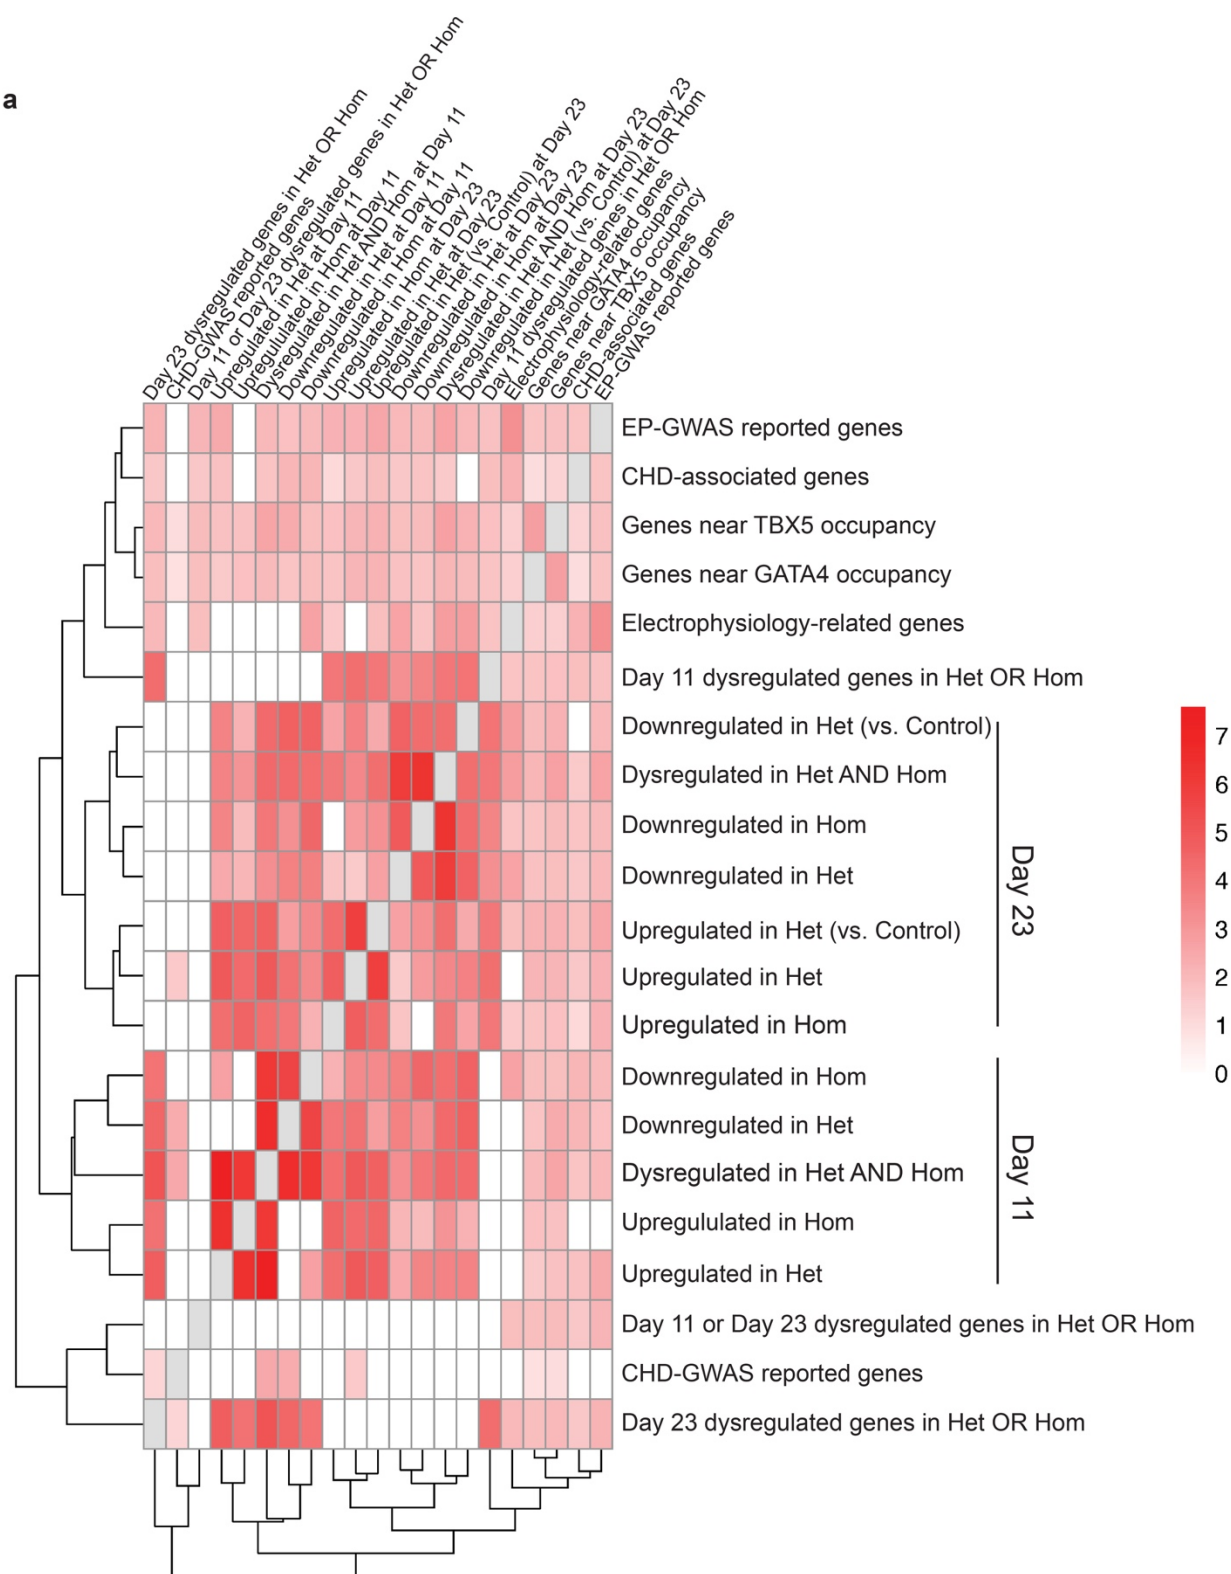

1170

1172

1174   **Extended Data 13. Associations between disease candidates, GWAS reported genes, TBX5 or GATA4 occupancy, or TBX5-dependent genes. a,** Heat map indicates odds ratios

1176   (FDR<0.05) between several variables, including CHD-associated genes, EP-related genes, CHD-related GWAS reported genes, arrhythmia-related GWAS (EP-GWAS) reported genes,

1178   TBX5 or GATA4 occupancy, and TBX5-dependent gene sets at day 11 or day 23 (Supplementary Table 4). Statistical significance was determined by Benjamini-Hochberg

1180   multiple testing.

1182
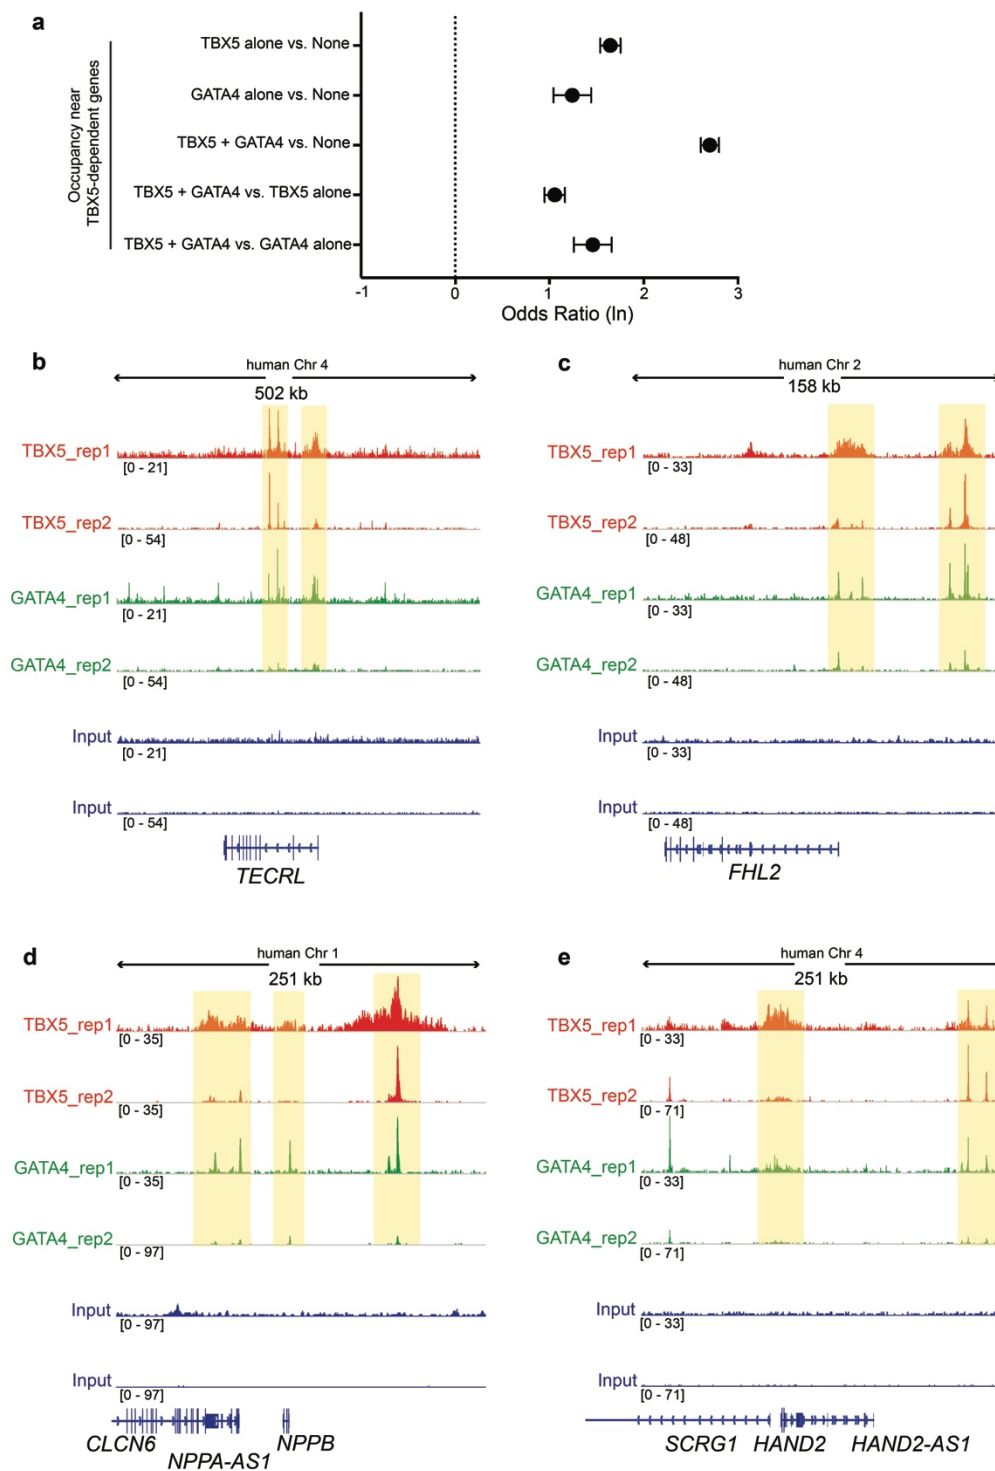

Extended Data 14. Co-occupancy of TBX5 or GATA4 near human TBX5-dependent genes.

1184   **a,** Odds ratios (FDR<0.05) of TBX5, GATA4 or TBX5 and GATA4 occupancy near all human TBX5-dependent genes. Statistical significance was determined by Benjamini-Hochberg

1186   multiple testing (Supplementary Table 5). **b,** Browser tracks of TBX5 and GATA4 occupancy from iPS cell-derived cardiomyocytes are shown for loci of TBX5-dependent genes *TECRL,*

1188   *FHL2, NPPA/NPPB* or *HAND2.*

1190

1192
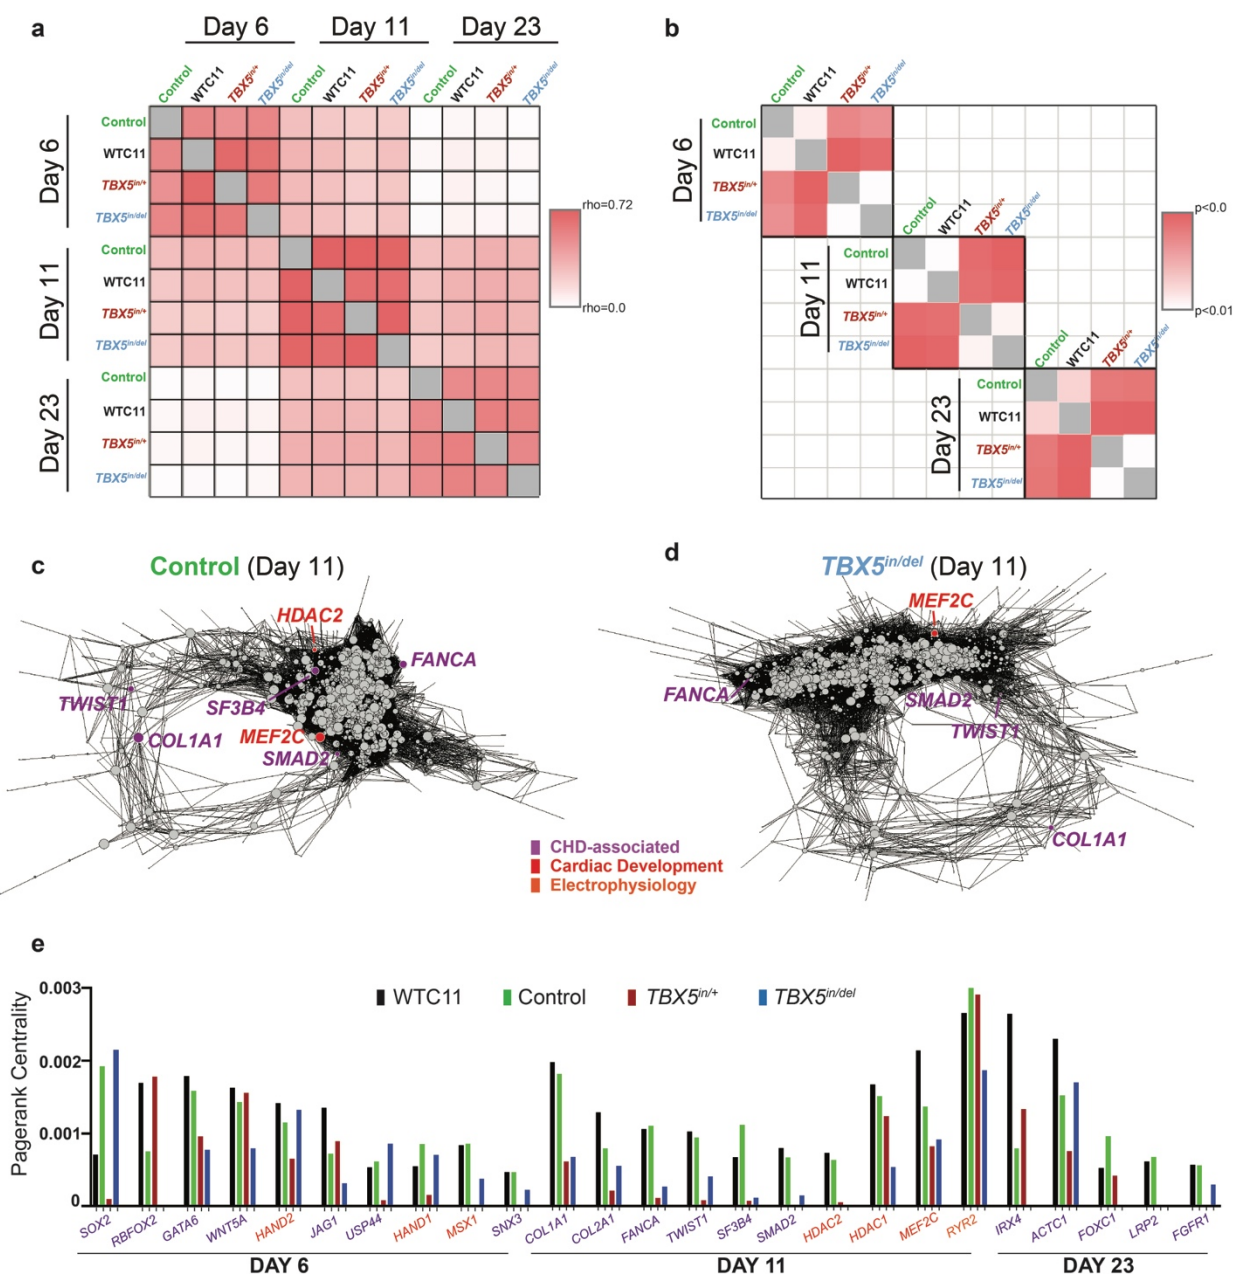

Extended Data 15. Analysis of TBX5 dosage-sensitive gene regulatory networks. **a,** Correlation plot (Pearson correlations of pagerank centralities) of networks by genotypes and time points are shown. Note that networks display highest similarity (red) within a time point. An inter-stage dissimilarity (white) grows proportionally to the time difference (i.e. Day 23 is less similar to Day 6 than Day 11). Therefore, comparisons for genotype differences were made within differentiation stages. **b,** Network similarity among genotypes within each time point is shown (Wilcoxon Rank Sum test of pagerank centralities for nodes from selected time point comparisons). **c, d,** Network diagrams of day 11 cardiomyocytes for control (**c**) or *TBX5^{in/del}* (**d**) are shown. **e**, Quantification of pagerank centrality for significantly altered (top 5% cutoff) nodes of CHD-associated or heart development genes at specific time points are shown.

1204
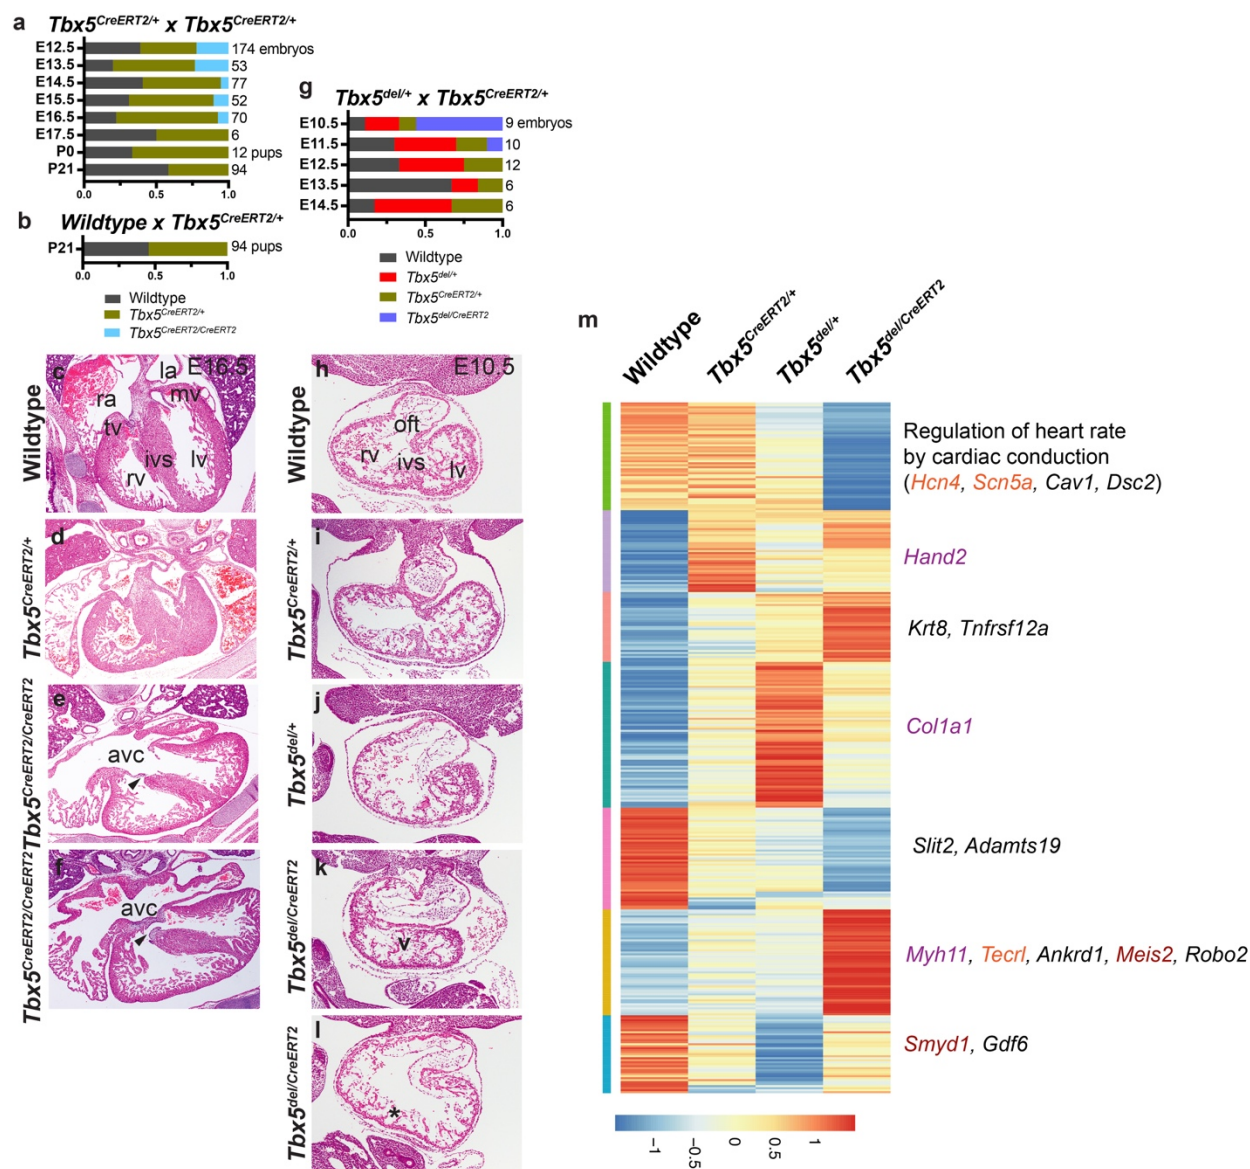

Extended Data 16. An allelic series of *Tbx5* mutants in mouse. a, Embryos or pups from matings of $Tbx5^{CreERT2/+}$ X $Tbx5^{CreERT2/+}$ were genotyped. Expected Mendelian ratios were not observed for $Tbx5^{CreERT2/CreERT2}$ after E13.5. **b,** Expected Mendelian ratios were observed for pups at weaning from matings of $Tbx5^{CreERT2/+}$ X wildtype. **c-f,** Transverse sections of hearts at embryonic day 16.5 (E16.5) from each genotype are shown. Right atrium (ra), left atrium (la), right ventricle (rv), left ventricle (lv), tricuspid valve (tv), mitral valve (mv) and interventricular septum (ivs) are labeled. Note atrioventricular canal defects (avc), which includes membranous VSDs (arrowheads), in $Tbx5^{CreERT2/CreERT2}$ hearts (**e, f**). **g,** Expected Mendelian ratios from matings of $Tbx5^{CreERT2/+}$ X $Tbx5^{del/+}$ were not observed for $Tbx5^{del/CreERT2}$ after E10.5. **h-l,** Transverse sections of individual hearts at embryonic E10.5 from each genotype are shown. Note a single ventricle (v) and lack of invagination (*) at the site of the nascent interventricular groove. **m,** Heat map by genotype of average gene expression data from 4 individual whole hearts at E10.5 (Supplementary Table 7). Significant GO term (adj p-value <0.05) for one cluster is shown, including underlying genes. TBX5-dependent mouse genes that are also

1220 TBX5-sensitive in human cells are shown. CHD-associated (purple), electrophysiology-related (orange), or heart development (red) genes are highlighted.

1222
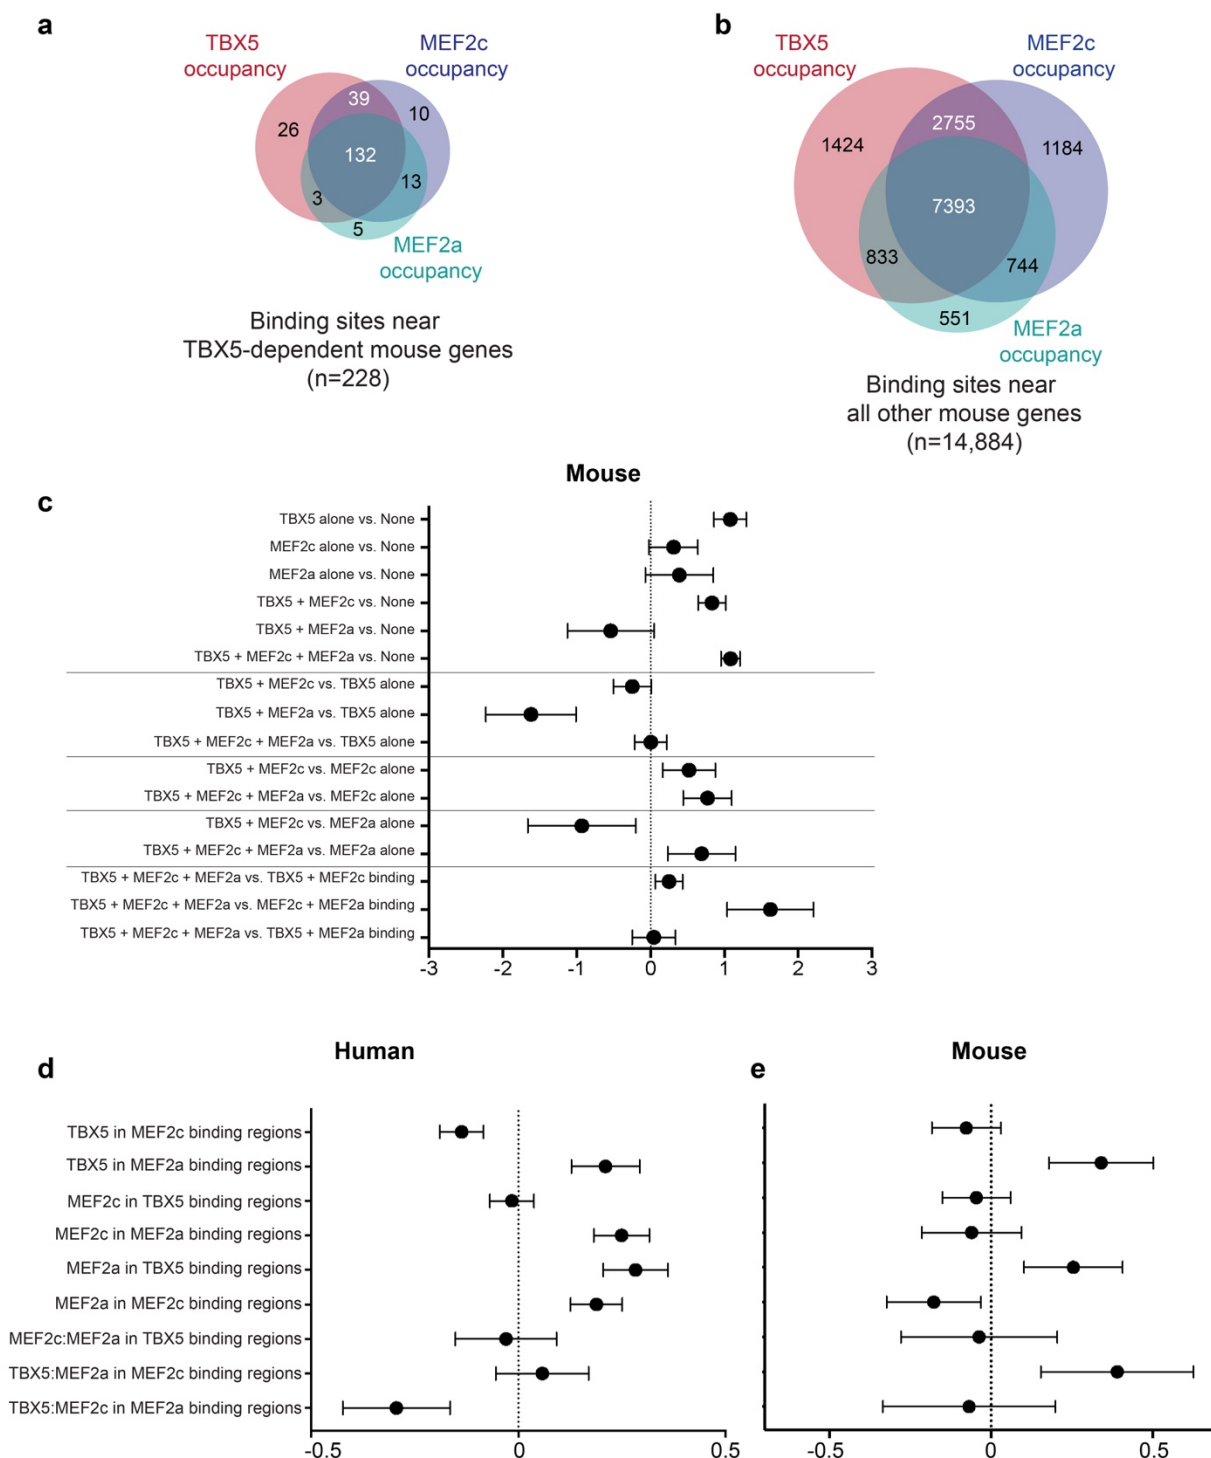

Extended Figure 17. Analyses of TBX5, MEF2c and MEF2a co-occupancy. a, b, Venn diagrams display the overlap of TBX5, MEF2a or MEF2c occupancy near mouse orthologs of human TBX5-dependent or -independent genes, respectively. **c,** Odds ratios (FDR<0.05) of combinations of TBX5, MEF2a or MEF2c occupancy near TBX5-dependent mouse genes

1232   (Supplementary Table 5). **d, e,** Odds ratios (FDR<0.05) of combinations of MEF2a or MEF2c
        occupancy within 1kb of TBX5 binding sites near TBX5-dependent or all other genes in human

1234   (**d)** or mouse (**e**) (Supplementary Table 8).

1236

1238

1240

1242
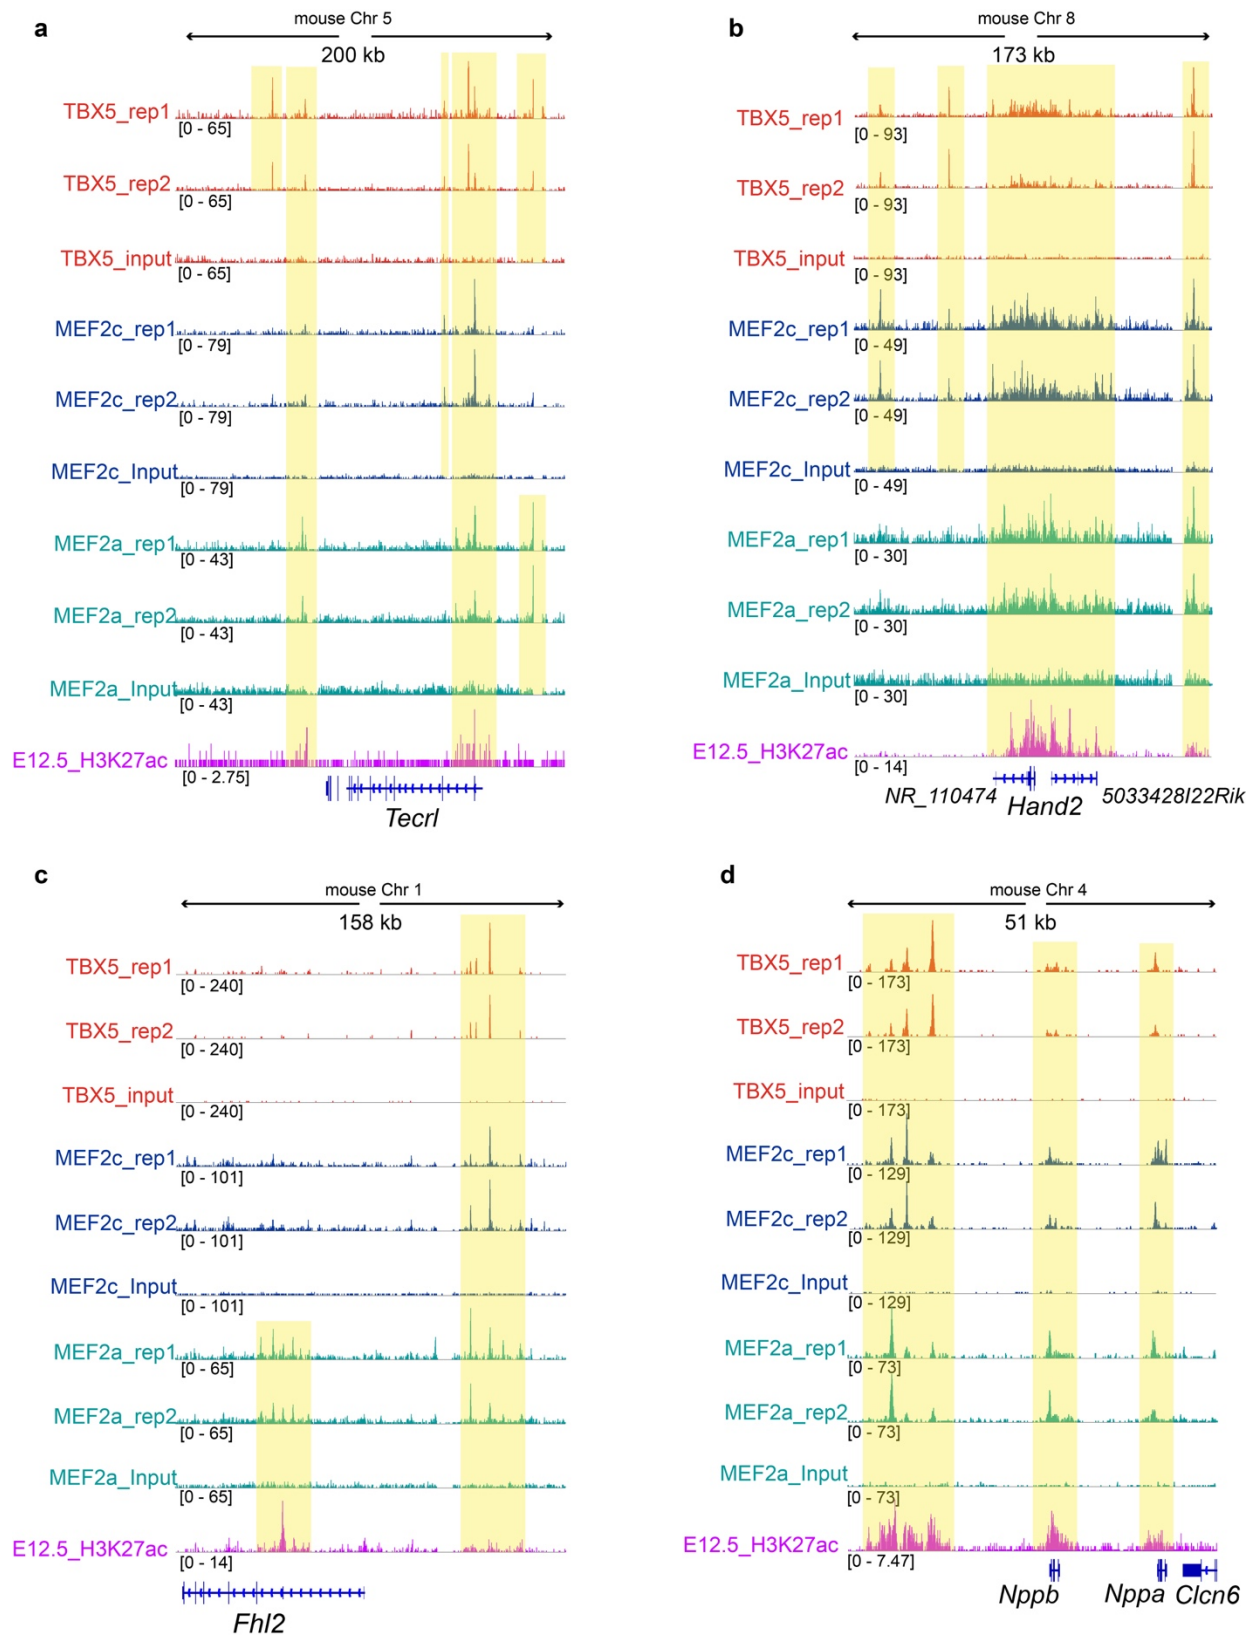

Extended Data 18. Co-occupancy of TBX5, MEF2a and MEF2c near TBX5-dependent genes. a-d, Browser tracks for ChIP-seq data from E12.5 hearts of TBX5, MEF2c, MEF2a and H3K27ac near conserved TBX5-dependent genes, *Hand2*, *Tecrl, Fhl2* and *Nppa/Nppb*. Yellow bands of shading indicate co-occupancy that is present in replicates but not in input.

Extended Data 19. Correlations of between disease candidates, GWAS reported genes, TBX5, MEF2c or MEF2a occupancy, or TBX5-dependent genes. a, Heat map indicates odds ratios (FDR<0.05) between several variables, including CHD-associated genes, EP-related genes, CHD-related GWAS reported genes, arrhythmia-related GWAS (EP-GWAS) reported genes, TBX5, MEF2c, or MEF2a occupancy, and TBX5-dependent human gene sets at day 11

1252   or day 23 or TBX5-dependent mouse gene sets (Supplementary Table 6). Statistical significance was determined by Benjamini-Hochberg multiple testing.

1254
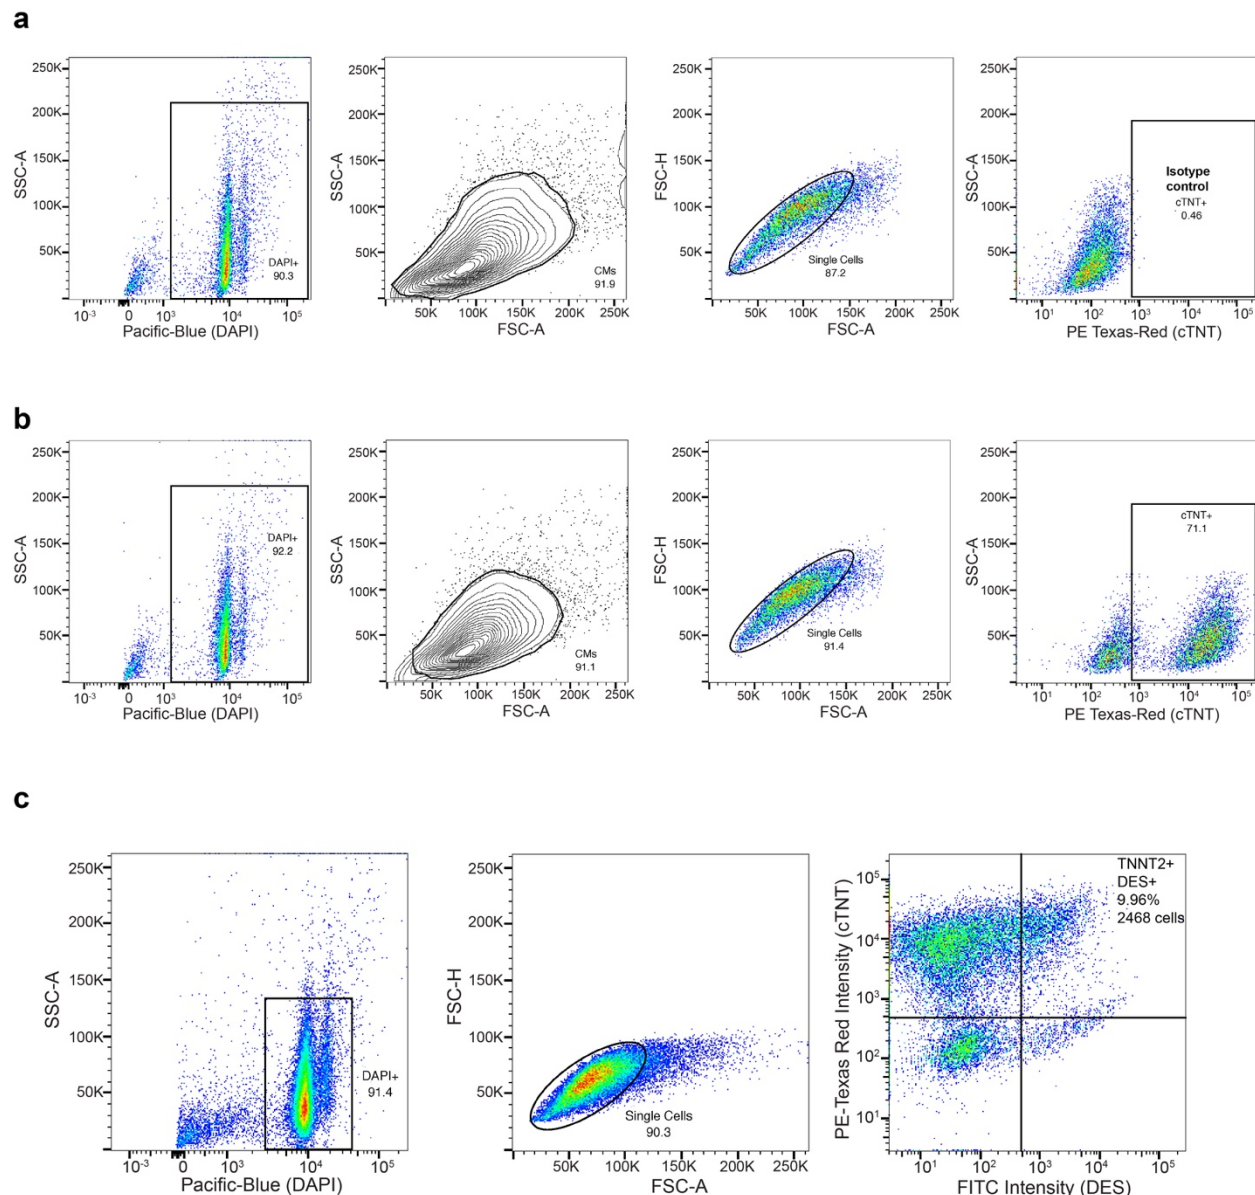

Extended Data 20. Gating strategies for flow cytometry. a, b, Gates were determined in each of the isotype controls per genotype and applied to genotype-matched samples. First, gates were drawn around DAPI$^+$ cells in SSC-A vs. Pacific-Blue plots. Next, SSC-A vs. FSC-A plots were used to exclude debris. Single cells were then isolated by gating of FSC-H vs. FSC-A plots. cTNT$^+$ gates were drawn in SSC-A vs. FITC plots. **c,** For cTNT$^+$/DES$^+$ cells, PE-Texas Red vs. FITC plots were used.

Supplementary Tables.

Supplementary Table 1. Curated gene lists, which are used in this study, include electrophysiology (EP)-related genes, human congenital heart disease (CHD)-associated genes, mouse CHD-associated genes and cardiac development-related genes.

Supplementary Table 2. Lists of differential genes from comparisons between *TNNT2*⁺ clusters, at day 11 or day 23, or by biological replicate or genetic background at day 23.

Supplementary Table 3. TBX5-sensitive gene regulatory network analyses, by pagerank or degree, or by correlation with *TBX5* or *MEF2C* expression.

Supplementary Table 4. Data for odds ratios for correlation of human TBX5-dependent genes near TBX5 or GATA4 occupancy, congenital heart disease (CHD)-associated GWAS, electrophysiology (EP)-related GWAS, CHD-associated genes, or EP-related genes.

Supplementary Table 5. Odds ratios for co-occupancy data near human TBX5-dependent genes for TBX5 and GATA4, or for co-occupancy of TBX5, MEF2c and MEF2a near human or mouse TBX5-dependent genes.

Supplementary Table 6. Data for odds ratios for correlation of human or mouse TBX5-dependent genes near TBX5, MEF2c or MEF2a occupancy, congenital heart disease (CHD)-associated GWAS, electrophysiology (EP)-related GWAS, CHD-associated genes, or EP-related genes.

Supplementary Table 7. Bulk RNAseq data of mouse embryonic hearts at E10.5 for an allelic series of *TBX5* mutants.

Supplementary Table 8. Odds ratio for transcription factor (TF) binding of TBX5, MEF2c, or MEF2a within 1kb of the other TFs in the trio, near human or mouse TBX5-depenedent genes.
