Running title: Megakaryocyte/platelet Mpl curb myeloproliferation
Abstract:

Thrombopoietin (TPO) acting via its receptor Mpl is the major cytokine regulator of platelet number. To precisely define the role of specific hematopoietic cells in TPO dependent hematopoiesis, we generated mice that express the Mpl receptor normally on stem/progenitor cells but lack expression on megakaryocytes and platelets (Mpl\textsuperscript{PF4cre/PF4cre}). Mpl\textsuperscript{PF4cre/PF4cre} mice displayed profound megakaryocytosis and thrombocytosis with a remarkable expansion of megakaryocyte-committed and multipotential progenitor cells, the latter displaying biological responses and a gene expression signature indicative of chronic TPO over-stimulation as the underlying causative mechanism, despite a normal circulating TPO level. Thus, TPO signaling in megakaryocytes is dispensable for platelet production; its key role in control of platelet number is via generation and stimulation of the bipotential megakaryocyte precursors. Nevertheless, Mpl expression on megakaryocytes and platelets is essential to prevent megakaryocytosis and myeloproliferation by restricting the amount of TPO available to stimulate the production of megakaryocytes from the progenitor cell pool.

Significance statement:

Blood platelets, the small circulating cells that co-ordinate hemostasis, are produced by specialized bone marrow cells called megakaryocytes. The cytokine thrombopoietin (TPO) is a key regulator of platelet production acting via its specific cell receptor, Mpl. Via genetic modification of the Mpl allele in mice, we precisely define the bone marrow cells that express Mpl and, by genetically removing Mpl from megakaryocytes and platelets, we show TPO signaling via Mpl is not required in megakaryocytes for their expansion, maturation or platelet production. Rather, Mpl expression on megakaryocytes is essential for regulating TPO availability in the bone marrow microenvironment to prevent myeloproliferation, a model we suggest is important for human disease.
Introduction:

Thrombopoietin (TPO) is the principal hematopoietic cytokine that regulates platelet production at steady state and is required for rapid responses to platelet loss. TPO acts by binding to a specific cell surface receptor, Mpl, leading to receptor dimerization, activation of intracellular signal transduction pathways and responses of target cells. Mice lacking TPO or Mpl are severely thrombocytopenic and deficient in megakaryocytes and their progenitor cells, a phenotype consistent with a role for TPO in maintaining appropriate megakaryocyte numbers in vivo. In addition to its role in megakaryopoiesis, TPO is also an indispensable regulator of hematopoietic stem cells (HSC), essential for maintenance of quiescence and self-renewal (1).

TPO is produced primarily in the liver (2) and upon binding to the Mpl receptor on target cells is internalised and degraded. The prevailing model posits that circulating TPO concentration is inversely proportional to the “Mpl-mass” contributed by the total number of megakaryocytes and platelets. In normal individuals this model describes an effective feedback system to regulate TPO-driven megakaryocyte and platelet production according to need. The reciprocal relationship between platelet number and circulating TPO level is clearly evident in bone marrow transplant patients (1), and the key role of the TPO receptor is illustrated by the elevated circulating TPO in Mpl<sup>-/-</sup> mice (3) and the modest elevation of platelet counts in transgenic mice expressing low levels of Mpl (4, 5). However, the relationship between circulating TPO concentration and peripheral platelet counts is not always conserved in pathological states of thrombocytosis and thrombocytopenia (6-9) suggesting that a simple relationship between megakaryocyte and platelet “Mpl-mass”, circulating TPO concentration and the degree of stimulation of megakaryopoiesis may not always hold.
While expression of Mpl on megakaryocytes and platelets contributes to regulation of available TPO, the role of direct TPO stimulation of megakaryocytes for effective platelet production is unclear. Administration of TPO in vivo or stimulation of bone marrow in vitro elevates megakaryocyte numbers and increases mean DNA ploidy (10, 11) and the thrombocytopenia in TPO−/− mice is accompanied by reduced megakaryocyte ploidy (12). However, while exposure of megakaryocytes to TPO stimulates intracellular signaling (13), in vitro studies suggesting direct action of TPO on megakaryocytes to increase DNA ploidy, promote cytoplasmic maturation or to stimulate proplatelet production (14-16) are balanced by reports that TPO is dispensable for these megakaryocyte functions (15, 17-19).

To comprehensively define Mpl-expressing stem and progenitor cell populations in vivo and resolve the specific requirements for Mpl expression in megakaryocytes and platelets for platelet production and feedback control of TPO levels, we generated a novel mouse strain in which green fluorescent protein (GFP) is expressed from the Mpl locus and, when crossed to Platelet Factor 4(PF4)cre transgenic mice (20), specifically lacks Mpl expression in megakaryocytes and platelets.

Results

A targeting vector was constructed for generation, via homologous recombination in embryonic stem cells, of a modified Mpl allele (Mplfl/fl) designed to retain Mpl expression and provide a green fluorescent protein (GFP) reporter for transcriptional activity of the Mpl locus. The inclusion of loxP sites allowed for cre recombinase-mediated deletion of the GFP reporter as well as exons 11 and 12, resulting in a null allele (Fig. 1A and SI Materials and Methods). PF4-cre transgenic mice (20) have been reported to allow specific and efficient deletion of conditional alleles in megakaryocytes and platelets. To verify the activity and cell-type specificity of PF4-cre mice, particularly in view of a recent report of activity in HSCs (21), we crossed PF4-cre mice to mice in which enhanced yellow fluorescent protein (EYFP) is expressed in a cre-dependent manner.
While, as expected, EYFP was not expressed in the absence of cre recombinase, in Rosa26EYFP<sup>Pf4<sup>Cre</sup></sup> mice EYFP was expressed in megakaryocytes and platelets, consistent with previous reports (20) and not in erythroid, lymphoid or myeloid cells (“SI Appendix, Fig. S1A”). Megakaryocyte formation progresses from a series of TPO-responsive bipotential erythroid-megakaryocyte progenitors (23). EYFP was not expressed in Lineage-negative Sca-1<sup>+</sup> Kit<sup>+</sup> (LSK) bone marrow cells, the population containing stem and primitive multipotential progenitor cells, nor in any progenitor cell fraction tested, including the BEMP and CD150<sup>+</sup>CD9<sup>hi</sup> megakaryocyte/erythroid-restricted bipotential megakaryocyte-erythroid progenitor population and CFU-E erythroid progenitor population (“SI Appendix, Table S1, Fig. S1B,C”). EYFP expression was observed in a proportion of cells in a previously uncharacterised CD150<sup>+</sup>Fcer<sup>+</sup> population (Lin<sup>-</sup>Sca-1<sup>-</sup>Kit<sup>-</sup>CD150<sup>+</sup>IL7RαFcyRII/III<sup>+</sup>Endoglin<sup>lo</sup>CD9<sup>hi</sup>, “SI Appendix, Fig. S1B,C”) that comprised ~ 0.01% of the bone marrow (“SI Appendix, Fig. S2A”) and which demonstrated potent erythro-megakaryocytic potential in vitro and in vivo (“SI Appendix, Fig. S2B,C”). We conclude that the CD150<sup>+</sup>Fcer<sup>+</sup> fraction includes megakaryocyte precursors downstream from the previously characterised CD150<sup>+</sup>CD9<sup>+</sup> fraction, revealed by the onset of Pf4 promoter activity that, given the lack of YFP expression in CFU-E in Rosa26EYFP<sup>Pf4<sup>Cre</sup></sup> mice, may define a megakaryocyte-restricted precursor within the bipotential CD150<sup>+</sup>Fcer<sup>+</sup> fraction. Thus cre-dependent recombination using the Pf4-cre transgenic mouse was restricted to late megakaryocyte progenitors, megakaryocytes and platelets and absent in other progenitor cells and hematopoietic lineages.

**Mpl expression is absent in megakaryocytes and platelets, but retained in megakaryocyte progenitor and stem cells in Mpl<sup>PF4<sup>cre</sup>/PF4<sup>cre</sup></sup> mice.**

To investigate the physiological effects of Mpl deletion on megakaryocytes and platelets we crossed Mpl<sup>fl/fl</sup> mice to PF4cre mice to produce progeny in which the intracellular domain of Mpl and the IRES-GFP cassette had been specifically deleted in megakaryocytes and platelets
Western blot analysis of extracts from megakaryocytes and platelets demonstrated efficient ablation of Mpl expression in MplPF4cre/PF4cre mice (Fig. 1B). This was confirmed by analysis of Mpl-GFP reporter expression: while megakaryocytes generated in culture from Mpl^{fl/fl} mice expressed GFP, this was lost in MplPF4cre/PF4cre mice, consistent with recombination and deletion of the targeted Mpl^{fl} intracellular domain and IRES-GFP cassette in these cells (“SI Appendix, Fig. S3A”, Fig. 1A), and consequently, absence of GFP in platelets (“SI Appendix, Fig. S3B”). As anticipated, no activity of the Mpl locus was evident in lymphocytes, granulocytes or erythroid cells (“SI Appendix, Fig. S3B”). In LSK cells, MplPF4cre/PF4cre mice expressed Mpl at equivalent levels to Mpl^{fl/fl} controls, both via flow cytometry with anti-Mpl antibody, and via the Mpl-GFP reporter (Fig. 1C,D and “SI Appendix, Fig. S3C,D”). As expected, Mpl expression was not detected in pre-granulocyte-macrophage (preGM) or granulocyte-macrophage (GMP) progenitor cells, nor in CFU-E. In Mpl^{fl/fl} control megakaryocyte progenitor cells, Mpl expression first became apparent in BEMP and was maintained in maturing CD150⁺CD9^{hi} and CD150⁺FcγR^{+} progenitor cells. As expected Mpl was not detected in any cell populations examined in previously generated Mpl^-/- mice (24), nor via the Mpl-GFP reporter in MplDelcre/Delcre control mice, in which Mpl^{fl/fl} mice were crossed to Deleter-cre transgenic mice (25) to generate mice in which the Mpl^{fl} locus including the IRES-GFP reporter cassette were deleted throughout the animal. Importantly, Mpl expression was unperturbed in MplPF4cre/PF4cre BEMP and CD150⁺CD9^{hi} megakaryocyte-biased bipotential progenitors, but reduction in Mpl IRES-GFP transcription and cell surface Mpl expression was apparent in MplPF4cre/PF4cre CD150⁺FcγR^{+} megakaryocyte precursors.

Thus, in MplPF4cre/PF4cre mice, Mpl expression was intact in LSK and early bipotential erythromegakaryocytic progenitor cells, reduced in later progenitors with megakaryocyte potential and absent in megakaryocytes and platelets. The pattern of ablation of Mpl expression in MplPF4cre/PF4cre mice was entirely consistent with the activity of PF4-cre defined in Rosa26EYFP^{PF4Cre} mice.

**MplPF4cre/PF4cre mice develop a marked thrombocytosis and megakaryocytosis**
While $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice were healthy and displayed no outward abnormalities, analysis of peripheral blood (Table 1) revealed a remarkable thrombocytosis with a 10-fold increase in the number of circulating platelets in comparison to $\text{Mpl}^{\text{fl/fl}}$ or $\text{Mpl}^{+/+}$ controls. In contrast, and as expected, $\text{Mpl}^{\text{Delcre/Delcre}}$ exhibited a profound thrombocytopenia identical in phenotype to previously reported $\text{Mpl}^{+/+}$ mice (24). In contrast, the numbers of other blood cells in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice were not significantly different from $\text{Mpl}^{\text{fl/fl}}$ or $\text{Mpl}^{+/+}$ controls. Significant splenomegaly was evident in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice ($\text{Mpl}^{\text{PF4cre/PF4cre}}$ 210±46 mg, $\text{Mpl}^{\text{fl/fl}}$ 76±15 mg, n=4 per genotype, $P=0.0012$) with histology revealing gross megakaryocytosis in the bone marrow and spleen, with the numbers of megakaryocytes in these organs even greater than observed in transgenic mice ($\text{TPO}^\text{Tg}$, (3)) engineered to express high amounts of TPO (Fig. 2A, “SI Appendix, Fig. S4A”). Both $\text{Mpl}^{\text{PF4cre/PF4cre}}$ and $\text{TPO}^\text{Tg}$ mice had a significant increase in the proportion of megakaryocytes with ploidy of 16N or greater relative to $\text{Mpl}^{\text{fl/fl}}$ controls (Fig. 2B). Clonogenic assays of bone marrow and spleen cells revealed a profound increase in the numbers of megakaryocyte colony-forming cells in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice (Table 2). The profound thrombocytosis in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ was not accompanied by significant extension in platelet lifespan (“SI Appendix, Fig. S4B”). Together, these data suggest that the thrombocytosis in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice is caused primarily by excess production of megakaryocytes and their progenitors.

$\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice have perturbed stem and progenitor cell compartments and develop features of myeloproliferation

In addition to excess numbers of megakaryocyte progenitor cells, the total number of myeloid progenitor cells in the bone marrow and spleen of $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice was also significantly elevated, with a particular increase in the number of blast colony-forming cells, a phenotype also observed in the bone marrow of $\text{TPO}^\text{Tg}$ mice (Table 2). HSC and myeloid progenitor cell populations were analysed by flow cytometry, with particular emphasis on cells with megakaryocyte potential. $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice displayed a two- to four-fold increase in bone
marrow LSK cells, Lin- cKit- Sca1+ myeloid progenitors, pre-granulocyte-macrophage (PreGM) progenitors, GM progenitors (GMP) and CD150+CD9hi and CD150+FcγR+ bipotential erythroid-megakaryocyte progenitor populations, with a reduction in erythroid progenitors (preCFU-E and CFU-E) when compared to Mpl+/+ and/or Mplfl/fl controls (Fig. 3, “SI Appendix, Fig. S5”). This was similar to the effects caused by chronic excessive in vivo TPO stimulation (TPOTr, Fig. 3, “SI Appendix, Fig. S5” and (23)), but was significantly more marked in MplPF4cre/PF4cre mice.

Blast cell colonies, which represent primitive multi-potential pre-progenitor cells (26) predominantly derived from the LSK population (27, 28) were picked from primary cultures and replated. Blast cell colonies from MplPF4cre/PF4cre mice had a significantly increased propensity to formation of secondary colonies, an effect also evident in TPOTr mice, particularly secondary blast cell and megakaryocyte colonies (“SI Appendix, Fig. S6”), demonstrating a greater in vitro capacity for pre-progenitor cell self-renewal and secondary colony formation when compared to Mplfl/fl controls. This provides evidence at the single cell level that MplPF4cre/PF4cre multipotential pre-progenitor cells, like those in TPOTr mice, have characteristics of chronic excessive TPO exposure.

**Stem and progenitor cells expressing Mpl are responsible for TPO clearance in MplPF4cre/PF4cre mice**

Circulating TPO concentrations were assayed to determine how serum TPO levels were affected by loss of Mpl expression on megakaryocytes and platelets in MplPF4cre/PF4cre mice. As expected, TPOTr mice, engineered to express excess TPO, and Mpl+/+ mice, which have no capacity to clear serum TPO by Mpl receptor-mediated endocytosis, had elevated levels of serum TPO (Fig. 4A). Surprisingly, the circulating TPO level in MplPF4cre/PF4cre mice, was not significantly different from Mplfl/fl controls. Transcription of TPO in the liver, the major site of TPO production, was unaltered in MplPF4cre/PF4cre mice (Fig. 4B). This finding implies that Mpl-expressing LSK and megakaryocyte/erythroid progenitor cells in MplPF4cre/PF4cre mice, which are expanded significantly
in number, clear circulating TPO to levels observed in Mpl-replete mice, even in the absence of clearance by megakaryocytes and platelets.

**Gene expression profiling of Mpl<sup>PF4cre/PF4cre</sup> stem and primitive progenitors demonstrate a TPO stimulation signature**

Gene expression profiling was undertaken on sorted LSK populations from Mpl<sup>+/+</sup>, TPO<sup>tg</sup>, Mpl<sup>−/−</sup>, Mpl<sup>0/0</sup> and Mpl<sup>PF4cre/PF4cre</sup> mice using Illumina WG version 2 bead-chip microarrays. Pair-wise comparison between Mpl<sup>PF4cre/PF4cre</sup> and Mpl<sup>0/0</sup> LSKs was performed to obtain differentially expressed genes using a linear modeling and an empirical Bayes approach (29), “SI Appendix, Table S2, and SI Materials and Methods”). Signature genes of TPO<sup>tg</sup> LSKs and Mpl<sup>/−</sup> LSKs were defined as those that were significantly differentially expressed in a positive direction by pair-wise comparison to wild-type LSKs (“SI Appendix, Table S3, S4”). Rotational gene set tests were then performed using ROAST (30) with the "TPO over-stimulation" gene signature from TPO<sup>tg</sup> LSKs and the "TPO starvation" gene signature from Mpl<sup>/−</sup> LSKs. This analysis revealed that genes associated with TPO overstimulation in TPO<sup>tg</sup> LSKs were strongly correlated with upregulated genes in Mpl<sup>PF4cre/PF4cre</sup> LSKs whereas the gene signature associated with TPO starvation in Mpl<sup>/−</sup> LSKs was associated with downregulated genes in Mpl<sup>PF4cre/PF4cre</sup> LSKs (Fig. 4C). This data confirms at a genetic level that Mpl expressing stem and progenitor cells in Mpl<sup>PF4cre/PF4cre</sup> mice were exposed to excessive TPO stimulation, explaining the behaviour of their pre-progenitor blast colonies at the single cell level and the mechanistic basis for the myeloproliferation, megakaryocytosis and thrombocytosis observed in Mpl<sup>PF4cre/PF4cre</sup> mice.

**Human CD34<sup>+</sup> stem and progenitor cells demonstrate a Mpl<sup>PF4cre/PF4cre</sup> LSK gene expression signature**

Megakaryocytes and platelets in human myeloproliferative neoplasms have been shown to express reduced levels of MPL (31, 32). To explore the possibility that reduced MPL expression on
megakaryocytes and platelets in human disease might contribute to the myeloproliferative phenotype via a mechanism analagous to the excessive TPO stimulation of stem and progenitor cells evident in the \(Mpl^{PF4cre/PP4cre}\) model, we compared the gene expression signature of \(Mpl^{PF4cre/PP4cre}\) LSK cells (“SI Appendix, Table S2”) to gene expression in CD34\(^+\) bone marrow cells from patients with mutated \(JAK2V617F\) and \(JAK2\) wild-type essential thrombocythemia (GEO database GSE9827, (33)). Rotational gene set testing demonstrated significant enrichment of the \(Mpl^{PF4cre/PP4cre}\) LSK gene signature (\(P = 1.48 \times 10^{-2}\), Fig. 4D) and \(TPO^{Tg}\) and \(Mpl^{-/-}\) LSK gene signatures (\(P = 8 \times 10^{-4}\), “SI Appendix, Fig. S7”) in CD34\(^+\) cells from patients with disease. Thus, reduced expression of Mpl in megakaryocytes and platelets resulting in the excessive TPO stimulation of stem and progenitor cells that characterises \(Mpl^{PF4cre/PP4cre}\) mice may in part underpin the pathogenesis of megakaryocytosis and thrombocytosis in human myeloproliferative disease.

**Discussion**

While it has been established TPO signaling is required for maintaining steady state platelet numbers and response to crises requiring rapid platelet production, the precise cellular mechanisms by which TPO actions are achieved remained largely undefined. Our results definitively establish that 1) Mpl expression on megakaryocytes is dispensable for high level platelet production and megakaryocyte maturation, 2) the primary mechanism by which TPO signaling stimulates thrombopoiesis is via Mpl-expressing hematopoietic progenitors, and 3) Mpl receptor on megakaryocytes and platelets acts predominantly, if not solely to regulate, via internalization and degradation, the amount of TPO available to hematopoietic stem and progenitor cell populations (Fig. 5).

Regarding the role of Mpl expression on megakaryocytes, while increased megakaryocyte ploidy has been associated with high TPO activity and the converse has been observed in TPO/Mpl-deficient mouse models (3, 10-12), a shift to higher ploidy megakaryocytes accompanied marked
thrombocytosis in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice was observed despite the absence of Mpl expression in megakaryocytes. Thus, thrombopoiesis and the development of high DNA ploidy in megakaryocytes is independent of TPO signaling in these cells; the latter likely reflecting alternative mechanisms associated with states of increased megakaryocyte production. A role for TPO in sensitizing platelets to specific activators (34) may explain the retention of Mpl signaling pathways in megakaryocytes and platelets as our data do not exclude TPO, when functional Mpl is present, having a positive effect on megakaryocyte or platelet function.

Notably, $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice exhibited all the phenotypic hallmarks and gene expression changes in stem/primitive multipotential progenitor cells, indicative of chronic excessive TPO stimulation. This was despite having normal concentrations of serum TPO. These data support a model in which absence of megakaryocyte and platelet Mpl mass allows greater available TPO for stimulation of Mpl-expressing stem/progenitor cells, the expansion of which normalises the circulating TPO concentration via Mpl-mediated internalisation. Thus, the circulating TPO concentration in this model is determined by the Mpl mass of both the megakaryocyte/platelet pool and Mpl-expressing stem and progenitor cells. Moreover, as $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice were observed to have a more profound myeloproliferative phenotype with a greater degree of thrombocytosis relative to $\text{TPO}^{\text{Tg}}$ counterparts, despite the latter having a higher circulating TPO level, suggests local TPO availability within the stem and progenitor cell microenvironment of the bone marrow may be regulated in significant part by megakaryocytes: $\text{TPO}^{\text{Tg}}$ mice would retain megakaryocyte Mpl-mediated regulation of local TPO contentration, while absence of functional Mpl on megakaryocytes in $\text{Mpl}^{\text{PF4cre/PF4cre}}$ mice, would significantly impair local TPO regulation. Increasingly, evidence has suggested a close physical relationship between megakaryocytes and bone marrow stem/progenitor cell niches. Imaging studies have identified megakaryocytes co-localising with CD150⁺CD48⁻Lin⁻ HSCs adjacent to sinusoidal endothelium (35) as well as in close
proximity to Nestin⁺ mesenchymal stem cells, which form a significant functional component of the HSC niche (36).

The importance of TPO as a multi-functional regulator of hematopoiesis was highlighted. Chronic TPO overstimulation in $Mpl^{PP4cre/PF4cre}$ and $TPO^{Tg}$ mice resulted in excess numbers of primitive multipotential pre-progenitor blast colonies that are principally derived from LSK cells, a population that expresses Mpl. The increased propensity of pre-progenitor cells to self-renew and to produce increased numbers progenitors of multiple myeloid lineages with chronic TPO overstimulation provide a mechanistic rationale for the effectiveness of the TPO mimetic agent eltrombopag in the restoration of bone marrow cellularity and multi-lineage haemopoiesis in patients with severe refractory aplastic anemia (37). Additionally, megakaryocyte lineage skewing of pre-progenitor cells derived from $Mpl^{PP4cre/PF4cre}$ mice suggests excessive TPO stimulation may also act during these earlier stages in the hematopoietic hierarchy for megakaryocyte lineage specification. In more differentiated progenitors, identification of Mpl receptor expression on bipotential progenitor populations that were expanded in $Mpl^{PP4cre/PF4cre}$ mice and were associated with megakaryocytosis and a relative paucity of erythroid precursors, confirms our previous findings (23). Thus, bipotential erythro-megakaryocytic progenitors express Mpl and are critical effector cells of TPO-dependent thrombopoiesis that are driven to differentiate into megakaryocytes in response to TPO, and which under conditions of excessive TPO stimulation, are skewed toward megakaryocytopoiesis at the expense of erythropoiesis. Despite increased number of diverse myeloid progenitor cells in $Mpl^{PP4cre/PF4cre}$ mice, the number of circulating white blood cells was not consistently elevated, suggesting the contribution of other regulatory mechanisms in control of mature granulocyte and macrophage number.

Finally, the demonstration that the chronic TPO stimulation gene expression signature in LSK cells of $Mpl^{PP4cre/PF4cre}$ mice was also evident in the gene expression changes in human bone marrow
CD34$^+$ cells from patients with essential thrombocytethemia, provides an important potential explanation for the observation that abnormally low expression of MPL in platelets and megakaryocytes of human patients with myeloproliferative disorders is associated with thrombocytosis (31, 32). Our data support a model that such disorders may be in part underpinned by insufficient MPL mass within the platelet/megakaryocyte pool resulting in increased TPO stimulation of the MPL expressing stem and progenitor cells similar to that observed in $Mpl^{PF4cre/PF4cre}$ mice.
Materials and Methods:

Mice were analysed at age 7-12 weeks. $TPO^{Tr}$ (3) and $Mpl^{-/-}$ (24) mice have been previously described. See “SI Appendix, SI Materials and Methods” for generation of $Mpl^{fl/fl}$, $Mpl^{Delcre/Delcre}$ and $Mpl^{PF4cre/PF4cre}$ mice. Experiments were performed using procedures approved by The Walter and Eliza Hall Institute of Medical Research Animal Ethics Committee. Haematology, histology, clonal analysis of bone marrow cells semisolid agar cultures, liquid cultures of progenitor cells, flow cytometry, megakaryocyte analysis, Western blot analysis, platelet life span, serum TPO measurement, reverse transcription PCR, statistical analysis and bioinformatic analysis are described in “SI Appendix, SI Materials and Methods”. Microarray data are available at Array Express (www.ebi.ac.uk/arrayexpress/) under accession number E-MTAB-2389.

Fig. 4. TPO transcription, circulating TPO concentration and gene expression changes in LSK cells of Mpl$^{PF4cre/PF4cre}$ mice.

(A) TPO concentration by immunoassay in serum from Mpl$^{+/+}$, Mpl$^{\beta\beta}$/, Mpl$^{PF4cre/PF4cre}$, Mpl$^{+/}$ and TPO$^{\Delta}$ mice. * = $P < 0.04$, n= 10-17 mice per genotype. (B) TPO expression in livers determined by quantitative RT-PCR with $\Delta$CT shown as mean and standard deviation relative to GAPDH expression. There were no significant differences between Mpl$^{+/+}$, Mpl$^{\beta\beta}$/, Mpl$^{PF4cre/PF4cre}$, Mpl$^{+/}$ and TPO$^{\Delta}$ genotypes, n= 3-5 mice per group. (C) Barcode plot showing ability of TPO$^{\Delta}$ "TPO stimulated" LSK signature genes and Mpl$^{+/}$ "TPO starved" signature genes (see “SI Appendix, Table S3, S4”) to distinguish between Mpl$^{PF4cre/PF4cre}$ LSKs and Mpl$^{\beta\beta}$/ LSKs, with corresponding $P$ values derived from
rotational gene set testing using ROAST. Red bars designate upregulated genes in the TPO
tg “TPO stimulated” LSK signature set (P = 2x10^-4); blue bars designate Mplfl/fl
”TPO starved” LSK signature set (P = 8x10^-4); demonstrating gene expression in MplPF4cre/PF4cre
LSKs is strongly correlated with a “TPO stimulated” gene signature. (D) Barcode plot showing the TPO stimulated
gene expression signature of MplPF4cre/PF4cre LSKs (Red bars, upregulated genes; Blue bars,
downregulated genes, see “SI Appendix, Table S2”) can distinguish between CD34+ bone marrow
cells of patients with essential thrombocythemia from controls ((33) GEO database GSE9827, P =
1.48x10^-2). P value derived from rotational gene set testing using ROAST with the MplPF4cre/PF4cre
LSK gene signature weighted by log fold-change (see “SI Appendix, Table S2, see also Fig. S7 and
SI Materials and Methods”).

Fig. 5. Model for regulation of TPO and control of megakaryopoiesis.
(Top panel) Clearance of TPO by Mpl-expressing megakaryocytes in bone marrow and the
peripheral blood platelet pool maintains TPO homeostasis at steady state and in situations of acute
thrombocytopenia. For definitions of cell populations, see “SI Appendix, Table S1”. Mpl expression
is shown as blue bars for each population in Mplfl/fl mice. (Bottom panel) Loss of TPO clearance by
megakaryocytes and platelets leads to excessive TPO stimulation of Mpl-expressing HSCs and
progenitor cells, multi-lineage progenitor expansion and differentiation towards the megakaryocyte
lineage from bi-potential megakaryocyte-erythroid progenitors, with consequent myeloproliferation,
megakarytosis and thrombocytosis. While the availability of TPO for stimulation of
stem/progenitor cells is increased, consumption by the expanded numbers of these cells normalises
circulating TPO concentration. PF4-cre expression is shown as green bars and Mpl expression is
shown as blue bars for each population in MplPF4cre/PF4cre mice.
