Abstract

The origin of angiosperms has been the focus of intensive botanical debate for well over a century. The great diversity of angiosperms in the Early Cretaceous makes the Jurassic rather expected to elucidate the origin of angiosperm. Former reports of early angiosperms are frequently based on a single specimen, making many conclusions tentative. Here, based on observations of 284 individual flowers preserved on 28 slabs in various states and orientations, we describe a fossil flower, *Nanjinganthus dendrostyla* gen. et sp. nov., from the South Xiangshan Formation (Early Jurassic) of China. The large number of specimens and various preservations allows us to give an evidenced interpretation of the flower. The complete enclosure of ovules in *Nanjinganthus* is fulfilled by a combination of an invaginated and ovarian roof. Characterized by its actinomorphic flower with a dendroid style, cup-form receptacle, and angio-ovule, *Nanjinganthus* is a *bona fide* angiosperm from the Jurassic. *Nanjinganthus* re-confirms the existence of Jurassic angiosperms and provides first-hand raw data for new analyses on the origin and history of angiosperms.

Keywords: flower, fossil, Jurassic, China, gymnosperms, angiosperms.

Introduction

Despite the importance of angiosperms, a controversy remains as to when and how this group came into existence. Since the time of Darwin, some scholars have proposed that angiosperms existed before the Cretaceous (Smith *et al.* 2010; Clarke *et al.* 2011; Zeng *et al.* 2014; Buggs 2017), although others have favored a Cretaceous origin (Scott *et al.* 1960; Herendeen *et al.* 2017). Such uncertainties make the phylogeny and systematics of angiosperms tentative. Some reports of early angiosperms (i.e., *Monetianthus* (Friis *et al.* 2001)) are based on a single specimen and are thus difficult to test and confirm. Better and more specimens of indisputable age are preferred to test related hypotheses. Here, we report an unusual actinomorphic flower, *Nanjinganthus* gen. nov., from the Lower Jurassic based on the observations of 284 individual flowers preserved on 28 slabs in various orientations and states (Table S1). The abundance of specimens allowed us to dissect some of them and thus demonstrate and recognize a cup-form receptacle, ovarian roof, and enclosed ovules in *Nanjinganthus*. These features, in addition to actinomorphic organization, indicate that *Nanjinganthus* is a true flower of an angiosperm. The origin of angiosperms has long been an academic “headache”, but we think that *Nanjinganthus* will shed a new light on the subject.

Results

Genus *Nanjinganthus* gen. nov.

Generic diagnosis: Flowers subtended by bracts. Bracts fused basally. Flowers pedicellate, probably bisexual, actinomorphic, including four whorls of organs, epigynous, with inferior ovary. Sepals 4-5, more or less rounded in shape, with two lateral rib-free wings, attached to the receptacle rim with their whole bases, each with about four longitudinal ribs in the center, surrounding the petals when immature but reflexing when mature, with epidermal cells with straight cell walls. Petals 4-5, cuneate, concave, and with two lateral rib-free wings, with rounded tips and about four longitudinal ribs in the center, surrounding the gynoecium when immature but reflexing when mature, with epidermal cells with straight cell walls. Possible stamen including a stalk and four pollen sacs. Gynoecium in the center, unilocular, secluded by a cup-form receptacle from the bottom and sides and by an integral ovarian roof from the above. Style centrally located on the top of the ovarian roof, dendroid-formed. At least two ovules inside the ovary, elongated oval, pendulous and inserted on the ovarian wall by a thin funiculus, with the micropyle-like depression almost opposite the chalaza.

Type species: *Nanjinganthus dendrostyla* gen. et sp. nov.

Etymology: *Nanjing*-for Nanjing, the city where the specimens were discovered, and *-anthus* for “flower” in Latin.

Type locality: Wugui Hill, Sheshan Town, Xixia District, Nanjing, China (N32°08'19", E118°58'20") (Figs. S1).

Horizon: The South Xiangshan Formation, the Lower Jurassic.

Species *Nanjinganthus dendrostyla* gen. et sp. nov.
(Figs. 1-5; Figs. S4h, S5-S10)

Specific diagnosis: the same as the genus.

Description: The flowers are frequently concentrated and preserved in groups on certain bedding surfaces (Figs. 1a-b).

Flower bud A flower bud is preserved as a coalified compression, 6.4 mm long and 3 mm wide, with characteristic longitudinal ribs on the sepals and petals (Fig. 1g). The sepals are 1.3-2.2 mm long and approximately 1.8 mm wide (Fig. 1g). The petals are approximately 3.7 mm long (Fig. 1g). The receptacle/ovary is approximately 3 mm in diameter (Fig. 1g).

Figure 1 Flowers preserved in different states and their details. Bar = 1 mm except otherwise annotated.

A. Numerous flowers preserved on a single slab. The numbered ones are detailed in the later figures. PB22222B. Bar = 1 cm. **B.** Numerous coalified flowers on the same slab. The numbered ones are detailed in later figures. The possible stamen in Fig. 4i is from flower 4. PB22223. Bar = 1 cm. **C.** Bottom view of Flower 1 in Fig. 1a, showing 5 sepals (s) and 5 petals (p) with longitudinal ribs. PB22222B. **D.** Bottom view of Flower 2 in Fig. 1a, showing 4 sepals (s) and 4 petals (p) with longitudinal ribs. PB22222B. **E.** Bottom view of the flower in Fig. S6f, showing a sepal (s) and three petals (p) radiating from the center, which is broken to show the relationship among the sepals and petals as in Fig. 1j. PB22278. **F.** Top view of Flower 1 in Fig. S5b with sepals (s), petals (p), and seeds (arrow, enlarged in Fig. 3h) inside the receptacle. PB22226. **G.** Side view of a flower bud (No. 1 in Fig. 1b) with longitudinal ribs (arrows) on the sepals (s) and petals (p). PB22223. **H.** Side view of Flower 1 in Fig. S5d, showing a receptacle (h), petals and sepals (black arrows), and a dendroid style (white arrow). PB22224. **I.** Side view of Flower 2 in Fig. S5d, showing petals (black arrow), the dendroid style (white arrow), and the scale (b) on the receptacle. PB22224. **J.** Detailed view of an oblique section of the flower shown in Fig. 1e, showing the arrangement of three petal bases (1-3) inside the sepals (s). These petals bases correspond to the three petals (1-3) in Fig. 1e.

Mature flower The flowers are preserved in various states (including coalification), epigynous with an inferior ovary, 8.4-10.7 mm in length and 6.8-12.8 mm in diameter, actinomorphic in the bottom and top views (Figs. 1c-i, 2a, e, 3a-f, S4h, S5a-e, S6a-b, d-i, S7a-b,d,g, S8d-h). The pedicel is approximately 12 mm in length and 0.76 mm in diameter (Figs. 3a, b, j, l). Basally fused bracts are observed at the bottom in a few flowers, and a stoma is seen on a bract (Figs. 2e, h, S7g-h, S9d). Scales are attached on the periphery of the receptacle/ovary (Figs. 1h-i, S6a-b, S7a, g, S8i). The sepals are 1.7-3 mm long and 2.7-4.3 mm wide, with two lateral rib-free wings, with about four longitudinal ribs in the center, and attached to the receptacle rim with their whole bases (Figs. 1f, 2e, S6d-f, S7a, d-e, S8d-e, h-i, l). The epidermal cells are elongated, 44-156 $\mu\text{m} \times 33-54 \mu\text{m}$, with straight cell walls are seen in the middle region, while isodiametric epidermal cells 16-71 $\mu\text{m} \times 10-54 \mu\text{m}$ are seen in the lateral wings of the sepals (Figs. 4g, S9e-g, S10h-k). The petals are 3.1-6.6 mm long, 1.9-5.4 mm wide, compressed to only about 11 μm thick, with two lateral rib-free wings, with a cuneate base and longitudinal ribs in the center, inserted inside the sepals and on the rim of the receptacle (Figs. 1c-f, h-j, 2a, e, 3a, 4a, S6a-b, d-f, S7a-b, d, f-g, S8f-i, k, S10a-b, d-e). The ribs are approximately 0.12 mm wide, forking only basally, with elongated epidermal cells with straight cell walls, 32-144 $\mu\text{m} \times 17-30 \mu\text{m}$ on the abaxial and 19-72 $\mu\text{m} \times 13-29 \mu\text{m}$ on the adaxial (Figs. 4a-f, S9a-b). The lateral wings are free of ribs, and each is approximately 1.2 mm wide, with more or less isodiametric epidermal cells 23-64 $\mu\text{m} \times 18-37 \mu\text{m}$ (Figs. 4a, e, S10g). A possibly immature stoma is seen on one of the petals (Fig. S9c). A possible stamen is at least 1.1 mm long and 0.8 mm wide, with a stalk (equivalent to filament) at

An Unexpected Flower from the Jurassic of China

least 0.23 mm long and 43–76 μm in diameter (Figs. 4i–j). Four pollen sacs terminate the stalk, each 0.53 mm long and 0.27 mm wide (Figs. 4i–j). Possible *in situ* pollen grain is about 30 x 20 μm , psilate and possibly monocolpate (Figs. 4k–l, S6j). The receptacle is cup-form, 3–4.8 mm in diameter and 2–4.5 mm high, surrounded by a 0.3 mm thick wall in the bottom and sides, and covered by an ovarian roof about 0.2 mm thick from the top (Figs. 1h–i, 2a, e–h, 3a–b, f, S8d, f–g). The ovarian roof is horizontal, with smooth integral outer and inner surfaces, 0.14–0.22 mm thick, with a style vertically inserted on its center (Figs. 2a–c, e–g, S7c). The style is up to 1 mm in diameter, with lateral branches adding 2.6–4.4 mm width to the style (Figs. 1h–i, 2a–d, 3a, j–k, S6a–c, S8i–j). Each ovary contains two or more ovules that are 0.65–3 mm x 0.5–1.7 mm, elongated or oval-shaped, hanging on a 0.08–0.27 mm wide funiculus inserted on the inner wall of the receptacle/ovary (Figs. 1f, 2i, 3d–i, S5e, S8a–e). A micropyle-like depression 0.1–0.19 x 0.19–0.25 mm is seen on an ovule (Figs. 2i, S5e, S8a).

Holotype: PB22222 (Figs. 1a, 1c–d, 3f–g, S5e, S6c).

Isotypes: PB22221, PB22223–PB22229, PB22236, PB22238, PB22241–PB22243, PB22245–PB22247, PB22256–PB22260, PB22278–PB22282, PB22489.

Etymology: *dendrostyla*, for “tree-like” (*dendri-*) and “style” (*-stylus*) in Latin.

Figure 2 The flowers and their internal details. Bar = 1 mm except otherwise annotated.

A. A flower carefully degaged to expose the details of the gynoecium. Note the petals (p) and a style (arrow) in the center. PB22282. **B.** Detailed view of the style in Fig. 2a, showing its connection (arrows) to the ovarian roof (fr). Bar = 0.5 mm. **C.** Distal portion of the same style as in Fig. 2b, showing its dendroid form with lateral branches (arrows). Bar = 0.5 mm. **D.** Micro-CL slice 1169 showing a sepal/petal (black arrow) and branches (white arrows) of the style, embedded in sediments, of flower 4 in Fig. S5e. PB22222a. **E.** Side view of an organically-preserved flower with sepals (s) and petals (p). Note the dark organic material in the ovary (o) and some sepals. The foreground portion of the receptacle has been removed to show the internal details in Figs. 2f–h. PB22281. **F.** Detailed view of the receptacle/ovary in Fig. 2e. Note the ovarian roof (fr) preventing the outside (above) sediment (yellow color) from entering the ovarian locule. Bar = 0.2 mm. **G.** Detailed view of the solid organically-preserved ovarian roof (fr) with integral outer (upper arrow) and inner (lower arrow) surfaces. Bar = 0.1 mm. **H.** Bottom portion of the flower in Fig. 2e, showing subtending bracts (br, arrows). Bar = 0.5 mm. **I.** An elongated ovule with a micropyle-like depression (arrow) inside the ovary of Flower 9 in Fig. S5e. The inset shows the details of the micropyle-like depression. Bar = 0.5 mm, and inset bar = 0.1 mm.

Discussions

Several gymnosperm groups, including Caytoniales, Corystospermales, Ginkgoales, Czekanowskiales, Iraniales, Pentoxiales, Bennettitales, Coniferales, and Gnetales, flourished during the Mesozoic. However, these taxa have been well-studied and understood. Knowledge of these plants indicates clearly that *Nanjinganthus* distinguishes itself from all known gymnosperms, fossil and extant, by its probable bisexuality and with enclosed ovules in invaginated receptacle (see **Supporting Materials and Table 1**). The enclosed ovules makes it out of the question whether *Nanjinganthus* stands for another extinct gymnosperm, just as what happened to Caytoniales (Thomas 1925; Harris 1940; Barbacka and Boka 2000).

Bar = 20 μ m. **L.** Possibly monocolpate psilate pollen grain with a colpus (between arrows). Bar = 5 μ m.

Although multiple characters have been suggested to identify fossil angiosperms (Herendeen *et al.* 2017), angio-ovuly before pollination is the only character that guarantees an angiospermous affinity (Tomlinson and Takaso 2002; Wang 2010). This criterion has been repeatedly applied to identify fossil angiosperms (i.e. *Archaeofructus* (Sun *et al.* 1998)), because, at least initially, no other features (stamen, venation, pollen grains) were available to support its angiospermous affinity. In our material an integral ovarian roof has no any opening (Figs. 1h-i, 2e-g, 3a-b,f, S7c, and S8c,f-h). In some specimens this ovarian roof blocked the sediment from entering the ovarian locule (Figs. 2f-g). This suggests a full enclosure of ovules, confirming the angiospermous affinity for *Nanjinganthus*.

The radial arrangement of two whorls of foliar parts (sepals and petals) in *Nanjinganthus* is very similar to those of flowers in extant angiosperms (Figs. S11a-b). A closed ovary, 4-parted anther, probably bisexual reproductive organ, and

low number of ovules/seeds seen in *Nanjinganthus* (a character combination never seen in any known gymnosperm) emphasizes that *Nanjinganthus* cannot be interpreted as a gymnosperm. Furthermore, *Nanjinganthus* satisfies all thirteen definitions of flowers advanced by various authors (Bateman *et al.* 2006). These features reinforce the angiospermous affinity of *Nanjinganthus* (Fig. 5).

There have been several suggested models of ancestral angiosperms (Arber and Parkin 1907; Cronquist 1988; Endress and Doyle 2015; Sauquet *et al.* 2017). These models were drawn more or less after the assumed basalmost living angiosperms, *Magnolia* or *Amborella*. The common features of these model plants include apocarpous, superior ovary, lack of obvious style, etc. However, none of these features are seen in *Nanjinganthus*. Instead, an inferior ovary is clearly seen in *Nanjinganthus*, a feature unexpected by most theories of angiosperm evolution. This discrepancy suggests EITHER that inferences based on living plants have limited capability of “predicting” past history, OR that angiosperms originated polyphyletically and each lineage has followed a different evolution route, OR that angiosperms have a history longer than the Cretaceous, OR a combination of these. Whatever the implications are, the dominant theories of angiosperm evolution apparently do not reflect the botanical reality.

Most *Nanjinganthus* specimens are concentrated to a limited number of bedding surfaces, and up to 82 individuals are preserved on a single slab (Figs. 1a-b, S5a-g), suggesting that *Nanjinganthus* may have flourished and dominated a certain niche. The concentrated preservation of delicate flowers is more likely a result of autochthonous preservation, suggesting a habitat very close to water for *Nanjinganthus*.

Various studies including palaeobotany of the South Xiangshan Formation in the last century (Hsieh 1928; Li *et al.* 1935; Sze and Chow 1962; Zhou and Li 1980; Cao 1982; Wang *et al.* 1982; Huang 1983; Ju 1987; Huang 1988; Cao 1998; 2000) and our palynological analysis and U/Pb dating (Figs. S1b, S1f-g; Table S2; (Santos *et al.* in progress)) suggest a latest Early Jurassic age for *Nanjinganthus*. Together with the “unexpectedly” great diversity of angiosperms in the Early Cretaceous (Sun *et al.* 1998; Sun *et al.* 2001; Sun *et al.* 2002; Leng and Friis 2003; Ji *et al.* 2004; Leng and Friis 2006; Wang and Zheng 2009; Wang and Han 2011; Wang and Zheng 2012; Han *et al.* 2013; Wang 2015; Han *et al.* 2017), pollen grains indistinguishable from angiosperms in the Triassic (Hochuli and Feist-Burkhardt 2004; Hochuli and Feist-Burkhardt 2013), a bisexual flower from the Jurassic (Liu and Wang 2016), and an herbaceous angiosperm from the Middle Jurassic (Han *et al.* 2016), *Nanjinganthus* with over 200 specimens is an overwhelming evidence for a pre-Cretaceous origin of angiosperms, fully refuting the recently published self-conflicting review on early angiosperms (Herendeen *et al.* 2017) that does not reflect the true history of angiosperms (Wang 2017).

The systematic position of *Nanjinganthus* is apparently open to further investigation, although it demonstrates certain resemblance to Pentapetalae *sensu* (Judd *et al.* 2016). We cannot determine whether *Nanjinganthus* stands for a Jurassic stem group of angiosperms that started their radiation in the Cretaceous or a lateral branch leading to dead end of evolution. It is premature to determine its phylogenetic position before more information of contemporaneous plants is available, although we welcome other phylogeneticists to evaluate *Nanjinganthus* in their own ways and perspective.

Conclusion

The recognition of *Nanjinganthus* is based on at least 284 individual flowers from the Early Jurassic that are preserved in various states and orientations. The enclosed ovules suggest an angiospermous affinity for *Nanjinganthus*. The discovery of *Nanjinganthus* will trigger a re-thinking on the origin and early history of angiosperms and call for modifications to the current theories of angiosperm evolution.
