Role of regulatory extension on CFTR stability.

Abstract

Background and Purpose: Cystic Fibrosis (CF) is caused by mutations in the CF Transmembrane conductance Regulator (CFTR), the only ABC transporter functioning as a channel. Unique to CFTR are two highly conformationally dynamic regions: the regulatory extension (RE) and regulatory insertion (RI). Removal of the latter rescues the trafficking defect of CFTR with F508del, the most common CF-causing mutation.

We aimed here to assess the impact of RE removal (alone or with RI or genetic revertants) on F508del-CFTR traffic and how CFTR modulator drugs corrector VX-809/lumacaftor and potentiator VX-770/ivacaftor rescue these combined variants so as to gain insight into the mechanism of action (MoA) of these drugs.

Experimental Approach. We generated ΔRE and ΔRI CFTR variants (with and without genetic revertants) by site-directed mutagenesis and used them to stably transfect BHK cell lines. We studied CFTR expression and stability by Western blotting and pulse-chase respectively, plasma membrane levels by cell surface biotinylation and channel activity by the iodide efflux technique.

Key Results. Our data demonstrate that ΔRI significantly enhanced rescue of F508del-CFTR by VX-809. Thus, while the presence of the regulatory insertion seems to be precluding full rescue of F508del-CFTR processing by VX-809, this region appears essential to rescue its function by VX-770, thus suggesting some contradictory role in rescue of F508del-CFTR by these two modulators. Nevertheless, this negative impact of RI removal on VX-770-stimulated currents on F508del-CFTR can be compensated by deletion of the regulatory extension which also leads to the stabilization of this mutant. We thus propose that, despite both these regions being conformationally active, RI precludes F508del-CFTR processing while RE affects mostly its stability and channel opening.
Role of regulatory extension on CFTR stability.

Introduction

Cystic Fibrosis (CF), a life-threatening recessive disorder affecting ~80,000 individuals worldwide, is caused by mutations in the gene encoding the CF transmembrane conductance regulator (CFTR) protein present at the apical membrane of epithelial cells. This is the only member of the ATP-binding cassette (ABC) transporter family, functioning as a channel, actually a cAMP-dependent chloride (Cl)/bicarbonate (HCO₃⁻) channel. It consists of two membrane-spanning domains (MSD1/2), two nucleotide binding domains (NBD1/2) and a cytoplasmic regulatory domain (RD), which is unique to CFTR. The MSDs are linked via intra- and extra-cellular loops (ICLs, ECLs, respectively). ATP binding promoting NBD1:NBD2 dimerization and subsequent phosphorylation of RD at multiple sites lead to channel gating. The NBD1:NBD2 and ICL4:NBD1 interfaces were shown to represent critical folding conformational sites important for the gating and maturation of the CFTR protein.

Although >2,000 CFTR gene mutations were reported (http://www.genet.sickkids.on.ca/cftr/app), one mutation F508del occurs in 85% of CF patients. This NBD1 mutant fails to traffic to the plasma membrane (PM) due to protein misfolding and retention by the endoplasmic reticulum quality control (ERQC) that targets it to premature proteasomal degradation. F508del-CFTR folding is a complex and inefficient process but it can be rescued, at least partially, by several treatments. These include low temperature incubation, genetic revertants or pharmacological agents, like "corrector" VX-809 (lumacaftor), one of the first CFTR modulator drugs to receive FDA-approved in combination with potentiator VX-770/ivacaftor. Determining the additive/synergistic rescue of F508del-CFTR by small molecules correctors together with other rescuing agents/revertants is very valuable to determine the mechanism of action (MoA) of these CFTR modulators.

Comparative studies of CFTR with other ABC transporters are very powerful to understand the uniqueness of some of its regions, their influence on CFTR maturation and function as well as how they affect distinctive binding of CFTR to modulator drugs. Two such unique regions are present in NBD1 of CFTR, which are absent in NBDs of other ABC transporters (Fig.S1) - the regulatory extension (RE) and regulatory insertion (RI). Both regions were described as highly conformationally dynamic following PKA phosphorylation at certain references. Importantly, removal the 32-amino acid RI (ΔRI) was reported to rescue traffic of F508del-CFTR.

Our first goal here was to assess the impact of removing the 30-amino acid RE (ΔRE) alone or jointly with ΔRI on the traffic of F508del-CFTR. Secondly, we aimed to evaluate how RE and or RI removal from F508del-CFTR influences the rescue of this mutant by genetic revertants. Our third and final

Role of regulatory extension on CFTR stability.

goal was to determine how the traffic and function of these combined variants of F508del-CFTR (ΔRE, ΔRI plus genetic revertants) are rescued by CFTR modulator drugs VX-809 (corrector) and VX-770 (potentiator) to gain further insight into their MoA.

Our data show that although F508del-CFTR without RE did not traffic to the PM, it showed a dramatic stabilization of its immature form (evidencing a turnover rate ~3 x lower than that of wt-CFTR, being the turnover of F508del-CFTR itself is 2x faster vs. wt-CFTR). Results also show that, while ΔRI further increased processing of F508del-CFTR with revertants to almost wt-CFTR levels, RE removal completely abolished their processing, thus highlighting the different impact of the two dynamic regions on revertant-rescued F508del-CFTR. Most strikingly, although VX-809 rescued ΔRI-F508del-CFTR and ΔRE-ΔRI-F508del-CFTR processing to wt-CFTR levels, nevertheless to achieve maximal function of F508del-CFTR, removal of just RI was insufficient, as both RI and RE had to be absent from F508del-CFTR. These data indicate that removal of these two regions has a positive effect on the rescuing efficacy of F508del-CFTR by CFTR modulators.
Role of regulatory extension on CFTR stability.

Methods

CFTR variants, cells and culture conditions

Several CFTR deletion variants were produced by site-directed mutagenesis corresponding to the removal of residues: ΔRIl – 404Gly-Leu345; ΔRIk – 412Ala-Leu428; ΔREL – 547Cys-Ser557; ΔRES – 654Ser-Gly673; ΔH9 – 637Gln-Gly646; ΔRELΔH9 – 637Gln-Ser678; ΔRIkΔRES – both 412Ala-Leu428 and 654Ser-Gly673; and ΔRIlΔREΔS – 405Gly-Leu435 and 654Ser-Gly673. All the constructs were produced using full length wt-CFTR and F508del-CFTR.

BHK cells lines expressing ΔRIlΔ, ΔRIkΔF508delΔ, ΔRIkΔG550EΔ, ΔRIlΔG550EΔF508delΔ, ΔRIlΔR1070WΔ, ΔRIkΔR1070WΔF508delΔ, ΔRIkΔF508delΔ, ΔRIkΔG550EΔ, ΔRIlΔG550EΔF508delΔ, ΔRIlΔR1070WΔ, ΔRIlΔR1070WΔF508delΔ, ΔREΔΔ, ΔREΔΔF508delΔ, ΔRIkΔΔG550EΔ, ΔREΔΔG550EΔF508delΔ, ΔREΔΔR1070WΔ, ΔREΔΔR1070WΔF508delΔ, ΔREΔΔF508delΔ, ΔRIkΔΔΔΔF508delΔ, ΔRIlΔΔΔΔF508delΔ, ΔRIlΔΔΔΔF508delΔ, ΔRIlΔΔΔΔF508delΔ, ΔH9Δ, ΔH9ΔF508delΔ, ΔREΔΔH9ΔF508delΔCFTR were produced and cultured as previously described 11. Cells were cultured in DMEM/F-12 medium containing 5% (v/v) FBS and 500µM of methotrexate. For some experiments, cells were incubated with 3µM VX-809 or with the equivalent concentration of DMSO (Control) for 48h at 37°C.

Western blot

To study the effect of removal of regulatory extension (RE) and or regulatory insertion (RI) in combination with genetic revertants and VX-809, cells were incubated for 48h at 37°C with 3µM VX-809. After incubation, cells were lysed and extracts analysed by Western blot (WB) using the anti-CFTR antibody (Ab) 596 or anti-calnexin Ab as a loading control. Score corresponds to the percentage of band C to total CFTR (bands B+C) as normalized to the same ratio in samples from wt-CFTR expressing cells. Blot images were acquired using BioRad ChemiDoc XRC+ imaging system and band intensities were measured using Image Lab analysis software.

Pulse-chase and immunoprecipitation

BHK cells lines stably expressing CFTR variants were starved for 30 min in methionine-free α-modified Eagle’s medium or minimal essential medium and then pulsed for 30min in the same medium supplemented with 100µCi/ml [35S]methionine. After chasing for 0, 0.5, 1, 1.5, 2 and 3h in α-modified Eagle’s medium with 8% (v/v) fetal bovine serum and 1mM non-radioactive methionine, cells were lysed in 1ml of RIPA buffer [1% (w/v) deoxycholic acid, 1% (v/v) Triton X-100, 0.1% (w/v) SDS, 50mM Tris, pH7.4, and 150mM NaCl]. The immunoprecipitation (IP) was carried out using the
anti-CFTR antibody in independent experiments and Protein G–agarose or Protein A–Sepharose beads. Immunoprecipitated proteins were eluted from the beads with sample buffer for 1h at room temperature and then electrophoretically separated on 7% (w/v) polyacrylamide gels. Gels were pre-fixed in methanol/acetic acid (30:10, v/v), washed in water and, for fluorography, soaked in 1M sodium salicylate for 60 min. After drying at 80°C for 2h, gels were exposed to X-ray films and further analysed and quantified by densitometry.

Iodide efflux

CFTR-mediated iodide effluxes were measured at room temperature using the cAMP agonist forskolin (Fsk 10µM) and the CFTR potentiator genistein (Gen, 50µM) or VX-770 (10µM) and Gen (50µM).

Biochemical determination of the plasma membrane levels of CFTR

To determine plasma membrane levels of CFTR protein, we performed cell surface biotinylation in BHK cells cultured on permeable growth supports or tissue culture plates using cell membrane impermeable EZ-Link™ Sulfo-NHS-SS-Biotin, followed by cell lysis in buffer containing 25 mM HEPES, pH 8.0, 1% (v/v) Triton, 10% glycerol (v/v), and Complete Protease Inhibitor Mixture, as described previously 23,24. Biotinylated proteins were isolated by streptavidin-agarose beads, eluted into SDS-sample buffer, and separated by 7.5% (w/v) SDS-PAGE.

Multiple sequence alignment

Sequences for NBD domains of ABC transporters were obtained from Uniprot 25 (human and mouse CFTR) or the PDB 26 (1B0U, 1L2T, 1G29, 1G6H, 1JJ7). Alignments were performed with Jalview 27 using the T-Coffee 28 algorithm using the default parameters.

Data and Statistical analyses

The data and statistical analyses used in this study comply with the recommendations on experimental design and data analysis in pharmacology (Curtis et al., 2015). Quantitative results are shown as mean±SEM of n observations. To compare two sets of data, Student t-test was used and differences considered to be significant for p-values ≤ 0.05. In Western blotting (Figures 1-3), pulse chase (Figures 4, S3); cell surface biotinylation (Figure 4) and in iodide efflux studies (Table 1, Figure
Role of regulatory extension on CFTR stability.

5, S4 and S5), n represents the number of experiments performed with distinct cell cultures on different days, being thus biological replicates.

Reagents

All reagents used here were of the highest purity grade available. Forskolin and genistein were from Sigma-Aldrich (St. Louis, MI, USA); VX-809 and VX-770 were acquired from Selleck Chemicals (Houston, TX, USA).

CFTR was detected with the mouse anti-CFTR monoclonal 596Ab, which recognizes a region of NBD2 (1204 – 1211) from CFFT-Cystic Fibrosis Foundation Therapeutics CFF Therapeutics (Cui et al., 2007) and calnexin with rabbit polyclonal anti-calnexin Ab SPA-860, from Stressgen Biotechnologies Corporation (Victoria, BC, Canada).

Other specific reagents included: X-ray films (Kodak, supplied by Sigma-Aldrich); Complete Protease Inhibitor Mixture from Roche Applied Science (Penzberg, Germany); EZ-Link™ Sulfo-NHS-SS-Biotin from Pierce Chemical Company (Rockford, IL, USA).
Role of regulatory extension on CFTR stability.

RESULTS

Removal of short regulatory extension (RE₃) alone or with regulatory insertion (RI) has no impact on F508del-CFTR processing

The impact of deleting RE₃ – short RE (Δ⁶⁵⁴Ser-Gly⁶⁷³, Figure S1) was first assessed, either alone or together with RI in its short and long variants (ΔRI₅, ΔRI₆), on the in vivo processing of wt- and F508del-CFTR by Western blot (WB) of BHK cells stably expressing such variants (Fig.1A,D,E; Table1). Removal of RE₃ had no impact on processing of either F508del-CFTR or wt-CFTR (Fig.1A, lanes 5,10; Table1), despite that the immature form of ΔRE₃:F508del-CFTR appeared consistently at increased levels vs. those of F508del-CFTR (Fig.1A, lanes 5,2).

Removal of RE₃ together with RI₅ – long RI (Δ⁴⁰⁴Gly-Leu⁴²⁵, Figure S1) led to a maturation increase of F508del-CFTR from 3±2% to 71±3% (vs wt-CFTR levels), similarly to what had been previously reported by Alexandrov et al for ΔRI₅ alone ¹³. In contrast, removal of RI₅ – short RI (Δ⁴¹²Ala-Leu⁴²⁸, Figure S1) had no impact on ΔRE₃:F508del-CFTR processing (Fig.1A, lanes 6,7; Fig.1E; Table1). So in summary, removal of RE₃ jointly with RI₅ or RI₆ had no effect on F508del-CFTR processing.

Interestingly, when RE₃ and RI₅, were jointly removed from wt-CFTR, its processing was significantly reduced to 54±9%, while ΔRE₃ jointly with ΔRI₅ caused no impact (Fig.1A, lanes11,12, respectively; Fig.1D; Table1). Again, these data were equivalent to removal of ΔRI₅ or ΔRI₆ alone on wt-CFTR processing (Fig.1A, lanes8,9; Fig.1E; Table1).
Role of regulatory extension on CFTR stability.

The differential effect caused by removal of RIₜ vs RIₜ on F508del- and wt-CFTR emphasize the importance of those 8 N-term (⁴⁰⁴Gly-Ala⁴₁²) and 7 C-term (Leu⁴₂₈-Leu⁴₃⁵) amino acid residues that differ between those 2 RI regions for the folding and processing of CFTR.

Simultaneous removal of long regulatory extension (REₜ) and helix H₉ significantly reduces wt-CFTR processing but increases levels of F508del-CFTR immature form

Next, we assessed the impact of removing the long version of RE – REₜ (Δ⁶⁴⁷Cys-Ser⁶⁷₈, Fig.2), which significantly decreased wt-CFTR processing to 88±5% (Fig.2A, lane 3; Fig.2C) but had no impact on F508del-CFTR (Fig.2A, lane4; Fig.2C). As helix H₉ (Δ⁶⁷⁷Gln-Gly⁶⁴₆, Figure S1) can be considered to be part of this longer RE region since it interacts with RE (Figure S2), we also tested the effect of removing helix H₉ jointly with ΔREₜ. Deletion of both H₉ (ΔH₉) and REₜ further decreased the residual processing of ΔREₜ-F508del-CFTR from 9±2 to 0±0% and in fact the same happened for ΔH₉ alone (Fig.2a, lanes 8,6, respectively). Curiously, however, levels of immature F508del-CFTR were significantly increased when both REₜ and H₉ were removed (Fig.2a, lane8), similarly to ΔREₜ-F508del-CFTR (Fig.1A) and in contrast to ΔREₜ-F508del-CFTR.

For wt-CFTR, ΔREₜ-ΔH₉ also led to a decrease in processing (55±3%), which was more pronounced than for ΔREₜ alone, but interestingly removal of H₉ helix alone only reduced processing to 72±4% (Fig.2A, lanes 7,5, respectively).

ΔRIₜₜ, but not ΔREₜₜ, abolishes the plasma membrane rescue of F508del-CFTR by revertants

In order to test whether the stabilized immature form of ΔREₜ-F508del-CFTR could be rescued to mature form, we next tested the effects of removing the REₜ from F508del-CFTR with R1070W and G550E revertants. Indeed, both the R1070W and G550E revertants rescued ΔREₜ-F508del-CFTR to 33±7% and 37±5%, respectively (Fig.1C, lanes 6,10; Table1).

However, removal of RIₜ from F508del-CFTR with R1070W and G550E revertants, virtually abolished the rescue of F508del-CFTR by both revertants (Fig.1C, lanes 4,8; Table1). Moreover, processing of ΔRIₜ-F508del-CFTR was further increased by either R1070W or G550E up to 96±2% and 92±4%, respectively (Fig.1C, lanes 5,9; Table1). Alone, R1070W and G550E rescued F508del-CFTR from 8±1% to 34±3% and 42±4% respectively (Fig.1C, lanes 3,7; Table1), as we previously reported.

Interestingly, the impaired processing of ΔRIₜ-wt-CFTR (44±2%) was significantly rescued by G550E (to 82±3%), but curiously it was further reduced by R1070W (to 11%) i.e., close to levels of F508del-CFTR processing (Fig.1B, lanes8,4; Table1). Of note that R1070W alone also reduced wt-CFTR
Role of regulatory extension on CFTR stability.

processing to 69±7%, but this reduction could be compensated by the removal of RIL (92±2%) (Fig.1B, lanes 3,5; Table1), while G550E alone caused no effect on wt-CFTR processing (Fig.1B, lane7).

ΔRIL synergises with VX-809, but not with revertants to rescue ΔRE5-F508del-CFTR processing

To further test how the stabilized immature form of ΔRE5-F508del-CFTR could be pharmacologically rescued, we then assessed the impact of corrector VX-809 (which per se promotes maturation of the F508del-CFTR) on the processing of this and of the other variants, to obtain structural insight on the effects of this novel drug. Although ΔRE5-F508del-CFTR could not be rescued by VX-809, data show that this small molecule was able to rescue ΔRIL-ΔRE5-F508del-CFTR (from 7±2% to 20±4%) and further increased processing of ΔRIL-ΔRE5-F508del-CFTR to wt-CFTR levels (from 71±3% to 96±2%) (Fig.3A, lanes 6,7; Fig.3E; Table1). These data suggest a strong synergistic effect between VX-809 and ΔRIL (and with ΔRILs, albeit to a lesser extent) to rescue ΔRE5-F508del-CFTR processing. This is particularly interesting because VX-809 did not rescue processing of the ΔRE5-, nor ΔRILs-F508del-CFTR variants (Fig.3A, lanes 5,3; Table1) while it recovered the processing of ΔRILs-F508del-CFTR to wt-CFTR levels (Fig.3A, lane4; Table1). Notably, VX-809 was able to almost completely revert processing impairment of ΔRILs-wt-CFTR and ΔRILs-ΔRE5-CFTR (from 44±2% and 54±9%) to 90±3% and 93±3%, respectively (Fig.3A, lanes8,11; Fig.3D; Table1).

Strikingly, VX-809 had no effect on processing of ΔRE5-F508del-CFTR with R1070W or G550E (Fig.3C, lanes 6,10; Fig.3E; Table1), while it further rescued processing of F508del-CFTR variants with R1070W or G550E alone to 46±4% and 73±6%, respectively (Fig.3C, lanes 3,7; Fig.3E; Table 1), as reported 5. Similarly, VX-809 caused no significant further rescue on the processing of ΔRIL-F508del-CFTR with those revertants, but these variants already had processing levels close to those of wt-CFTR (Fig.3C, lanes 5, 9; Fig.3E; Table 1). Interestingly, the impaired processing of ΔRE5-R1070W-wt-CFTR (71±6%) was also reverted by VX-809 to 90±3% (Fig.3B, lane 6; Table 1).

Corrector VX-809 failed to rescue any of the ΔRE5-, ΔH9- and ΔRE5-ΔH9-F508del-CFTR variants (Fig.2B, C), while significantly increasing the processing of the ΔRE5-ΔH9-wt-CFTR from 55±3% to 69±3% (Fig.2B, lane 7; Fig.2C).

ΔRIL-ΔRE5-F508del-CFTR levels at the plasma membrane are equivalent to those of wt-CFTR

#
Role of regulatory extension on CFTR stability.

To determine the fraction of the above CFTR variants that localize to the PM, we used quantitative cell surface biotinylation. These data showed that PM levels of ΔRI\textsubscript{L}-ΔRE\textsubscript{S}-F508del-CFTR were equivalent to those of wt-CFTR, while those of ΔRI\textsubscript{L}-F508del-CFTR were significantly lower (Fig.4A, lanes 5, 4; Fig.4B). Data also confirmed that ΔRE\textsubscript{S} did not induce appearance of F508del-CFTR at the cell surface (data not shown). Corrector VX-809 further increased the PM expression of ΔRI\textsubscript{L}-ΔRE\textsubscript{S}-F508del-CFTR to levels that are significantly higher than those of wt-CFTR (Fig.4A, lanes 2, 9, Fig.4B). This compound also significantly increased PM levels of ΔRI\textsubscript{L}-F508del-CFTR to similar levels of wt-CFTR (Fig.4A, lanes 2, 8; Fig.4B).

Given the very significant stabilization of immature ΔRE\textsubscript{S}-F508del-CFTR (Fig.1A), next, we determined how removal of ΔRE\textsubscript{S} affected the processing efficiency and the turnover of the F508del- and ΔRI\textsubscript{L}-F508del-CFTR variants. To this end, we performed pulse-chase experiments (Fig.4C, D) and indeed our results revealed that ΔRE\textsubscript{S} very significantly stabilized immature F508del-CFTR not just relatively to F508del-CFTR but to levels even significantly higher than those of wt-CFTR (Fig.4C, D). Interestingly, this stabilizing effect was no longer significant for ΔRI\textsubscript{L}-ΔRE\textsubscript{S}-F508del-CFTR nor for ΔRI\textsubscript{L}-F508del-CFTR, the latter being equivalent to wt-CFTR (Fig.4C, D). Removal of RI\textsubscript{S} from F508del-CFTR did not stabilize its turnover (data not shown). As to removal of either RE\textsubscript{S} or RI\textsubscript{S} from wt-CFTR, it did not affect the processing efficiency or the turnover vs wt-CFTR (Figure S3).

**VX-809 jointly with RE and RI removal completely restored F508del-CFTR function as chloride channel**

To investigate the channel function of the ΔRE\textsubscript{S}- and ΔRI\textsubscript{L}-F508del-CFTR variants, we used the iodide efflux technique. Removal of RE\textsubscript{S} alone had no impact on F508del-CFTR function (Fig.5A; black dash line in Figure S4B) as expected from the lack of processed form for this variant (Fig.1A). However, when RE\textsubscript{S} and RI\textsubscript{L} were removed jointly from F508del-CFTR, functional levels reached 78±7% of wt-CFTR (Fig.5A, C; black dotted line in Figure S4B). As to removal of RI\textsubscript{L} alone from F508del-CFTR, it restored function to 92±7% of wt-CFTR (Fig.5A, C; black line in Figure S4B), as described \textsuperscript{11}. Also, the delay in peak response observed for F508del-CFTR (min=4) vs wt-CFTR (min=2), was partially corrected (to min=3) both by removal of RI\textsubscript{L} alone from F508del-CFTR or together with RE\textsubscript{S} (Fig.5C; Figure S4B, black line and dotted line).

Introduction of G550E and R1070W revertants into the ΔRI\textsubscript{L}-F508del-CFTR variant slightly but not significantly decreased its function from 92±7% to 71±8% and 76±8%, respectively (Fig.5A, C; black lines in Figure S4C, D), in parallel to the respective processing levels (Fig.1). In fact, these variants showed higher activity levels than the revertants containing RI\textsubscript{L} (29±3% and 56±6%, respectively).
Interestingly however, both G550E- and R1070W-ΔR1l-F508del-CFTR fully corrected (to min=2) the delay in peak response of F508del-CFTR, which was still partially present in ΔR1l- and ΔR1l-RE5-F508del-CFTR (min=3).

The effect of VX-809 (3µM, 48h at 37ºC) was also examined at functional level on the ΔRE5-, ΔR1l-ΔRE5- and ΔR1l-F508del-CFTR variants. Strikingly VX-809 caused an increase in ΔR1l-delta508del-CFTR function (84±8% of wt-CFTR) which was parallel to the observed increase in PM expression (Fig.4; Fig.5A, C; black dotted line in Figure S4F). Also, ΔRE5-ΔR1l-F508del-CFTR fully corrected (to min=2) the delay in peak response of F508del-CFTR which was still partially present in ΔR1l- and ΔR1l-ΔRE5-F508del-CFTR (min=3).

In contrast to the observed increase in processing, VX-809 caused no significant increase in the function of ΔR1l-F508del-CFTR and actually a slight, but not significant decrease was observed and there was still the same delay in peak response (Fig.5A, C; black line in Figure S4F).

A similar slight decrease in function was observed for VX-809 on the ΔR1l-R1070W-F508del-CFTR variant (Fig.5A, C; black line in Figure S4H), but the most striking result was observed for the significant decrease caused by VX-809 on function of ΔR1l-G550E-F508del from 76±8 to 41±3% (Fig.5A, C; black line in Figure S4G). Nevertheless both revertant variants of ΔR1l-F508del-CFTR showed no change in peak response which was still the same as wt-CFTR (min=2).

**VX-770-stimulated currents of CFTR variants are dramatically decreased by ΔR1l, but not by ΔR1l-ΔRE5**

Given the interesting and diverse results observed for the ΔRE5 and ΔR1l under VX-809, next we tested the effects of potentiator VX-770 (Ivacaftor), an approved drug for CF patients with gating mutations (Fig.5B) on these variants and in combination with VX-809, for F508del/F508del patents. Most strikingly, our data show that VX-770/Fsk significantly decreased the function of ΔR1l-F508del-CFTR vs potentiation by Gen/Fsk (Fig.5B, C) from 92±7% to 58±7% of wt-CFTR (Fig.5B, C; black line in Figure S4J). As ΔRE5-F508del-CFTR was not processed, we did not test the effect of VX-770 on this variant, but when the ΔRE5-ΔR1l-F508del-CFTR variant was assessed for its function after acute application of VX-770 with Fsk, an increase in function (to 87±3% of wt-CFTR) was observed vs its function under Gen/Fsk (78±7% of wt-CFTR) (Fig.5B, C; black dotted line in Figure S4J).

The most dramatic result, however, was observed for the ΔR1l-G550E-F508del-CFTR variant which under VX-770/Fsk only had 4±1% function of wt-CFTR, while under Gen/Fsk it had 76±8% (Fig.5B, C; black line in Figure S4K). For ΔR1l-R1070W-F508del-CFTR this decrease was not observed (Fig.5B, C;
black line in Figure S4L), and in fact this variant had a slightly higher function under VX-770 stimulation (72±4%) than ΔRI\textsubscript{L}-F508del-CFTR (58±7%) (Fig. S5B, C, black line in Figure S4H).

The delay in peak response of F508del- vs. wt-CFTR was not corrected for ΔRI\textsubscript{L}-F508del-CFTR (min=3), but it was corrected for ΔRI\textsubscript{L}-ΔRE\textsubscript{S}-F508del-CFTR (min=2) (black and dotted black lines in Figure S4J, respectively). Curiously, on the other hand ΔRI\textsubscript{L}-R1070W-F508del-CFTR showed the quickest peak response (at min=1), in contrast to either R1070W-F508del-CFTR or ΔRI\textsubscript{L}-F508del-CFTR, both at min=3.

Similarly, VX-770 also significantly decreased the function of ΔRI\textsubscript{L}-wt-CFTR from 127±15% under Gen to 57±6% (Figure S5).
Role of regulatory extension on CFTR stability.

Discussion

The main goal of this study was to understand how the removal of the regulatory extension (ΔRE) alone or with the regulatory insertion (ΔRI)- two highly conformationally dynamic regions - impacted on the rescue of F508del-CFTR processing and function by two compounds - VX-809 and VX-770 - which in combination were recently approved to clinically treat F508del-homozygous patients. Indeed, CFTR is the sole ABC that functions as a channel and thus, these highly dynamic RE and RI regions which are absent in other ABC transporters, may be of high relevance to understand how CFTR differs from other ABCs, namely in its function as a channel.

These regions RE and RI were originally suggested to be positioned to impede formation of the NBD1-NBD2 dimer required for channel gating. Indeed, both RI and RE were shown to be mobile elements in solution that bind transiently to the core of NBD in the β-sheet and α/β subdomains of NBD1. Similarly to what demonstrated for RI, it is plausible to posit that the dynamic flexibility of the RE may also result in exposure of hydrophobic surfaces thus contributing to the dynamic instability of NBD1 and thus contribute to the low folding efficiency of F508del-CFTR. The RE is a ~30-residue segment at NBD1 C-terminus, so-called because it goes beyond canonical ABC NBDs.

Although this region was absent from the solved CFTR-NBD1 crystal structure, it was described as a helix packing against NBD1 at the NBD1:NBD2 interface and NMR data showed it has significant conformational flexibility. Notwithstanding, there is some controversy regarding the RE boundaries. The RE (previously called H9c) was defined as Ala-Ser670, Asp-Ser670, or Ser-Gly673. According to the crystal structure (PDB code 2PZE), NBD1 extends only to 646Gly, where RD begins, so RE could be proposed to start at 647Cys, being thus considered as part of RD, a domain absent in other ABC transporters. As for the RI (previously called S1-S2 loop) its limits are also variable, being firstly described as a ~35-residue segment (405Phe436Leu) consisting of α-helices H1b and H1c (Fig.S1). Later, however, these limits were proposed to be Gly-Leu135 or Phe-Leu436.

Impact of RE and RI on CFTR processing and function

Our data shown here on CFTR variants depleted of different versions of the RE dynamic region demonstrate that unlike RI deletion, removal of short RE - ΔRE5 (Δ654Ser-Gly673) did not per se rescue F508del-CFTR processing. Nevertheless, ΔRE5 dramatically stabilized the immature form of F508del-CFTR (see Fig.6). In fact, our pulse-chase experiments show that the immature form of ΔRE5-F508del-CFTR exhibits a turnover rate which is ~2.7 fold lower than that of wt-CFTR. Of note, when Aleksandrov et al removed the dynamic region RI from F508del-CFTR they found a dramatic increase
Role of regulatory extension on CFTR stability.

in the channel thermostability, even augmented for higher temperatures \(^\text{13}\). Interestingly however, removal of the RE\(_5\) from \(\Delta R\_L\_F508\text{del-CFTR} (\Delta R\_L\_: \Delta^{404}\text{Gly-Leu}^{435})\) while not affect processing, it further reduced its function (from 92% to 78%).

The latter findings on function of \(\Delta R\_E\_5\)-wt-CFTR and \(\Delta R\_E\_5\Delta R\_L\_F508\text{del-CFTR}\) were somewhat surprising since the RE was previously described to impede putative NBD1:NBD2 dimerization that is required for channel gating \(^\text{21}\). Accordingly, an increase in CFTR activity would be expected upon \(\Delta R\_E\_5\) removal, which is actually the opposite of what we observe for wt-CFTR. Besides the fact that those authors studied a different RE version (\(\Delta^{639}\text{Asp-Ser}^{670}\)), this discrepancy could derive from structural constraints and lack of flexibility of the ‘single polypeptide’ protein that we used, vs their ‘split’ CFTR channels (2 ‘halves’ of 633 and 668 aa) for which channel function was indistinguishable from wt-CFTR \(^\text{21}\). Moreover, since RD phosphorylation is required for channel gating \(^\text{29,30}\), the reduced function of \(\Delta R\_E\_5\)-wt-CFTR may also result from absence of \(\Delta^{660}\text{Ser}\) and \(\Delta^{670}\text{Ser}\) \(^\text{19,20}\). Although the RD contains more than ten PKA phospho-sites and no individual one is essential, phosphorylation of increasing numbers of sites enables progressively greater channel activity \(^\text{31}\).

Removal of a longer RE version (\(\Delta R\_E\_2\: \Delta^{467}\text{Cys-Ser}^{678}\)) was without effect on F508del-CFTR processing and significantly reduced that of wt-CFTR to 88%. Such differential impact on wt- and F508del-CFTR is consistent with the conformational heterogeneity between these two proteins lacking both RI and RE \(^\text{32}\).

Removal of RI short version, \(RI\_L\_ (\Delta^{412}\text{Ala-Leu}^{428})\) significantly reduced wt-CFTR processing to less than half of its normal levels, while not rescuing F508del-CFTR processing, thus being essential for CFTR proper folding. This is in contrast to removal of long RI (\(RI\_L\_\) which led to 78% processing F508del-CFTR, as reported \(^\text{13}\) but without impact on wt-CFTR. These data indicate that those 8/ 7 amino acid residues at the N-term/ C-term of RI\(_L\_\) (and absent in RI\(_L\_\)) impair the folding efficiency and processing of both wt- and F508del-CFTR.

The recently published cryo-EM structure of human CFTR \(^\text{33}\) indicates that these regions are structurally disordered. Consistently, the RI loop in NBD1 is described in the of zebrafish CFTR cryo-structure to contribute to the amorphous density that is observed between NBD1 and the elbow helix of TMD2 \(^\text{34}\). From a structural point of view, models of the full-length CFTR protein suggest that the two regions (RI and RE) behave differently. The distances between the extremities of the deleted parts are indeed different (\(\Delta R\_I\_L\_ = 18\text{Å}, \Delta R\_I\_ = 10\text{Å} \text{versus } \Delta R\_E\_L\_ = 27\text{Å}, \Delta R\_E\_ = 30\text{Å}\)). The longer distances observed for \(\Delta R\_E\_\) imply a substantial reorganization of the C-terminal parts of NBD1 and NBD2, which precludes a clear understanding of what might happen upon these deletions. In contrast, the lower distances observed for \(\Delta R\_I\_\) (near a possible minimum of 6Å) allows a better simulation of the
Role of regulatory extension on CFTR stability.

possible structural behaviour of these constructs. Indeed, preliminary molecular dynamics simulations of the ΔRI₇-F508del-CFTR suggested that in this case, part of the RD is reorganized and partially takes space left by the ΔRI deletion, thereby substituting it for tight contacts with NBD2. Meanwhile, following a probable allosteric effect, contact of NBD1-F508 with ICL4 residue L1077 (a likely essential contact for channel opening), is nearly completely restored by I507. Such a feature is not observed in the F508del-CFTR model (B. Hoffmann, I. Callebaut and J.-P. Mornon, personal communication).

Effect of VX-809 on F508del-CFTR variants lacking RE and RI

As for rescue of CFTR variants lacking RE and RI by CFTR modulators, VX-809 restored the processing of both ΔRE₅-ΔRI₇- and ΔRI₇-F508del-CFTR variants equally well and to wt-CFTR levels (from 71-78% to 92-96%). These data suggest a strong synergistic effect between VX-809 and ΔRI₇ to rescue ΔRE₅-F508del-CFTR processing and thus some possible interference of the regulatory insertion with VX-809 binding to F508del-CFTR (see Fig.6). Indeed, although previous studies suggested putative binding of VX-809 to NBD1:MSD2 (ICL4) interface (see Fig.6), they also suggested scope for further F508del-CFTR correction at distinct conformational sites, so data shown here suggest that VX-809 may also bind to the regulatory insertion.

Interestingly, the processing defect of ΔRI₅-wt-CFTR (but not of ΔRI₇-F508del-CFTR) was rescuable by VX-809 to 90%, indicating that the amino acid stretches of the RI₇ that remain present in RI₅ do not affect the rescue of ΔRI₅-wt-CFTR but preclude rescue of F508del-CFTR by VX-809.

We also tested here the impact of removing helix 9 (H9) which precedes the RE (G535-Gln-Gly646), just after H8 (P60-Phe-Leu634), both helices proposed to interact with the NBD1:NBD2 heterodimer interface by folding onto the NBD1 β-subdomain as well as to bind ICL4 near Phe508. When H9 is present, ΔRE₅-wt-CFTR processing appears to be favoured by VX-809, suggesting some synergy of this small molecule with H9 helix to correct the conformational defect(s) caused by ΔRE₅ on wt-CFTR. These data are in contrast to ΔH₉-F508del-CFTR which exhibits 0% processing with or without ΔRE₅ and no rescue by VX-809.

Very strikingly, and in contrast to its effect on processing, was the effect of ΔRI₇ on the VX-770 stimulated currents which were decreased by almost half vs those stimulated by Gen/Fsk (92% to 58%). These data seem to indicate that the absence of the regulatory insertion could impair (and its presence favour) binding of VX-770 to CFTR (see Fig.6). Surprisingly, the removal of RE₅ from ΔRI₇-F508del-CFTR could correct this defect and restore the maximal function by VX-770 (see Fig.6). Indeed, under VX-770, ΔRE₅-ΔRI₇-F508del-CFTR exhibited significantly higher activity (87%) than ΔRI₇-
Role of regulatory extension on CFTR stability.

F508del-CFTR (58%). In contrast, removal of RE5 from wt-CFTR significantly reduced its function vs that of wt-CFTR (down to 70%) but had no effect on processing.

Impact of F508del-revertants on CFTR variants lacking RE and RI

Another goal of the present study was to assess how presence of the F508del-CFTR revertants G550E and R1070W in CFTR influence variants without RE and RI. Remarkably, our data show that the presence of either of these revertants did not affect ΔRE5-F508del-CFTR processing, but both of them further increased processing (but not function) of ΔRI5-F508del-CFTR to almost levels of wt-CFTR: 92-96% (G550E) and 71-76% (R1070W).

In contrast, removal of RI5 from either of these F508del-CFTR revertants completely abolished their processing, emphasizing how important the different residues between RI5 and RI are for F508del-CFTR conformers partially rescued by the revertants.

Regarding wt-CFTR processing, G550E (at the NBD1:NBD2 dimer interface) also partially recovered the negative effect caused by RI5 removal. In contrast, R1070W (at the NBD1:ICL4 interface), negatively affected processing of wt-CFTR (to 69%) and of ΔRI5-wt-CFTR (from 44% to 11%), while not affecting ΔRI5-wt-CFTR. R1070W rescues F508del-CFTR because Trp1070 fills the gap created by deletion of residue Phe508. It is not surprising that it perturbs CFTR folding due to clashing of Phe and Trp residues. It is, nevertheless curious that R1070W affect more the processing ΔRI5-wt-CFTR than wt-CFTR, to levels of F508del-CFTR, suggesting that both changes affect the same region of the molecule. Rescue of both R1070W-wt-CFTR and R1070W-ΔRI5-wt-CFTR by VX-809 further supports this concept.

The most striking effect of ΔRI5, however, was the almost complete abolition of VX-770-stimulated current of G550E-F508del-CFTR to levels even lower than those observed for ΔRI5-F508del-CFTR (see above). It was suggested that VX-770 binds directly to CFTR to the MSDs (although it is not defined the exact binding site), in phosphorylation-dependent but ATP-independent manner and away from the canonical catalytic site. Both RD and RI were suggested by Eckford and colleagues as putative binding regions for VX-770. Nevertheless, the pharmacological effect of VX-770 remains robust in the absence of the RD and here we demonstrate that it does indeed require RI since VX-770 is unable to stimulate either ΔRI5-F508del-CFTR or ΔRI5-G550E-F508del-CFTR (see Fig.6).

Overall, our data show that while the presence of the regulatory insertion seems to be precluding full rescue of F508del-CFTR processing by VX-809, this region appears essential to rescue its function
Role of regulatory extension on CFTR stability.

by VX-770, thus suggesting some contradictory role in rescue of F508del-CFTR by these two modulators. Nevertheless, this negative impact of RI removal on VX-770-stimulated currents on F508del-CFTR can be compensated by deletion of the regulatory extension which also leads to the stabilization of this mutant. We thus propose that, despite both these regions being conformationally active, RI precludes F508del-CFTR processing while RE affects mostly its stability and channel opening.
