Abstract

Retinoblastoma 1 (RB1) has been extensively studied in mammalian species, but its function in avian species is unclear. The objective of this study was to reveal the role of chicken RB1 (Gallus gallus RB1, gRB1) in the proliferation of preadipocytes. In the current study, quantitative real-time PCR analysis showed that the expression levels of gRB1 transiently increased during the proliferation of preadipocytes. The MTT assay showed that gRB1 overexpression suppressed preadipocyte proliferation, and gRB1 interference promoted preadipocyte proliferation. Additionally, cell-cycle analysis indicated that gRB1 may play a crucial role in the G1/S transition. Consistently, gene expression analysis showed that gRB1 knockdown promoted marker of proliferation Ki-67 (MKi67) expression at 96 h ($P < 0.05$), and that overexpression of gRB1 reduced MKi67 expression at 72 h ($P < 0.05$). Together, our study demonstrated that gRB1 inhibited preadipocyte proliferation at least in part by inhibiting the G1 to S phase transition.

Keywords: Chicken; Preadipocytes; Cell-cycle; Retinoblastoma 1 (RB1)
Introduction

The selection for rapid growth in meat-type chickens has been accompanied by increased abdominal fat deposition [1]. Excessive abdominal fat deposition can decrease feed efficiency and carcass quality, leading to consumer rejection of the meat [2-4]. The excessive deposition of abdominal fat is mainly due to the excessive proliferation and differentiation of adipocytes in adipose tissues. Clarifying the genetic mechanisms of proliferation and differentiation of adipocytes will help control the excessive accumulation of abdominal fat.

In our previous study, we mapped a quantitative trait locus (QTL) with major effects on abdominal fat trait into a 3.7-Mbp (172.6–176.3 Mbp) region in chicken chromosome 1 using an F2 population of a broiler × layer cross [5]. In this 3.7-Mbp region, five genes, including Retinoblastoma 1 (RB1), were detected [6]. In the examination of genome-wide selection signatures of abdominal fat content with the chicken 60 k SNP chip and the extended haplotype homozygosity (EHH) assay, a number of genes in the significant core regions were detected, and the RB1 gene was detected once again [7]. In addition, polymorphism analysis of the RB1 gene of Northeast Agricultural University broiler lines divergently selected for abdominal fat content (NEAUHLF) indicated that the polymorphisms of RB1 were associated with abdominal fat content (unpublished data). These results suggest that RB1 plays an important role in the deposition of abdominal fat in broiler chickens. However, the mode of action of RB1 in chicken abdominal fat deposition remains unknown, hence, the aim of this study was to analyze the function of RB1 in the proliferation of chicken preadipocytes.

Materials and methods

Ethics statement

All animal work was conducted according to the guidelines for the Care and Use of Experimental Animals established by the Ministry of Science and Technology of the People’s
Republic of China (approval number: 2006–398), and was approved by the Laboratory Animal Management Committee of Northeast Agricultural University.

**Preparation and culture of cells**

In the current study, the immortalized chicken preadipocyte line (ICP1) was used to analyze the function of RB1 in the proliferation of chicken preadipocytes. Primary chicken preadipocytes were isolated from the abdominal adipose tissue of 10-day-old Arbor Acres (AA) broilers, and then the primary chicken preadipocytes were infected with either chicken telomerase reverse transcriptase (chTERT) alone or in combination with chicken telomerase RNA (chTR) to establish immortalized chicken preadipocyte line (ICP1) [8]. ICP1 had survived >100 population doublings in vitro and displayed high telomerase activity and had no sign of replicative senescence [8]. This cell line shows great promise as an in vitro model for the investigation of chicken adipogenesis and lipid metabolism. ICP1 cells were maintained in DMEM F12 supplemented with 10% fetal serum and 1% penicillin and streptomycin. ICP1 cells were cultured until 90% confluence and then passaged and seeded in cell culture plates at a density of $1 \times 10^5$ cells/cm$^2$.

**Construction of RB1-overexpression plasmid and synthesis of siRNA-RB1**

To carry out the overexpression and RNA interference (RNAi) experiments, the RB1-overexpression plasmid was constructed and siRNA-RB1 was synthesized. The full-length coding sequence of chicken RB1 (Gallus gallus RB1, gRB1; GenBank accession number: NM_204419) was amplified from chicken abdominal adipose tissue cDNA using a pair of specific primers: sense, 5’-ACGTCGACAAACGTCACCATTGCCGCCC-3’; anti-sense, 5’-CCGCTCGAGCAGCCCTTGTCCTGAGGAGAATC-3’. The PCR product
was cloned into pEasy-T1 Simple vector (TransGen, Beijing, China) and verified by direct sequencing. The full-length coding sequence of gRB1 was excised from the pEasy-T1-gRB1 plasmid by digesting with SalI and XhoI, and subcloned into pCMV-HA vector (Clontech, Mountain View, CA, USA) to obtain the RB1-overexpression vector, pCMV-HA-gRB1.

The siRNA of the gRB1 selected for RNAi and the negative control were designed and synthesized by GenePharma Company (Shanghai, China; Table 1).

RNA Isolation and real-time RT-PCR

To detect the expression level of RB1, marker of proliferation Ki-67 (MKi67), Cyclin D1, proliferating cell nuclear antigen (PCNA) and Transcription factor E2F1 (E2F1) genes in preadipocytes, the RNA of the cells was isolated and real-time RT-PCR was carried out. Total RNA was isolated using Trizol reagent (Invitron, Monmouth, UK). RNA quality was assessed by denaturing formaldehyde agarose gel electrophoresis. Reverse transcription was performed using 1 μg of total RNA, an oligo (dT) anchor primer, and EasyScript reverse transcriptase (TransGen). Reverse transcription conditions for each cDNA amplification were 42°C for 30 min, and then 85°C for 5 min.

Real-time RT-PCR was carried out using the 7500 real-Time PCR System (Applied Biosystems, Foster City, CA, USA) and the TransStart Top Green qPCR SuperMix (TransGen). The primers for RB1, MKi67, Cyclin D1, PCNA, and E2F1 genes used for real-time RT-PCR are shown in Table 2. Non-POU domain-containing octamer-binding (NONO) was used as the internal reference gene. Dissociation curves were analyzed using the Dissociation Curve 1.0 software (Applied Biosystems) for each PCR reaction to detect and eliminate possible primer-dimer artifacts. Results (fold changes) are expressed as 2-ΔCt in
which $\Delta Ct = (Ct_{ij} - Ct_{rj})$, where $Ct_{ij}$ and $Ct_{rj}$ are the Ct for gene $i$ and reference gene $r$ in the sample (named $j$). The statistical significance of the differences in mRNA expression levels between groups was determined by the $t$-test.

**Western blot assays**

Western blot analysis was used to examine the effect of $gRB1$ overexpression. Chicken preadipocytes transfected with pCMA-HA-PPAR$\alpha$ (M1, positive control), pCMV-HA-$gRB1$ (M2, $gRB1$ overexpression), or pCMV-HA (M3, control) vector for 2 days were homogenized in RIPA buffer (PBS, pH 7.4, containing 1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, and a protease inhibitor cocktail) supplemented with protease inhibitors (1 mmol/L phenylmethylsulfonyl fluoride, 0.002 g/L aprotinin, and 0.002 g/L leupeptin). Cellular debris and lipids were eliminated by centrifuging the solubilized samples at $13,000 \times g$ for 60 min at 4°C. Cell lysates were separated by 5–12% SDS-polyacrylamide gels and transferred to polyvinylidene difluoride membranes. To block nonspecific binding, the membrane was incubated in blocking buffer (PBS with 5% nonfat dry milk) for 1 h at room temperature. After incubation with the primary antibody for HA-tag (1:200; Clontech) or $\beta$-ACTIN (1:1000; TransGen), a secondary horseradish peroxidase-conjugated antibody was added, and then a BeyoECL Plus kit (Beyotime, Jiang Su, China) was used for visualizing the protein bands.

**The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay**

The MTT assay was used to examine the effects of overexpression or knockdown of $gRB1$ on ICP1 cells proliferation. ICP1 cells were transfected with the $gRB1$-overexpression plasmid or siRNA nucleotides for the knockdown of $RB1$ expression, as well as the control
plasmid or negative control nucleotides (siNC), respectively. After a 24-h incubation, these cells were passaged and seeded in 96-well plates at a concentration of 5000 cells per well. At the designated time points (including 12, 24, 48, 72, and 96 h), 20 mL of MTT solution (5 mg/mL; Sigma) were added to the medium, and the cells were incubated at 37°C for 4 h. After removal of the medium, 200 mL of DMSO were added to each well, and the plates were shaken on a rocking platform at 60 × g for 15 min. The cell solution was collected and the absorbance was recorded with an enzyme-labeled instrument (Bio-Rad, Hercules, CA, USA) at 492 nm. The experiments were repeated biologically three times. For each biological repeat, there were two groups, treatment group and control group, and cells were collected at 12, 24, 48, 72, and 96 h. At each time point, there were three wells technical duplications. Only the result of one biological repeat was shown in the current study, because the results of the three biological repeats were similar with each other.

Cell-cycle analysis

After overexpression or knockdown of gRB1 for 48 h, ICP1 cells were trypsinized and subsequently fixed with ice-cold 70% ethanol for at least 1 h. After extensive washing, the cells were suspended in propidium iodide (PI) staining solution (Beyotime), fully resuspended slowly, and bathed at 37°C for 30 min in the dark for subsequent FACScan analysis (Becton-Dickinson, San Jose, CA, USA). Cell-cycle analysis was performed by the ModFit LT software (Verity Software House, Topsham, ME, USA). The experiments were repeated biologically three times. Each biological repeat included three wells technical duplications. Only the result of one biological repeat was shown in the current study, because the results of the three biological repeats were similar with each other.

146  **Statistical analysis**

147  Data are expressed as mean ± SD. Comparison between two groups was performed by
148  the unpaired two-tailed Student’s t-test. Statistical analysis among more than two groups was
149  performed using ANOVA method.

150  **Results**

151  **gRB1 gene expression during chicken preadipocyte proliferation**

152  The expression of *gRB1* during the proliferation of chicken preadipocytes was analyzed
153  using real-time PCR. The cells were collected at 24, 48, 72 and 96 h, and the *NONO* gene
154  was used as the internal reference. The results showed that the mRNA expression level of
155  *gRB1* in chicken preadipocytes initially increased and then decreased, with a peak at 72 h
156  (Fig 1).

157  **Effect of gRB1 on chicken preadipocyte proliferation**

158  To explore the effect of *gRB1* on the proliferation of chicken preadipocytes, overexpression and RNAi experiments were carried out. The pCMV-HA-*PPARα* plasmid
159  with a length of 52.19 kDa, which we successively constructed previously, was used as the
160  positive control, and the pCMV-HA was used as the negative control. The western blot
161  analysis results showed that pCMV-HA-*gRB1* expressed the RB1 protein in chicken
162  preadipocytes (Fig 2A). The MTT assay results showed that overexpression of *gRB1*
163  significantly suppressed the proliferation of ICP1 cells at 24 and 48 h (Fig 2B).

164  For the RNAi experiment three interference fragments were used, which were named
165  *siRB1*-409, *siRB1*-551 and *siRB1*-1680. The interference effect of these three different
166  siRNAs was examined and the results indicated that *siRB1*-551 and *siRB1*-1680 significantly
knocked down the gRB1 gene expression level compared with the control group ($P < 0.05$; Fig 2C). siRB1-1680 had the strongest interference effect, hence it was used to investigate the role of the gRB1 gene in the proliferation of chicken preadipocytes in the following experiment. We analyzed the interference effect of siRB1-1680 on gRB1 expression at different time points and found that the knockdown effect was the most significant at 48 h (Fig 2D). The MTT results indicated that knockdown of gRB1 promoted the proliferation of ICP1 cells and that the effect was significant at 96 h compared with the negative control (Fig 2E).

**Effect of gRB1 on the cell cycle of chicken preadipocytes**

The MTT results indicated that gRB1 suppressed the proliferation of preadipocytes. To explore whether the suppression is caused by changes in the cell cycle, the effects of gRB1 on the cell cycle of preadipocytes (ICP1) were analyzed using overexpression and RNAi methods. The effects of gRB1 on the cell cycle of preadipocytes (ICP1) were examined at 48 h after transfection, because the overexpression and interference effects were the most significant at that time point. The overexpression results showed that the proportion of preadipocytes (ICP1) in the G1 and G2 phases significantly increased ($P < 0.05$), and the proportion of preadipocytes (ICP1) in the S phase significantly decreased ($P < 0.05$; Fig 3A). The RNAi results showed that the proportion of preadipocytes (ICP1) in the S phase significantly increased ($P < 0.05$) after the downregulation of the gRB1 gene (Fig 3B).

**Effect of gRB1 on the expression levels of genes related to chicken preadipocyte proliferation**
In the current study, the effects of \( gRB1 \) on the expression levels of genes related to the proliferation of chicken preadipocytes, including \( MKi67, PCNA, E2F1 \) and \( Cyclin D1 \), were also analyzed. ICP1 cells were seeded in 6-well plates. The time point at which cell confluence reached 30–50% was the 0 h. At this time point, si\( RB1 \)-1680, siNC, pCMV-HA-g\( RB1 \), or pCMV-HA was transfected into the preadipocytes. The preadipocytes were collected at 24, 48, 72, and 96 h, and RNA was extracted. The \( NONO \) gene was used as the internal reference. The results showed that the expression level of \( MKi67 \) significantly decreased at 72 h (\( P < 0.05 \)) and the expression levels of \( E2F1, PCNA \) and \( Cyclin D1 \) did not significantly change after \( gRB1 \) overexpression (Fig 4A). In contrast, the expression level of \( MKi67 \) significantly increased at 96 h (\( P < 0.05 \)), the expression levels of \( E2F1, PCNA \) and \( Cyclin D1 \) did not significantly change after \( gRB1 \) gene knockdown (Fig 4B).

Discussion

In the current study, we used overexpression and RNAi methods to reveal the role of \( gRB1 \) gene expression in the proliferation of chicken preadipocytes. The MTT results showed that overexpression of \( gRB1 \) suppressed preadipocyte proliferation and \( gRB1 \) knockdown promoted the proliferation of chicken preadipocytes, indicating that \( gRB1 \) suppressed the proliferation of preadipocytes in chickens. These results are consistent with studies that showed that mouse \( RB1 \) inhibited the proliferation of 3T3-L1 cells [9], knockdown of \( RB1 \) in porcine could increase the mRNA levels of adipogenic markers, such as \( PPAR\gamma \), \( aP2 \), \( LPL \) and adiponectin [10], and human \( RB1 \) inhibited the proliferation of cancer cells, including retinoblastoma [11], prostate cancer [12], and lung cancer cells [13].

Here, we found that the proportion of preadipocytes in the G1 phase significantly...
increased ($P < 0.05$) and the proportion of preadipocytes in the S phase significantly decreased ($P < 0.05$) after overexpression of the $gRB1$. In addition, when the expression level of $gRB1$ gene was knocked down, the proportion of preadipocytes in the S phase significantly increased ($P < 0.05$) and the proportion of preadipocytes in the G1 phase had a tendency to decrease. These results indicated that $gRB1$ inhibited the cell cycle of preadipocytes, mainly by inhibiting the G1 to S phase transition, resulting in G1 arrest. These results are consistent with studies on mammals that showed that RB1 is a negative regulator of the cell cycle, as it primarily binds to E2F, thereby preventing the progression of cells through the G1/S phase, resulting in cell-cycle arrest [14-17].

In our study, four cell-cycle-related genes, including $MKi67$, $PCNA$, $E2F1$, and $CyclinD1$, were selected to determine the mechanism of the effect of $gRB1$ on the cell cycle. $MKi67$ is a nuclear protein that is associated with and may be necessary for cellular proliferation [18,19]. Additionally, inactivation of $MKi67$ leads to inhibition of ribosomal RNA synthesis [20,21]. The results of the current study showed that $gRB1$ overexpression inhibited the expression level of $MKi67$ at 72 h, and that $gRB1$ knockdown promoted the expression level of $MKi67$ at 96 h. These results indicated that $gRB1$ decreased the expression level of $MKi67$. This result is consistent with studies showing that RB1 suppressed the proliferation of human cells and that $MKi67$ protein promoted cell proliferation [16,18].

Proliferating cell nuclear antigen ($PCNA$), a good indicator of cell proliferation, is a cofactor of DNA polymerase $\delta$, and plays an important role in the initiation of cell proliferation [22-25]. The current study showed that the expression level of $PCNA$ increased at 48 and 72 h after $gRB1$ knockdown, and decreased at 72 and 96 h after $gRB1$
overexpression using NONO as the internal reference gene. Though these results were not statistically significant, they imply that gRB1 decreased the expression level of PCNA. This result is consistent with studies showing that RB1 suppressed the proliferation of human cells and PCNA promoted cell proliferation [16,25].

E2F1 acts as a transcription factor of genes involved in cell-cycle progression, DNA replication, DNA repair, and apoptosis [26,27]. In human cells, E2F1 binds preferentially to retinoblastoma protein (pRb) in a cell-cycle-dependent manner and can mediate both cell proliferation and p53-dependent/independent apoptosis [28]. Here, the mRNA expression level of E2F1 did not significantly change after knockdown or overexpression of the gRB1 gene. This suggests that the interaction between gRB1 and E2F1 may not be at the transcriptional level, but at the translation level, similarly to the case in mammals [28]. In mammals, pRb interacts with the E2F1 protein and plays important functions in DNA replication and cell proliferation [28,29].

Cyclin D1 is a cell-cycle protein and is an important regulatory factor of the G1 to S phase transition [30,31]. Cyclin D1 and E2F participate in the regulation of cell-cycle-based networks of pRb [32]. Here, the expression level of Cyclin D1 did not significantly change after knockdown or overexpression of the gRB1 gene. This result also indicates that the interaction between gRB1 and Cyclin D1 may not be at the transcriptional level, but at the translation level, as is the case in mammals [33,34]. In mammals, Cyclin D1 may be able to independently regulate the activity of pRb [34].

In summary, our results showed that gRB1 is a negative regulator of chicken preadipocyte proliferation, and that it inhibited the cell cycle of preadipocytes through G1
arrest.
