29   **ABSTRACT (228)**

30   Congenital toxoplasmosis is a parasitic disease that occurs due vertical transmission
 31   of the protozoan *Toxoplasma gondii* (*T. gondii*) during pregnancy. The parasite crosses the
 32   placental barrier and reaches the developing brain, infecting progenitor, glial, neuronal and
 33   vascular cell types. Although the role of Radial glia (RG) neural stem cells in the
 34   development of the brain vasculature has been recently investigated, the impact of *T. gondii*
 35   infection in these events is not yet understood. Herein, we studied the role of *T. gondii*
 36   infection on RG cell function and its interaction with endothelial cells. By infecting isolated
 37   RG cells with *T. gondii* tachyzoites, we observed reduced cell proliferation and
 38   neurogenesis without affecting gliogenesis levels. Conditioned medium (CM) from RG
 39   control cultures increased ZO-1 and β -catenin protein levels and organization on
 40   endothelial bEnd.3 cells membranes, which was completely impaired by CM from infected
 41   RG, resulting in decreased transendothelial electrical resistance (TEER). Cytokine Bead
 42   Array and ELISA assays revealed the presence of increased levels of the pro-inflammatory
 43   cytokine IL-6 and reduced levels of anti-inflammatory cytokine TGF- β 1 in CM from *T.*
 44   *gondii*-infected RG cells. Treatment with recombinant TGF- β 1 concomitantly with CM from
 45   infected RG cultures led to restoration of ZO-1 staining in bEnd.3 cells. Our results suggest
 46   that infection of RG cells by *T. gondii* modulate cytokine secretion, which might contribute to
 47   endothelial loss of barrier properties, thus leading to impairment of neurovascular
 48   interaction establishment.

1) INTRODUCTION (904)

Toxoplasmosis is a parasitic disease that affects all warm-blooded animals, including humans. The disease is caused by a protozoan parasite, *T. gondii* and has a high global seroprevalence, estimated in approximately 1/3 of the world's population (Dubey, 2010). Transmission occurs by ingestion of uncooked meat from infected animals, that contains tissue cysts, or by ingestion or inhalation of sporulated oocysts, shed with feces of infected felids. The cysts are digested by proteolytic enzymes present in the stomach and small intestine, which then release infective parasites that rapidly invade epithelial cells of the small intestine and differentiate into fast-replicating tachyzoite forms. After intense intracellular proliferation, parasites promote host cell lysis and can disseminate throughout the entire organism (reviewed in Hill and Dubey, 2016). During the acute phase, patients may present lymphadenopathy, which may be associated with fever, fatigue, muscle pain, sore throat and headaches (Montoya and Liesenfeld, 2004).

T. gondii can also be vertically transmitted during gestation, leading to Congenital Toxoplasmosis (CT), established by the capacity of the parasite to cross the placental barrier and reach the developing brain tissue, where both tachyzoites and tissue cysts can be found in the developing brain parenchyma (Ferguson et al., 2013). CT is part of the TORCH complex of infectious diseases (Toxoplasma, Rubella, Cytomegalovirus, Herpes simplex 2. O stands for Others, and includes chlamydia, HIV, Coxsackievirus, Syphilis, Hepatitis B, chicken pox and Zika virus) that can be transmitted from the mother to the fetus (Neu et al., 2015; Mehrjardi, 2017). Infection with some of these pathogens can potentially lead to congenital defects including, but not limited to, microcephaly, growth and mental retardation, heart disease and hearing loss (Neu et al., 2015; Klase et al., 2016). Although transmission during the third trimester has been implicated in reduced impact on the fetus, infection during the first trimester is extremely disruptive, with severe neurological manifestations including microcephaly, cognitive/intellectual disabilities, deafness and blindness (Wallon et al., 1999).

Deleterious effects of infection of mouse neural progenitor cells by a highly infective *T. gondii* strain was linked to apoptosis induction by endoplasmic reticulum stress signaling pathway activation (Wang et al., 2014). In addition, reduced neuron and astrocyte generation from the neural C17.2 stem cell line by disruption of the Wnt/ β -catenin signaling pathway have also been suggested as an underlying mechanism of *T. gondii*-induced neural pathological damage during brain development (Gan et al., 2016; Zhang et al., 2017).

RG cells are the major multipotent neural stem cell population present during the embryonic cerebral cortex development period and originate most of the neuronal and glial cell types found in neural tissue, by activation of multiple signaling pathways (Gotz and Barde, 2005; Kriegstein and Alvarez-Buylla, 2009; Stipursky et al., 2012; Stipursky et al., 2014). Besides its well-known role as neural stem cells, RG have recently been demonstrated to directly control vascular development and blood brain barrier (BBB) formation in the embryonic cerebral cortex (Ma et al., 2013; Errede et al., 2014; Hirota et al., 2015; Siqueira et al., 2017).

We have previously demonstrated that the gliogenic and neurogenic potential of RG cells during cerebral cortex development is controlled by TGF- β 1 signaling pathway activation, both *in vitro* and *in vivo* (Stipursky et al., 2012; Stipursky et al., 2014). Neuroepithelial and RG neural progenitors interact with immature endothelial cells, derived from the perineural vascular plexus (PNVP) that surrounds the neural tissue early during the embryonic period. Such an interaction is essential to promote invasion of endothelial cells and vascularization of the developing CNS. Endothelial cells from the PNVP invade forebrain tissue as early as E9.5 in mice and migrate towards the ventricular surface, guided by VEGF gradients secreted by neural progenitor cells (Bautch and James, 2009; Anderson et al., 2011; Liebner et al., 2011; Takahashi et al., 2015). Recently, we demonstrated that RG cells coordinate the formation of the vascular tree of the brain, by controlling angiogenesis in the developing cortex. Specifically, RG cells secrete a vast

105 repertoire of pro-angiogenic factors, including TGF- β 1 and VEGF-A, that induce endothelial
106 proangiogenic genes expression and regulate migration and blood vessel branching in the
107 embryonic cerebral cortex (Siqueira et al., 2017).

108 Blood vessel development and neural cell generation in the CNS are essential steps
109 for the establishment of the BBB. The BBB is a multicellular structure formed by capillary
110 endothelial cells, astrocytic endfeet, pericytes and neighboring microglia and neurons, that
111 control the transport of nutrients, oxygen and other substances, and prevent the free
112 passage of toxic agents and pathogens (Kim et al., 2006; Anderson et al., 2011). In the
113 adult brain, *T. gondii* can infect endothelial cells (Konradt et al., 2016) and, by modulation of
114 adhesion proteins, contribute to decreased adhesion between adjacent endothelial,
115 allowing for transmigration of inflammatory cells into the brain parenchyma (Lachenmaier et
116 al., 2011).

117 Although RG physiology greatly determines the correct formation of the cerebral
118 cortex, including its vascularization (Ma et al., 2013; Errede et al., 2014; Hirota et al., 2015;
119 Siqueira et al., 2017), the understanding of the impact of *T. gondii* infection on RG-
120 endothelial interactions in the embryonic CNS has never been addressed.

121 Here, we investigated the role of *T. gondii* infection on RG physiology and its potential
122 to control endothelial barrier properties establishment. We demonstrated that infection
123 reduce the neurogenesis potential and altered the RG secretome. Such altered alterations
124 lead to important dysfunctions in microvascular brain endothelial cells, presenting reduced
125 tight junction stability and barrier properties when incubated with a conditioned medium
126 obtained from infected RGs.

127

128 **2) MATERIAL AND METHODS (1229)**

129 **2.1) Compliance with Ethical Standards:** All animal protocols were approved by the
130 Federal University of Rio de Janeiro Animal Research Committee (CEUA 041/14). Animals

131 were housed in a temperature-controlled room with a 12/12 h light/dark cycle and allowed
132 food and water *ad libitum*.

133 **2.2) *Toxoplasma gondii* infection:** Parasites from the ME49 strain were obtained
134 from the brains of C57/bl6 mice infected 45 days before isolation. Cysts were ruptured with
135 an acid pepsin solution and free parasites were added to monolayers of Vero cells
136 (ATCC® CCL-81™). After two weeks of culture re-infections, tachyzoites released from the
137 supernatant were collected and centrifuged. Cell cultures were infected with the tachyzoites
138 at a multiplicity of infection (MOI) of 3 parasites:host cell (Luder et al., 1999) for 2 hours in
139 300 µL of DMEM-/F12/2% B27/ Penicilin-streptocycin (Thermo) (RG cultures). Cells were
140 washed in Ringer's solution, fresh culture media was added, and cultures were kept for
141 additional 22 hours, when conditioned medium was collected and cells fixed for
142 immunostaining. Mock-infected cultures (treated with fresh culture medium) were used as
143 controls.

144 **2.3) *Radial glia (RG) cultivation:*** RG isolation from E14 gestational day-old Swiss
145 mouse embryos was carried out as previously described by Stipursky et al. (2014). Briefly,
146 gestational day14 Swiss mice embryos were collected and dissected for cerebral cortex
147 separation. After dissection, tissues were dissociated in DMEM/F12 Glutamax high glucose
148 (Thermo) medium and after cell counting, $3 \cdot 10^5$ cells were plated in 25 cm² culture flasks in
149 neurosphere "growing media" DMEM/F12 Glutamax high glucose (Thermo) containing
150 0.1% penicillin/streptomycin, 2% B27 (Thermo), 20ng/mL EGF (epidermal growth factor,
151 Thermo) and 20 ng/mL FGFb (basic fibroblast growth factor, R&D Systems), for 6 days, *in*
152 *vitro*. 2/3 of the media was changed every 2 days. After this period, neurospheres were
153 enzymatically dissociated in 0.05%Trypsin/EDTA (Thermo). After cells isolation, $2 \cdot 10^5$ cells
154 were plated on glass coverslips previously coated with 5 µg/mL laminin (Thermo) and
155 incubated in DMEM/F12 Glutamax (high glucose) without serum and supplemented with
156 2% B27, 20 ng/mL FGFb and EGF (Thermo). Twenty-four hours after plating, cells were
157 infected with the tachyzoite forms of the *T. gondii*, ME49 strain as described above. After
158 infection, cells were gently washed to remove extracellular parasites and 300 µL of fresh

159 DMEM/F12/ medium were added, followed by 22 hours of incubation. Next, non-infected
160 and infected RG cells were fixed with paraformaldehyde 4% solution in PBS (Sigma-
161 Aldrich) for immunocytochemistry assays. Supernatants were collected, centrifuged for 10
162 min at 10,000 rpm (4 °C) to eliminate cell debris and extracellular parasites and frozen at -
163 80 °C to be further used as a Conditioned Medium (CM) or for cytokine measurements.

164 **2.4) Enzyme-Linked Immunosorbent Assay (ELISA):** TGF- β 1 levels present in the
165 conditioned medium derived from non-infected (RG-CM) and infected (Inf-RG-CM) RG
166 cells, were measured by the Mouse TGF- β 1 ELISA DuoSet Kit (R&D Systems) following
167 the manufacturer's instructions.

168 **2.5) Cytometric Bead Array (CBA):** Cytokine levels were evaluated by flow
169 cytometry in culture RG-CM and Inf-RG-CM supernatants. IL-10, IL-17, TNF, IFN- γ , IL-6, IL-
170 4 and IL-2 were detected using a Cytometric Bead Array (CBA) Th1/Th2/TH17 kit (BD),
171 according to the manufacturer's instructions. Samples were acquired using a FACScalibur
172 flow cytometer (BD), and the data analysis was performed using the CBA analysis FCAP
173 software (BD).

174 **2.6) bEnd.3 cell line cultivation:** A total of 6.10^4 murine brain microvascular
175 endothelial cells (bEnd.3, ATCC® CRL-2299™) were plated on glass coverslips previously
176 coated with 0.01% porcine gelatin solution (Sigma-Aldrich) in bEnd.3 medium [DMEM/F12
177 Glutamax high glucose (4500 mg/L) with 10% heat-inactivated Fetal Bovine Serum
178 (Cultilab) and 1% penicillin/streptomycin solution (Thermo)] for 14 days, with the medium
179 changed every 2 days. After reaching confluence, cultures were treated with RG-CM, Inf-
180 RG-CM, Inf-RG-CM+TGF- β 1 (10ng/ML, R&D Systems) or TGF- β 1 (10ng/mL) for 24 hours.
181 Cultures were fixed with PFA 4% for immunocytochemistry assays. Cells were used
182 between passages 25 to 30.

183 **2.7) Immunocytochemistry:** Immunostaining was performed as previously described
184 by Siqueira et al. (2017). Briefly, fixed cultures were permeabilized for 5 min with 0.05%
185 Triton x-100 solution in PBS and non-specific binding blocked by incubation with blocking
186 solution containing 5% Bovine Serum Albumin (BSA - Sigma-Aldrich)/2.5% Normal Goat

187 Serum (NGS)/PBS for 1 hour. Cells were incubated with primary antibodies, diluted in
188 blocking solution and maintained overnight at 4°C. For RG cultures, immunostaining
189 primary antibodies were: mouse anti-Nestin (marker of neural progenitor cells, Millipore,
190 1:200); rabbit anti-BLBP (marker of radial glia cells, Chemicon, 1:500), rabbit anti-Ki67
191 (nuclear marker of mitotic cells, Abcam, 1:100), rabbit anti-GFAP (intermediary filament
192 protein specific to glial cells, Dako Cytomation, 1:500) and mouse anti- β -III-tubulin (specific
193 isoform found in immature neurons, Promega, 1:1000), and mouse anti-cleaved Caspase 3
194 (apoptosis cell marker, Abcam, 1:100). For endothelial culture immunostaining, primary
195 antibodies were: mouse anti-ZO-1 (Invitrogen, 1:300), rabbit anti- β -catenin (Sigma-Aldrich,
196 1:200). Subsequently, cells were extensively washed in PBS and incubated with secondary
197 antibodies, conjugated to AlexaFluor 488 or AlexaFluor 546 (Thermo), for 2 h at room
198 temperature. Nuclei were DAPI-labeled (4', 6-Diamidino-2-phenylindole; Sigma-Aldrich).
199 Glass coverslips were mounted in glass slides with Faramount mounting media (Dako
200 Cytomation) and visualized under a fluorescence optical microscope Nikon TE3000 or a
201 Leica SPE confocal microscope. Fifteen random images under a 40x objective were
202 acquired from each glass coverslip from at least 3 independent experiments done in
203 triplicate.

204 **2.8) Trans-Endothelial Electrical Resistance (TEER):** bEnd.3 cells were plated
205 onto 0.01% gelatin-coated Transwell inserts (Falcon) with 3 μ m pores at a density of 10^5
206 cells per insert. Cultures were maintained in bEnd.3 medium at 37°C in 5% CO₂
207 atmosphere and resistance was measured daily using a Millicell-Electrical Resistance
208 System (Millipore, Bedford, MA) with an adjustable electrode ("chopstick electrode",
209 MERSSTX03), as described by Srinivasan et al., 2015. Cells reached confluence after
210 approximately 14 days (minimum of 60 Ω x cm²), with the medium changed every 2 days.
211 One electrode is inserted into the upper trans-well insert compartment and the other
212 electrode to the lower compartment. Care is taken to ensure that all compartments have the
213 same volume of medium across biological and technical replicas (300 ml in the upper
214 compartment and 600 ml in the lower). A square wave current of 12.5 Hz is applied to the

215 electrodes and the resulting current is measured. To calculate TEER, the background
216 resistance reading from an empty insert was subtracted from the resistance reading for
217 each condition and the result was multiplied by 0.33, relative to the insert area, and results
218 were expressed as $\Omega \times \text{cm}^2$. One insert per experiment was maintained in bEnd.3 medium
219 (10% FBS), while experimental data was obtained from cultures incubated with DMEM/F12
220 high glucose with antibiotics solution and no FBS. Cells were used for experiments when
221 TEER reached a minimum of $60 \Omega \times \text{cm}^2$. TEER was obtained before experimental
222 procedures ($t=0$) and 24 h after treatments with CMs or infection ($t=24$). The variation index
223 for each experimental condition was calculated as $\text{TEER}_{t=24}/\text{TEER}_{t=0}$.

224 **2.9) Quantification and statistical analyses:** Quantification analyses of cell
225 populations (RG, neurons and astrocytes) were carried out manually using the Photoshop
226 CS6 software. The percentage of each stained cell population, in each microscopic field,
227 was calculated in relation to total DAPI stained cells numbers in the same field. bEnd.3
228 labeling intensity analysis was carried out using the ImageJ software and the TiJOR
229 analysis was performed using the TiJOR macro for ImageJ, which in an index of localization
230 of tight junction proteins in membrane-membrane contact region of adjacent cells as
231 described by Terryn et al. (2013). The GraphPad Prism 6.0 software was used for the
232 statistical analyses, obtained at <http://www.graphpad.com/scientific-software/prism>.
233 Statistical significance from at least 3 independent experiments was determined by
234 unpaired t-test and ANOVA for biological effects with an assumed normal distribution. P
235 value <0.05 was considered statistically significant.

236

237

3) RESULTS (767)

3.1) *T. gondii* infection alters Radial Glia cell numbers and neurogenesis.

In order to understand the effects of *T. gondii* infection on the RG differentiation potential, isolated RG cells from E14 cerebral cortex were infected with the tachyzoite forms of the parasite. We used the cells 24 hours after neurosphere dissociation and plating. At this time, Radial glia cultures are virtually pure with 96% of cells positive for blbp and 95.7% positive for nestin (92% were blbp/nestin double positive, Stipursky J., personal communications). After 24 hours of infection with *T. gondii*, mock-infected (control) cells displayed typical radial bipolar morphology and expression of typical RG neural stem cells markers BLBP and Nestin, *in vitro* (**Figure 1A**). Parasites were detected in the cytoplasm of Nestin-positive cells (**Supplementary Figure 1C-D**). Infected cultures presented a 40% decrease in the number of BLBP/Nestin double-labeled cells (**Figure 1 A-C**). This event was accompanied by a 25 % decrease in proliferative RG cells double labeled for Ki67 and Nestin markers (**Figure 1 D-E**). In parallel, *T. gondii* infection also significantly decreased the numbers of early neurons (as detected by β -III-tubulin labeling) by 36% (**Figure 1 G-I**). However, no effect on the number of astrocytic (GFAP-positive) cells was detected in infected cultures compared to the controls (**Figure 1 J-L**). The average of total cells number of β -TubulinIII and Nestin positive cells double labeled for the apoptotic marker cleaved-Caspase 3 was not affected by infection (**Supplementary Figure 2A**). Overall, *T. gondii*-infected cultures presented a shift in the percentage of cell composition when compared to uninfected controls, with Nestin/BLBP and β -III-tubulin positive cells being directly affected, although other unidentified cell types also tended to present percentage alterations, increasing from 17% in controls to 40% in infected cultures (**Figure 1M**).

3.2) *T. gondii* infection affects RG potential to control endothelial barrier property.

To investigate the potential of RG cells to control endothelial cells function and the role of *T. gondii* infection in this context, we cultivated b.End3 endothelial cells until

266 confluence. Through immunocytochemistry analyses, we identified ZO-1 adapter tight
267 junction protein mainly distributed along cell-cell contacts in the control condition (**Figure**
268 **2A**). Treatment of endothelial cells with conditioned medium derived from uninfected RG
269 cells (RG-CM) for 24 h significantly increased the ZO-1 labeling intensity levels by 36%
270 (**Figure 2B, D**). This was concomitant with an increase in organization levels of the tight
271 junctions (TiJOR) by 90% (**Figure 2 E**). However, treatment of endothelial cells with
272 conditioned medium derived from infected RG cells (Inf-RG-CM) completely abrogated RG
273 potential to induce ZO-1 labeling intensity, by 40%, when compared to control cultures,
274 although the TiJOR index did not differ from the controls (**Figure 2 C, D**). In summary, Inf-
275 RG-CM-treated presented deleterious effects on tight junction protein levels and
276 organization.

277 Additionally, a functional trans-endothelial electrical resistance (TEER) assay was
278 performed to investigate whether the structural tight junction modifications observed herein
279 were accompanied by alterations in endothelial monolayer barrier properties. Cultivation of
280 endothelial cells with RG-CM for 24 h increased TEER barrier properties by 22%. However,
281 addition of Inf-RG-CM completely impaired RG-induced increases in barrier properties,
282 although no significant alterations were observed in cell morphology. Treatment with Inf-
283 RG-CM decreased TEER barrier properties by 27% when compared to the controls (**Figure**
284 **2 F**).

285 The role of RG infection on the distribution of the pro-angiogenic signaling protein β -
286 catenin in endothelial cells was also investigated. The deleterious effect of Inf-RG-MC seen
287 in TiJOR and TEER was also true for β -catenin protein distribution on bEnd.3 cells
288 monolayers. In the control condition, β -catenin colocalized with ZO-1 along cell-cell
289 contacts (**Figure 2 G, J, M**). The RG-CM treatment significantly increased β -catenin
290 immunolocalization at junctional regions, which was impaired by Inf-RG-CM treatment
291 (**Figure 2 H, K, N and I, L, O**).

292

293   **3.3) *T. gondii*-infected RG cultures present altered cytokine secretion that**
 294   **affects endothelial cell barrier properties.**

295   To gain insight into the possible alterations induced by *T. gondii* on the RG secretory
 296   protein repertoire, a CBA analysis was carried out to measure the inflammation related
 297   factors IL-2, IL-4, IL-6, IL-10, IL-17, IFN- γ and TNF- α , followed by an ELISA analysis for
 298   the neuroprotector TGF- β 1, to measure the levels of these cytokines in the RG-CM and
 299   Inf-RG-CM. No detectable levels of IL-2, IL-4, IL-10, IL-17, IFN- γ and TNF- α , in the
 300   conditioned mediums were observed. CM from infected RG cultures showed IL-6 in
 301   increased concentrations (7.4 pg/ml) when compared to CM from control RG-CM (0.3
 302   pg/ml, $p < 0.01$, unpaired t test). TGF- β 1 levels were 40% decreased in Inf-RG-CM when
 303   compared to uninfected cultures (18 versus 29 pg/ml, $p < 0.05$, Unpaired Student's T test)
 304   **(Figure 3A).**

305   Since TGF- β 1 has a crucial role on brain microvasculature, we treated bEnd.3 cells
 306   with Inf-RG-CM together with recombinant TGF- β 1 (10ng/mL) for 24 hours and performed
 307   immunocytochemistry for ZO-1. Addition of TGF- β 1 to Inf-RG-CM completely rescued the
 308   ZO-1 labeling intensity to levels comparable to RG-CM condition, similarly to addition of
 309   TGF- β 1 alone **(Figure 3 B).**

310

311

4. DISCUSSION (2200)

4.1) RG differentiation potential is impaired by *T. gondii* infection

RG cells have been extensively investigated concerning several features, including neuronal migration support and multipotent neural stem cell potential in generating neurons, astrocytes, oligodendrocytes and other progenitor subtypes in the cerebral cortex (Rakic, 1999; Noctor et al., 2001; Morest and Silver, 2003; Barnabe-Heider et al., 2005; Stipursky and Gomes, 2007; Kessarar et al., 2008; Kriegstein and Alvarez-Buylla, 2009; Ortega and Alcantara, 2010; Stipursky et al., 2012; Stipursky et al., 2014). Evidence suggest that neural progenitors are directly affected by the TORCH complex of perinatal infectious diseases that, ultimately, lead to malformations in the cerebral cortex, such as microcephaly, mostly by disrupting neural cells generation (Neu et al., 2015). Regarding infection with *T. gondii*, recent findings point to increased apoptosis and reduced cell differentiation in the C17.2 neural stem cell line (Gan et al., 2016; Wang et al., 2014; Zhang et al., 2017). However, further characterization and evaluation of the effects of *T. gondii* infection on primary RG cells isolated from embryonic cerebral cortex have not yet been addressed. The present study indicates that *T. gondii* significantly decreases the number of Nestin/BLBP positive RG cells, possibly by decreasing their proliferation. Accordingly, previous data describe that altered neural stem cell proliferation, differentiation and apoptosis can be triggered by viral infection (Gan, 2016; Souza et al., 2016). In our model, RG cells accounted for 51% of the total cell population in the control condition after a total period of 48 h of cultivation. Since the total number of cells and the small percentage of apoptotic RG cells were not affected by *T. gondii* infection, it is possible that global cytotoxic infection effects were not the mechanism leading to reduced numbers of, specifically, Nestin/BLBP positive RG cells. Although RG cells have been described by our group and others to differentiate into astrocytes at later stages of cortical development (Rakic, 1971; de Azevedo et al., 2005; Stipursky and Gomes, 2007; Stipursky et al., 2012; Stipursky et al., 2014), no alterations in astrocyte differentiation by *T. gondii* infection were observed. Secreted levels of IL-6 and

340 TGF- β 1, two cytokines known to positively mediate astrocyte differentiation from neural
 341 progenitor cells (Taga and Fukuda, 2005; Nakamura et al., 2005, Stipursky and Gomes,
 342 2007; Stipursky et al., 2012; Stipursky et al., 2014), were altered in Inf-RG-CM. However, it
 343 is possible that, in this context, altered cytokine levels might not control autocrine regulation
 344 of astrocytogenesis, or that other molecular mechanisms known to modulate gliogenesis
 345 are not altered in this context. On the other hand, a reduction in β -III-tubulin positive cell
 346 numbers was detected, without affecting apoptotic neuronal population, suggesting
 347 inhibition of neurogenesis. This finding is corroborated by the recent demonstration that *T.*
 348 *gondii* infection impairs neuron generation from C17.2 neural stem cell line *in vitro* (Gan et
 349 al., 2016; Zhang et al., 2017). However, it is possible that, in addition to *T. gondii* induced
 350 alterations of well-known molecular mechanisms that control neurogenesis during cortical
 351 development, such as Wnt/ β cat signaling (Gan et al., 2016; Zhang et al., 2017) and
 352 neuronal differentiation transcription factors, such as Fabp7/BLBP, Sox2, Tacc3 Eya1,
 353 Sox2, and Tnfrsf12a genes (Xiao et al., 2012), altered levels of IL-6, TGF- β 1 and other, still
 354 unidentified cytokines, might exert an autocrine effect on the neurogenic potential of RG
 355 cells. Although *T. gondii* infection decreased the number of Nestin/BLBP and β -III-tubulin
 356 positive cells and did not alter GFAP cells numbers, overall cell composition percentages
 357 induced an increase in an unidentified cell population, suggesting that RG differentiation
 358 might favor the appearance of other cell types. Thus, since the literature lacks a more
 359 detailed investigation regarding the impact of congenital transmission of *T. gondii* in
 360 cerebral cortex embryonic development *in vivo*, it is essential to address how neurogenesis
 361 and/or gliogenesis are affected during CT in the developing brain.

362

363 **4.2) Impacts of *T. gondii* infection on RG potential to control endothelial** 364 **barrier properties.**

365 Vascular development by angiogenesis, in addition to blood vessel stability and
 366 function, result from a fine-tuned control of pro- and anti-angiogenic molecules
 367 produced by endothelial and neighboring cells, as well as environmental cues

(Carmeliet and Jain, 2000). In the last few years, RG have been pointed out as an essential cellular and molecular scaffold for blood vessel formation and vascular stability acquisition during cerebral cortex development (Ma et al., 2013; Errede et al., 2014; Hirota et al., 2015; Siqueira et al., 2017). Herein, we demonstrate that RG-CM treatment of endothelial cells greatly increases tight junction ZO-1 protein levels and organization, suggesting that RG-secreted factors promote microvascular barrier formation. Vascular stability and barrier properties are essential features that allow the controlled transport of nutrients and other substances across the BBB (Abbott, 2005; Ben-Zvi et al., 2014). Several molecular mechanisms were shown to promote the expression of tight junction proteins Claudin-5, Occludin and ZO-1 in endothelial cells, thus leading to the formation of the BBB, including activation of the TGF- β 1 signaling pathway, PDGFR/PDGR-B interaction and Wnt/ β catenin (Alvarez et al., 2011; Baeten and Akassoglou, 2011; Zhao et al., 2014; Zhao et al., 2015). In this context, *T. gondii* infection may indirectly deregulate signaling pathways critical in controlling vessel stability by (i) affecting RG potential concerning mediation of BBB formation or (ii) disrupting tight junction proteins expression and organization directly in endothelial cells. Increased BBB disruption and permeability have been recently correlated to elevated levels of the pro-inflammatory cytokine IL-6 in the cerebrospinal fluid of human adult individuals affected by neuromyelitis optica and neuropsychiatric systemic lupus erythematosus, and in a rat model of psychosocial stress induction (Uchida et al., 2017; Asano et al., 2017; Schiavone et al., 2017).

Pro-inflammatory cytokines, such as IL-6, have been previously reported to promote BBB dysfunction in several neurodegenerative disease contexts, such as Alzheimer's, Parkinson's and Multiple sclerosis, as well as CNS ischemia and infectious diseases, being a potential neuroinflammation establishment mechanism (Kempuraj et al., 2016; Rochfort et al., 2016). Stimulation of endothelial human brain cells (HCECs) with IL-6 was shown to induce VEGF synthesis and release, promoting angiogenesis, alongside increased expression of matrix metalloproteinase 9 (MMP9) (Yao et al., 2006). Increased MMPs

396 levels in different brain injury models were associated with degradation of the endothelial
397 basement membrane and enhanced tyrosine phosphorylation of tight junction proteins,
398 triggering protein redistribution, changes in adhesive properties between endothelial cells,
399 and TEER reduction, resulting in increased permeability (Stamatovic et al., 2008).

400 Although the roles of IL-6 have been pointed as essential to endothelial function,
401 angiogenesis and blood vessel stability have been classically described as depending on
402 anti-inflammatory TGF- β 1 cytokine signaling in the embryonic and adult brain (Dohgu et al.,
403 2004; Lebrin et al., 2005; Holderfield and Hughes, 2008; Arnold et al., 2014; Hellbach et al.,
404 2014; Siqueira et al., 2017). TGF- β 1 is a multifunctional cytokine that controls multiple
405 physiological and pathological events, such as embryogenesis, immune response, ECM
406 synthesis, cell differentiation and cell-cycle control in several tissues (Massague, 1998;
407 Massague and Gomis, 2006). TGF- β 1 in the CNS has been reported to play a key role in
408 neuronal generation, survival and migration (Brionne et al., 2003; Miller, 2003; Esposito et
409 al., 2005; Stipursky et al., 2012), glial differentiation (Sousa Vde et al., 2004; Romao et al.,
410 2008; Stipursky et al., 2014), and synapse formation (Diniz et al., 2012; Diniz et al., 2014).
411 More recently, our group demonstrated that TGF- β 1 secreted from RG cells induces
412 angiogenesis in the developing cerebral cortex (Siqueira et al., 2017). Herein, we observed
413 that CM from infected RG cells contains lower TGF- β 1 levels compared to uninfected cells.
414 Loss of the active form of TGF- β 1 cytokine, mutation of the *Tgfb1* gene or even deletion of
415 *Tgfr2* or *Alk5/Tgfr1* genes in endothelial cells of the embryonic forebrain have been shown
416 to promote excessive vascular sprouting, branching and induce cerebral hemorrhage
417 (Arnold et al., 2014). Furthermore, TGF- β 1 is known to promote tight junction proteins and
418 P-glycoprotein transporter expression in brain endothelial cells (Dohgu et al., 2004), induce
419 endothelial barrier properties, such as γ -glutamyl-transferase (GGT) expression, mediated
420 by astrocyte secretion (Garcia et al., 2004), and TGF- β signaling is involved in later stages
421 of blood vessel development, such as the induction of maturation and stability maintenance
422 mediating the interaction between endothelial and mural cells (Lebrin et al., 2005).

Here we demonstrated that Inf-RG-CM presented increased amounts of IL-6 and significantly less TGF- β 1, compared to control RG-CM. Evidence shows that disruption of endothelial interactions with neurovascular unit or low levels of TGF- β 1 leads to abnormal distribution of junctional proteins and increased vascular permeability (Garcia et al., 2004; Dohgu et al., 2005; Winkler et al., 2011). In the BBB, TGF- β 1 secretion by astrocytes has been demonstrated as essential for maintaining brain vasculature stability and inhibiting or decreasing leukocyte transmigration across the endothelium (Fabry et al., 1995; Alvarez et al., 2013). Since mature BBB astrocytes are the main source of TGF- β 1, and RG cells also secrete TGF- β 1, which we demonstrated as promoting RG-astrocyte differentiation (Stipursky and Gomes, 2007; Stipursky et al., 2012, 2014), it is possible that, in our infection model, reduced levels of RG-derived TGF- β 1, and possibly elevated levels of IL-6 proinflammatory cytokine, might impair endothelial ZO-1 tight junction organization and β -catenin association in adherens junctions.

By adding TGF- β 1 to the Inf-RG-CM, there was a complete rescue of endothelial ZO-1 protein levels, suggesting that *T. gondii* infection impairs TGF- β 1 expression/secretion, or both, by RG cells.

In this context, alteration of RG secretome by *T. gondii* infection, may act as underlying mechanisms of disruption of endothelial cell barrier properties. However, specific downstream angiogenesis and vascular maturation molecular targets have not yet been identified.

Herein, β -catenin has been pointed out as a potential target for RG-endothelial dysfunctional interaction. The Wnt/ β -catenin pathway has been extensively investigated and demonstrated as exerting critical roles on vascular development and maturation in the developing cerebral cortex and maintenance of BBB in adult brain (Liebner et al., 2008; Daneman et al., 2009; Ma et al., 2013; Engelhardt and Liebner, 2014). β -catenin, the canonical downstream mediator of Wnt signaling, associates with classic cadherins in adherens junctions and to α -catenin, that mediates its association with the actin

450 cytoskeleton. In endothelial cells, β -catenin is constitutively bound to VE-cadherin and when
451 β -catenin is free in cytoplasm, it is rapidly inactivated by phosphorylation and ubiquitination
452 by a protein complex that includes axin and adenomatous polyposis coli (APC). Upon
453 downregulation of VE-cadherin expression or Wnt signaling activation in endothelial cells,
454 β -catenin translocates to the nucleus to modulate gene expression, acting as a co-
455 transcription factor together with lymphoid enhancer factor/T-cell factor (Lef/TCF), Forkhead
456 box protein O1 (FoxO1), hypoxia-inducible factor (HIF), Smads and others, mediating
457 cellular responses such as cell cycle, apoptosis, cell differentiation and cell-cell
458 communication (Klaus and Birchmeier, 2008; Giannotta et al., 2013).

459 A previous report demonstrated that VE-cadherin phosphorylation prevents p120 and
460 β -catenin binding, triggering destabilization of adherens junctions, maintaining cells in a
461 mesenchymal state (Potter et al., 2005).

462 Endothelial cells adherens and tight junctions lay in close proximity to neighbor cells,
463 both mediating membrane adhesion and limiting paracellular permeability. Although
464 adherens and tight junctions are formed by distinct structural proteins, with specific binding
465 affinities, the assembly of tight junctions has been demonstrated as coupled with the
466 formation of adherens junctions. Physical linkages between these junctional structures can
467 be mediated by a multistep process that involves α -, β -catenins, ZO-1 and afadin proteins
468 interactions, initiating with adherens junctions protein clustering and structural organization
469 on cell membranes that later recruit and allow tight junctional machinery to assemble (for
470 revision Campbell et al., 2017). In fact, β -catenin/FoxO1 transcription factor complex was
471 demonstrated to repress Claudin-5 tight junction gene expression (Taddei et al., 2008). Ma
472 and colleagues (2013) demonstrated that Wnt/ β -catenin signaling activation can mediate
473 RG-endothelial interaction through transcriptionally induction of MMP2/MMP9 in endothelial
474 cells, which was correlated to decreased vessel stability and increased endothelial
475 proliferation in the developing cerebral cortex. Accordingly, increased MMPs levels were
476 found in astrocyte cultures (Lu and Lai, 2013) and in the sera of pregnant women infected
477 with *T. gondii* (Wang and Lai, 2013), suggesting that Wnt/ β -catenin signaling may modulate

478 junction protein levels expression and organization and/or turnover through multiple
479 mechanisms. Thus, in our context, *T. gondii* infection effects might exert critical function in
480 triggering endothelial junction dismantling, alongside β -catenin dissociation from cell-cell
481 contacts.

482 Together, our results suggest that *T. gondii* deregulates RG cells proliferation,
483 neurogenesis potential and secretory profile, with decreased TGF- β 1 and, to a less extent,
484 increase in IL-6 levels. In addition, the potential of RG cells to modulate endothelial cell
485 function is also affected by *T. gondii* infection, resulting in deficient organization of tight
486 junction protein ZO-1 and junction associated β -catenin, reduced TEER, leading to impaired
487 endothelial stabilization and loss of barrier properties. In a CT context, alterations in the
488 RG cell differentiation potential and in RG-endothelial cell interactions may be critical to the
489 reduced numbers of neurons generated during cortical development and dysfunctional BBB
490 formation, which would directly contribute to the establishment of the microcephaly
491 phenotype. Although RG-endothelial interactions are critical to promote vascular
492 development and BBB formation, the specific molecular mechanisms disrupted by *T. gondii*
493 infection in such interactions are not known. Thus, an improved description of the signaling
494 pathways involved in such events might contribute to the development of therapeutic
495 approaches to rescue or protect neural stem cells functions and vascular development, thus
496 preventing the clinical manifestations observed in CT.

497

498 **5) ACKNOWLEDGEMENTS**

499 We thank Dr. Flávia Carvalho Alcantara Gomes for providing equipment, laboratory
500 facility and some reagents; Marcelo Meloni, Adiel Batista do Nascimento and Sandra Maria
501 Oliveira Souza for technical assistance and Dr. José Morgado Diaz (INCA) and Dr. Luzia
502 Maria de Oliveira Pinto (IOC, Fiocruz) for the use of their MilliCell equipment.

503

504 **6) AUTHOR CONTRIBUTIONS STATEMENT**

505   DA performed bEnd.3 cultures, infection and TEER experiments. ACM performed
506 bEnd.3, treatments, immunocytochemistry quantifications and radial glia
507 immunocytochemistry quantifications. MS performed radial glia and bEnd.3
508 immunocytochemistry. CMC and MCW performed CBA and ELISA cytokines analysis,
509 respectively. JS performed radial glia cultures, bEnd.3 immunocytochemistry, TGF- β 1
510 ELISA and wrote the first draft of the manuscript. HSB discussed the experimental design
511 and data interpretation regarding *T. gondii* infection, provided equipment, laboratory facility
512 and some reagents. DA and JS equally contributed in the design of most of the
513 experiments. All authors contributed to manuscript revision, read and approved the
514 submitted version.

788 FIGURES LEGENDS

789

790 **Figure 1. *T. gondii* infection decreases Radial glia cell proliferation and** 791 **neurogenic potential.**

792 Infection of RG cells cultures with *T. gondii* tachyzoites for 24 h significantly
793 decreased the number of Nestin/BLBP double labeled cells number, compared with control
794 (A-C) which was accompanied by reduced numbers of proliferative Ki67/Nestin positive
795 cells compared with control uninfected cells (D-F). A significant decrease in generation of
796 β -III-tubulin positive neuron numbers was induced by *T. gondii* infection, when compared
797 with control (G-I). RG differentiation into GFAP positive astrocytes was not affected by *T.*
798 *gondii* infection when compared to controls (J-L). *T. gondii* infection induced significant
799 changes in the percentage of cell composition in RG cultures compared to controls (M).
800 *P=0.0423, **P=0.0019, ***P=0.0001 versus controls, unpaired *t* test.

801

802 **Figure 2. Conditioned medium from *T. gondii*-infected Radial glia decreases ZO-** 803 **1/ β -catenin proteins organization and impairs barrier properties of brain**

804 **microvascular endothelial cells.** Murine brain endothelial cells (bEnd.3) were incubated
805 for 24h with cultivation medium (Control), conditioned medium derived from uninfected RG
806 cultures (RG-CM) or conditioned medium derived from *T. gondii*-infected RG cultures (Inf-
807 RG-CM). ZO-1 tight junction adapter protein was found mainly distributed along adjacent
808 cell membranes of confluent control cultures (A). Addition of RG-CM to endothelial
809 monolayers significantly increased the levels of ZO-1 proteins on cells surfaces (B, E).
810 bEnd.3 cells incubated with Inf-RG-CM (C, E) presented reduced levels of ZO-1
811 immunoreactivity, when compared with controls (A-E). Tight junction organization index in
812 cell-cell contact regions (TiJOR) was also increased by addition RG-CM, when compared
813 with control cultures, and significantly disrupted by Inf-RG-CM presenting as discontinuous
814 ZO-1 labeling, when compared with RG-CM-treated cultures (F). Transendothelial electrical
815 resistance (TEER) was significantly increased by RG-CM when compared to all conditions.
816 Inf-RG-CM treatment impaired RG potential to induce TEER by reducing electrical
817 resistance on bEnd.3 cells below control levels (G). In Control cultures β -catenin was found
818 associated with cell-cell junctional contacts, similar to ZO-1 tight junction distribution (H, K,
819 N). Addition of RG-CM to endothelial monolayers enhanced β -catenin immunoreactivity and
820 similar to ZO-1 protein on cells contacts regions (I, L, O). bEnd.3 cells incubated with Inf-
821 RG-CM presented reduced immunoreactivity for β -catenin similar to ZO-1, concomitant with
822 junctions disorganization (J, M, P) when compared with controls (A-C). β -catenin
823 distribution in infected cells were mainly displaced to intracellular parasites *P=0.03,
824 **P=0.0001, one-way ANOVA with Bonferroni post-test.

825
826
827 **Figure 3. *T. gondii* infection alters the levels of secreted cytokines by Radial**
828 **glia cells.** Conditioned medium from uninfected RG cultures (RG-CM) and from cultures
829 infected with *T. gondii* tachyzoites for 24 h (Inf-RG-CM), were subjected to Cytokine Bead
830 Array (CBA) and ELISA assays to measure the levels of pro and anti-inflammatory secreted
831 cytokines. CBA detected augmented levels of IL-6 and ELISA revealed decreased TGF- β 1

832 levels (A) in Inf-RG-CM, compared with RG-CM. Addition of TGF- β 1 (19=0ng/mL) to Inf-
833 RG-CM significantly rescued the levels of ZO-1 labeling intensity, similar to addition of TGF-
834 β 1 alone to bEnd.3 cells, when compared to RG-CM. **p=0.0001, *p=0.036, one-way
835 ANOVA with Bonferroni post-test.

836 .

837 **Supplementary figure 1. Identification of *T. gondii* tachyzoites in infected cells.**

838 RG cultures were infected with *T. gondii* tachyzoites for 24h and labelled with DAPI to
839 identify host cell nucleus and parasite DNA (blue). Uninfected RG cultures labeled with
840 DAPI and Nestin (red) (A, B). Infected RG cells showing host and tachyzoites DNA in the
841 cytoplasm (C, D, arrows), high magnification of tachyzoites in infected cells (D', D'').

842

843 **Supplementary figure 2. *T. gondii* infection does not affect RG and neuronal cell**

844 **death.** RG cultures were infected with *T. gondii* tachyzoites for 2h and and labelled with
845 neuronal marker (bTubulin), RG marker (Nestin) and apoptotic cell marker (cleaved-
846 Caspase 3), No statistic differences in the percentage of β -tubulinIII/Caspase3 (A, C) and
847 Nestin/Caspase3 (B, D) double positive cells were observed. Quantification of total DAPI-
848 labeled nucleus per microscopical field in uninfected and infected RG cultures revealed no
849 significant difference in total cells number in both conditions (E). P>0.05, unpaired *t*-test.
