34 Highlight: NOS-mediated early NO burst plays an important role in alleviating
35 oxidative damage induced by water stress, by enhancing the antioxidant defenses in
36 roots supplemented with NH_4^+

37

38 Abstract

39 Ammonium (NH_4^+) can enhance rice drought tolerance in comparison to nitrate
40 (NO_3^-). The mechanism underpinning this relationship was investigated based on the
41 time-dependent nitric oxide (NO) production and its protective role in oxidative stress
42 of NH_4^+ / NO_3^- -supplied rice under drought. An early burst of NO was induced by
43 drought 3h after root NH_4^+ treatment but not after NO_3^- treatment. Root oxidative
44 damage induced by drought was significantly higher in NO_3^- than in NH_4^+ -treatment
45 due to its reactive oxygen species accumulation. Inducing NO production by applying
46 NO donor 3h after NO_3^- treatment alleviated the oxidative damage, while inhibiting
47 the early NO burst increased root oxidative damage in NH_4^+ treatment. Application of
48 nitric oxide synthase (NOS) inhibitor N(G)-nitro-L-arginine methyl ester (L-NAME)
49 completely suppressed NO synthesis in roots 3h after NH_4^+ treatment and aggravated
50 drought-induced oxidative damage, indicating the aggravation of oxidative damage
51 might have resulted from changes in NOS-mediated early NO burst. Drought also
52 increased root antioxidant enzymes activities, which were further induced by NO
53 donor but repressed by NO scavenger and NOS inhibitor in NH_4^+ -treated roots. Thus,
54 the NOS-mediated early NO burst plays an important role in alleviating oxidative
55 damage induced by drought by enhancing antioxidant defenses in NH_4^+ -supplied rice
56 roots.

65 reactive oxygen species (ROS), sodium nitroprusside (SNP), superoxide dismutase
66 (SOD).

67 Introduction

68 As human population and global climate change increase, drought stress is
69 becoming a major abiotic factor limiting crop growth and yield. Plants have evolved
70 several strategies to contend with water stress. These include morphological,
71

72 physiological, and molecular adaptations (Bogeat-Triboulot *et al.*, 2007; Guo *et al.*,
73 2007; Slewinski, 2012). Nitric oxide (NO) is an important signaling molecule in
74 various physiological functions like seed germination, floral transition, stomatal
75 movement, leaf senescence, and yield development, and it has gained increasing
76 attention since the 1980s (Neill *et al.*, 2003; Wilson *et al.*, 2007; Simontacchi *et al.*,
77 2015). Certain plant responses and adaptations to abiotic stresses involve NO, and
78 sufficient data indicate that NO mediates plant responses to various stimuli including
79 drought (Mata and Lamattina, 2001), salt (Zhao *et al.*, 2007), and metal toxicity
80 (Gonzalez *et al.*, 2012) stresses, thereby enhancing plant stress tolerance and survival.

81 Water deficits significantly increase NO production in plants (Signorelli *et al.*,
82 2013; Planchet *et al.*, 2014). As a free radical, NO can form various reactive nitrogen
83 species (RNS) such as peroxynitrite (ONOO⁻), nitrogen dioxide (NO₂),
84 dinitrogen trioxide (N₂O₃) and S-nitrosoglutathione (GSNO), which are involved in
85 many physiological functions of plants (del Rio, 2015), indicating that NO and
86 NO-derived molecules take part in inorganic nitrogen (N) metabolism. A combination
87 of transgenic technology and pharmacological analysis have indicated that NO
88 induces antioxidant activity and alleviates water stress in plants in several ways: 1) It
89 limits reactive oxygen species (ROS) accumulation and ROS-induced cytotoxic
90 activity by inhibiting the ROS-producer NADPH oxidase via S-nitrosylation (Fan *et*
91 *al.*, 2012); 2) It functions as an antioxidant and reacts with ROS (e.g. O₂⁻) to generate
92 transient ONOO⁻, which is then scavenged by other cellular processes (del Rio, 2015);
93 3) It induces the expression of genes coding for antioxidant enzymes, such as
94 superoxide dismutase (SOD), ascorbate peroxidase (APX), and glutathione reductase
95 (GR), and may increase enzyme activity by posttranslational modifications thereby
96 reducing lipid peroxidation under water stress (Farooq *et al.*, 2009; Fan and Liu,
97 2012); 4) It helps maintaining high vacuolar concentrations of osmotically active
98 solutes and amino acids like proline (Verdoy *et al.*, 2006); and 5) It acts as a
99 downstream abscisic acid (ABA) signal molecule and participates in
100 “ABA-H₂O₂-NO-MAPK” signal transduction processes. It also increases plant
101 antioxidant ability (Zhang *et al.*, 2007). The accumulation of ROS in water-stressed
102 plants impairs the function of biochemical processes, damages organelles, and
103 ultimately results in cell death (Jiang and Zhang, 2002). Therefore, endogenous NO
104 production may enhance plant antioxidant capacity and help plant cells survive under
105 various types of stresses.

106 However, NO also has biphasic properties on plants. The duality of its effects
107 depends on stress duration and severity, and on the cell, tissue, and plants species
108 (Neill, 2007; Santisree *et al.*, 2015). At low concentration or early stage of abiotic
109 stress, NO participates in important functions in higher plants through its involvement
110 in physiological and stress-related processes (as described above).
111 Arasimowicz-Jelonek *et al.* (2009a, b) demonstrated that NO synthesis slightly
112 increased in roots subjected to <10 h water deficit, but significantly up-regulated after
113 prolonged (≥ 17 h) drought. Under severe or protracted longtime stress, NO
114 overproduction in plants can shift the cellular stress status from oxidative stress to
115 severe nitrification stress, finally damaging proteins, nucleic acids, and membranes
116 (Groß *et al.*, 2013; del Rio 2015). Protein tyrosine nitration is considered a good
117 marker to evaluate the process of nitrosative stress under various abiotic environments
118 (Corpas *et al.*, 2007, 2008). Excess NO can also act synergistically with ROS
119 resulting in nitro-oxidative stress and eliciting undesirable toxic effects in plant cells
120 (Signorelli *et al.*, 2013). Liao *et al.* (2012) and Sun *et al.* (2014) argued that the ability
121 of endogenous or exogenous NO production in plants to alleviate oxidant damage was
122 dose-dependent. Therefore, determining instantaneous plant NO content under
123 drought stress may not completely reflect the specific role of NO in drought tolerance.

124 In higher plants, nitrate reductase (NR) and nitric oxide synthase (NOS) are the
125 two key enzymes for NO production (Guo *et al.*, 2003; Neill *et al.*, 2003). Moreover,
126 NR-dependent NO production occurs in response to pathogen infection (Shi and Li,
127 2008), drought (Freschi *et al.*, 2010), and freezing (Zhao *et al.*, 2009).
128 Arasimowicz-Jelonek *et al.* (2009a, b) applied the NO donor sodium nitroprusside
129 (SNP) and GSNO to water-stressed cucumbers and demonstrated that both NR and
130 NOS participated in drought tolerance. Shi *et al.* (2014) reported that rat neuronal NO
131 synthase overexpression in rice plants increased their tolerance to drought stress, thus
132 demonstrating the importance of NOS-mediated NO production in water deficit
133 tolerance. Despite increasing knowledge on NO-mediated plant functions, NO origins
134 and signaling in response to prolonged stress and their regulation in plant drought
135 tolerance remain poorly understood.

136 Ammonium (NH_4^+) and nitrate (NO_3^-) are the two primary N sources for plants.
137 It is known that the negative effects of drought stress on plant development can be
138 more effectively alleviated by NH_4^+ than NO_3^- supplementation, as evaluated by plant
139 growth, physiological characteristics, and gene expression levels (Guo *et al.*, 2007,

Yang *et al.*, 2012; Ding *et al.*, 2015). NO has a key role in plant water stress acclimation and drought tolerance. Nevertheless, information on the dynamic changes in NO production and its role in drought acclimation in plants supplied with NO₃⁻ or NH₄⁺ during the early stages of water stress is scarce. In the present study, variations in endogenous NO production were monitored in roots supplied with this two N nutrition supplements during water stress. The specific role and origin of the endogenous NO produced were investigated using pharmacological methods. The present study revealed that an early NO burst is crucial for alleviating the water stress-induced oxidative damage through enhancement of antioxidant defenses in roots of NH₄⁺-supplied plants. Further analyses demonstrated that this early NO burst might be triggered by NOS-like enzymes.

151

152 **Materials and methods**

153 **Plant material and growth conditions**

154 Rice (*Oryza sativa* L. 'Zhongzheyu No. 1' *hybrid indica*) seedlings were grown
155 hydroponically in a greenhouse. Seeds were sterilized in 1% (v/v) sodium
156 hypochlorite solution. After germination, seeds were transferred to a 0.5 mmol L⁻¹
157 CaCl₂ solution (pH 5.5). Three days later, the seedlings were transferred to 1.5-L
158 black plastic pots containing a solution with the following composition: NH₄NO₃ (0.5
159 mM), NaH₂PO₄·2H₂O (0.18 mM), KCl (0.18 mM), CaCl₂(0.36 mM), MgSO₄·7H₂O
160 (0.6 mM), MnCl₂·4H₂O (9 μM), Na₂MoO₄·4H₂O (0.1 μM), H₃BO₃ (10 μM),
161 ZnSO₄·7H₂O (0.7 μM), CuSO₄ (0.3 μM), and FeSO₄·7H₂O-EDTA (20 μM). All
162 experiments were performed in a controlled growth room under the following
163 conditions: 14/10 h light/dark photoperiod, 400 μmol m⁻² s⁻¹ light intensity, 28°C or
164 23°C during day or night, respectively, and 60% relative humidity. The solution pH
165 was adjusted to 5.5 with 5 mM 2-(N-Morpholino)ethanesulfonic acid (MES). The
166 solution was replaced every 3 days.

167 After 6 days, seedlings of similar size were cultivated under one of the following
168 treatments: 1 mM NO₃⁻, 1 mM NO₃⁻ + 10% polyethylene glycol (PEG-6000), 1 mM
169 NH₄⁺, or 1 mM NH₄⁺ + 10% PEG-6000. Water stress was induced by adding 10%
170 PEG-6000. Eight treatments were performed in the NO donor (i.e., SNP) experiments:
171 NH₄⁺, NH₄⁺ + SNP, NH₄⁺ + PEG-6000, NH₄⁺ + PEG-6000 + SNP, NO₃⁻, NO₃⁻ + SNP,
172 NO₃⁻ + PEG-6000, and NO₃⁻ + PEG-6000 + SNP. The final SNP concentration was 20
173 μM. For each N nutrition experiment, treatments receiving sufficient water were

174 defined as control (CK) treatments.

175 For the NO
176 scavenger 2-(4-carboxyphenyl)-4,4,5,5-tetramethylimidazoline-1-oxyl-3-oxide
177 (c-PTIO, 100 μ M) experiment, rice seedlings supplied with 1 mM NO_3^- or 1 mM
178 NH_4^+ solution were pretreated with c-PTIO for 3 h and then given sufficient water
179 (CK) or subjected to water stress for 24 h under the same conditions as those
180 described above.

181 To investigate the effects of the NO biosynthesis inhibitors, rice seedlings
182 supplied with 1 mM NO_3^- or 1 mM NH_4^+ solution were pretreated with the NO
183 scavenger, tungstate NR inhibitor (100 μ M), or NOS inhibitor [Nx-Nitro-*L*-arginine
184 methyl ester hydrochloride (L-NAME); 100 μ M] for 3 h, and then given sufficient
185 water (CK) or subjected to water stress for 24 h under the same conditions as
186 described above. There were eight treatments for each N nutrition: Tungstate,
187 L-NAME, Tungstate + SNP, PEG-6000 + Tungstate, PEG-6000 + Tungstate + SNP,
188 L-NAME + SNP, PEG-6000 + L-NAME, and PEG-6000 + L-NAME + SNP.

189

190 **Determination of NO and ONOO⁻ contents**

191 The 4-amino-5-methylamino-2',7'-difluorofluorescein diacetate (DAF-FM DA)
192 probe was used to determine endogenous root NO levels (Sun *et al.*, 2014). Root tips
193 (1 cm) were incubated with 10 μ M DAF-FM DA in the dark for 30 min, washed 3 $\times$
194 with 20 mM HEPES-KOH (pH 7.4) to remove excess fluorescence, and then observed
195 and photographed under a Nikon Eclipse 80i fluorescence microscope (Nikon, Tokyo,
196 Japan; EX 460-500, DM 505, BA 510-560). The relative fluorescence intensity was
197 measured with Photoshop v. 7.0 (Adobe Systems, Mountain View, CA, USA).

198 Root endogenous ONOO⁻ was determined using the aminophenylfluorescein
199 (APF) probe method. Root tips were incubated with 10 μ M APF dissolved in 10 mM
200 Tris-HCl (pH 7.4) in the dark for 60 min, and then washed 3 $\times$ with 10 mM Tris-HCl.
201 Fluorescence images and relative fluorescence intensities were analyzed as described
202 above for NO.

203

204 **Histochemical analyses**

205 Lipid peroxidation and root cell death were histochemically detected with
206 Schiff's reagent and Evans blue (Yamamoto *et al.*, 2001). Root tips were incubated in
207 Schiff's reagent for 20 min and washed by three consecutive immersions in 0.5% (w/v)

208 K_2O_3S solution. A red/purple endpoint indicated the presence of aldehydes generated
209 by lipid peroxidation. Roots were also washed by performing three serial immersions
210 in distilled water, then incubated in 0.25% (w/v) Evans blue for 15 min, and finally
211 washed 3× with distilled water. Roots stained with Schiff's reagent and Evans blue
212 were immediately photographed under a Leica S6E stereomicroscope (Leica, Solms,
213 Germany).

214 The oxidative damage level, specifically expressed as membrane lipid
215 peroxidation and protein oxidative damage, were estimated by measuring the
216 concentrations of malondialdehyde (MDA) and carbonyl group with
217 2,4-dinitrophenylhydrazine (DNPH) according to the methods described in Velikova
218 *et al.* (2000).

219

220 **Determination of ROS contents**

221 Root O_2^- content was estimated using the method described in Liu *et al.* (2007)
222 with some modifications: about 0.15 g fresh root was powdered with 2 mL of 65 mM
223 phosphate buffer saline (PBS, pH 7.8) in a pre-cooled mortar, and centrifuged at 5,000
224 × g for 10 min at 4 °C. Then, 0.9 mL of 65 mM PBS (pH 7.8) and 0.1 mL of 10 mM
225 hydroxylammonium chloride were added to 1 mL of the root extract supernatant,
226 thoroughly mixed, and left to react for 25 min. After this period, 1 mL of 1% (w/v)
227 sulfanilamide and 1 mL of 0.02% (w/v)
228 *N*-(1-naphthyl)-ethylenediaminedihydrochloride were added to 1 mL of root extract
229 solution and left to react for 30 min. Absorbance was then measured at 540 nm.

230 Root H_2O_2 content was determined by the photocolometric method: ~0.15 g
231 fresh root was powdered with 2 mL acetone in a pre-cooled mortar, and centrifuged at
232 5,000 × g for 10 min at 4 °C. Then, 0.1 mL of 5% (w/v) $TiSO_4$ and 0.1 mL pre-cooled
233 ammonium hydroxide were added to 1 mL of the root extract supernatant, which was
234 re-centrifuged at 5,000 × g for 10 min. The supernatant was discarded and the
235 sediment was re-dissolved in 4 mL of 2 M H_2SO_4 . The absorbance of the root extract
236 solution was measured at 415 nm (Wang *et al.*, 2010).

237 Root $OH^\cdot$ was analyzed by the methods described in Liu *et al.* (2010): ~0.1 g
238 fresh root was powdered with 3 mL of 50 mM PBS (pH 7.0) in a mortar, and
239 centrifuged at 10,000 × g for 10 min at 4 °C. Then, 1.0 mL of 25 mM PBS (pH 7.0)
240 containing 5 mM 2-deoxy-*D*-ribose and 0.2 mM NADH were added to 1 mL of the
241 root extract supernatant, completely blended, and left to react for 60 min at 35°C in

the dark. Following this incubation, 1 mL of 1% (w/v) thiobarbituric acid and 1 mL glacial acetic acid were added to the filtrate. The mixture was heated to 100°C for 30 min and then placed on ice for 20 min. The absorbance of the root extract solution was then measured at 532 nm, and the OH⁻ content was inferred from the production of MDA.

Determination of enzyme activities

Fresh rice root samples (0.5 g) were homogenized in 5 mL of 10 mM phosphate buffer (pH 7.0) containing 4% (w/v) polyvinylpyrrolidone and 1 mM ethylenediaminetetraacetic acid. The supernatant was used as crude enzyme solution and collected by centrifugation at 12,000 × *g* for 15 min at 4°C. The activities of SOD, catalase (CAT), APX, and peroxidase (POD) were estimated using the photolorimetric methods described in Jiang and Zhang (2002) and Sachadyn-Krol *et al.* (2016).

Root NR and NOS activities were assayed using the methods described in Scheible *et al.* (1997) and Lin *et al.* (2012), with some modifications. Briefly, total protein was extracted using a buffer containing 100 mM HEPES-KOH (pH 7.5), 1 mM EDTA, 10% (v/v) glycerol, 5 mM DTT, 0.5 mM phenylmethylsulfonyl fluoride, 0.1% Triton X-100 (v/v), 1% PVP, and 20 μM FAD. The supernatant was collected by centrifugation at 12,000 × *g* for 20 min at 4°C, and then used to determine the NR and NOS activities at 520 nm and 340 nm, respectively.

Determination of arginine and citrulline

Arginine and citrulline contents were estimated using the method described in Salazar *et al.* (2012). Briefly, 1.0 g root samples were frozen in liquid N₂ and extracted with 4 mL 80% (v/v) methanol, and then centrifuged at 10,000 × *g* for 5 min at 4 °C. The supernatant was then used in derivatization and reaction processes. Serial concentrations of amino acid standards were prepared as described above for the derivatizing reagent, and the derivatizing samples were used to determine the arginine and citrulline contents using liquid chromatography/electrospray ionization tandem mass spectroscopy(LC-ESI-MS).

Statistical analyses

All experiments conducted in this study were performed in triplicate, at least. All

275 data, expressed as means $\pm$ standard error (SE), were processed in SPSS v. 13.0 (IBM
276 Corp., Armonk, NY, USA). The Least Significant Difference (LSD) test was used to
277 determine statistical significant differences among the treatments ($P < 0.05$). Figures
278 were drawn in Origin v. 8.0 (OriginLab Corporation, Northampton, MA, USA).

279

280 **Results**

281 **Plant growth and physiological characteristics**

282 Growth- and physiology-related parameters, such as biomass, photosynthesis rate
283 (P_n), and root N uptake rate in rice seedlings supplied with different N sources were
284 negatively and differently influenced by the 21 days water stress (Supplementary Fig.
285 S1a-f). While there were significant decreases in the biomass of NO_3^- -supplied plants
286 (62.1% and 52.2% reductions in shoot and total biomass, respectively)
287 (Supplementary Fig. S1a, c), biomass accumulation was not significantly affected in
288 NH_4^+ -supplied plants, in relation to CK plants. Water stress reduced P_n in the leaves
289 of NO_3^- -treated plants by 40.4% ($P < 0.05$) but that of NH_4^+ -treated plants was only
290 reduced by 17.3% (Supplementary Fig. S1d) in relation to CK plants. Thus,
291 NH_4^+ -supplied rice seedlings can alleviate PEG-induced drought stress more
292 effectively than NO_3^- -supplied rice seedlings.

293

294 **Root endogenous NO production and histochemical analyses of oxidative damage**

295 To investigate whether NO participates in water stress acclimation, endogenous
296 NO levels in the roots were monitored with the NO-specific fluorescent probe
297 DAF-FM DA. Significant differences in endogenous NO production were observed in
298 roots after 48 h of water stress (Fig. 1a). In CK plants, NO production was relatively
299 stable and varied little between the two N treatments. In contrast, water stress
300 significantly induced endogenous NO production 3 h after the roots received NH_4^+ .
301 However, endogenous NO gradually increased only after 6 h in the NO_3^- treatment.
302 Relative fluorescence indicated a significant early burst of NO at 3 h of water stress in
303 the NH_4^+ treatment relative to the control. The NO level in the seedlings treated with
304 NH_4^+ was 2.92 $\times$ higher than that of NO_3^- -treated plants. Nevertheless, NO in the
305 NO_3^- -treated seedlings was 2.72 $\times$ higher than in NH_4^+ -treated plants after 24 h of
306 water stress (Fig. 1b).

307 Histochemical visualization by Schiff's reagent and Evans blue staining showed
308 that water stress caused severe oxidative damage to the plasma membrane and cell

309 death in the roots of the plants receiving NO_3^- , whereas the damage was far less
310 pronounced in the seedlings given NH_4^+ (Fig. 1c, d). The following analysis of the
311 MDA and carbonyl concentrations also confirmed that water stress induced more
312 severe lipid peroxidation in the roots of NO_3^- -treated than in the roots of NH_4^+ -treated
313 seedlings.

314

315 **Effects of the NO donor on root NO production and oxidative damage**

316 To determine the roles of NO in water stress tolerance, the NO donor SNP was
317 used to simulate NO production. Pre-experimentation with various SNP
318 concentrations (0-100 μM) was performed to quantify the efficacy of SNP against root
319 oxidative damage. As shown in Supplementary Fig. S2, root oxidative damage
320 induced by water stress was significantly alleviated by ≤ 20 μM SNP. However, the
321 remedial effect of SNP on root oxidative damage was reversed at higher application
322 doses (≥ 40 μM), suggesting that high SNP or NO contents are toxic to root growth.
323 Therefore, 20 μM SNP was used in the NO donor experiments conducted in the
324 present study. After 3 h of water stress, SNP application significantly increased root
325 NO fluorescence intensity for both N treatments. At 3 h, the NO production levels
326 were $\sim 2.05\times$ and $3.85\times$ higher in the SNP-treated roots of the seedlings receiving
327 NH_4^+ and NO_3^- , respectively, than in the roots of CK plants (Fig. 2a, b). However, this
328 phenomenon was not observed after 24 h of water stress.

329 After 3 h of water stress, ROS (O_2^- , H_2O_2 , and $\text{OH}^\cdot$) levels were increased in the
330 roots of both the NH_4^+ - and NO_3^- -treated seedlings in relation to that of CK seedlings.
331 Under water stress, the O_2^- , H_2O_2 , and $\text{OH}^\cdot$ in the roots given NH_4^+ and NO_3^- increased
332 by 78.1% and 107.3%, 28.3% and 47.8%, and 10.6% and 48.4%, respectively (Fig.
333 3a-c). After 3 h of water stress, root MDA and carbonyl were $\sim 1.28\times$ and $1.4\times$ higher
334 in the plants receiving NO_3^- than in CK plants, respectively. In turn, MDA and
335 carbonyl levels were significantly higher in the CK than in the plants given NH_4^+ (Fig.
336 4a, b). Water stress induced higher root ONOO^- in the NH_4^+ -treated plants than in the
337 NO_3^- -treated seedlings (Fig. 4d), and exogenous NO significantly reduced water
338 stress-induced ROS (O_2^- and H_2O_2) accumulation and oxidative damage (as reflected
339 by MDA and carbonyl) in both N treatments (Figs. 3, 4).

340 To determine whether the alleviation of water stress-induced oxidative damage
341 by SNP was related to NO production, the NO scavenger c-PTIO was applied to the
342 plants. After pretreatment with 100 μM c-PTIO for 3 h, alleviation of the water

343 stress-induced root oxidative damage by SNP was reversed (Fig. 4). Depletion of
344 endogenous NO by c-PTIO significantly aggravated root oxidative damage in the
345 NH_4^+ -treated plants but had no significant effect on the NO_3^- -treated plants (Fig. 4), in
346 relation to that observed in CK plants. Therefore, the water stress-induced early NO
347 burst observed in the NH_4^+ -treated plants alleviates root oxidative damage by
348 reducing ROS, such as O_2^- and H_2O_2 .

349

350 **Source of endogenous NO**

351 Endogenous plant NO production is mostly driven by NR and NOS. Water stress
352 increased NR activity in the NO_3^- -treated roots, and this activity was higher at 24 h
353 than it was at 3 h of water stress (Supplementary Fig. S3a). The activity of NOS was
354 also significantly elevated at 3 h of water stress, and significantly higher in the
355 NH_4^+ -treated than in the NO_3^- -treated roots (Supplementary Fig. S3b). In contrast,
356 water stress suppressed NOS activity in the NO_3^- -treated roots at 24 h. Tungstate and
357 L-NAME, which inhibit NR and NOS activities, respectively, were used to identify
358 the origin of the early NO burst in the NH_4^+ -treated roots. Although L-NAME
359 significantly inhibited endogenous NO production in the NH_4^+ -treated roots under 3 h
360 water stress, it had no significant effect in the NO_3^- -treated roots. At 24 h, the
361 tungstate and L-NAME applications suppressed NO production in the NO_3^- -treated
362 roots and tungstate had the stronger inhibitory effect. On the other hand, tungstate had
363 no significant effect on NO production in the NH_4^+ -treated roots (Fig. 5a, b).

364 The effect of SNP on the alleviation of water stress-induced root oxidative
365 damage was reversed after pretreatment with 100 μM c-PTIO for 3 h. Application of
366 the NOS inhibitor c-PTIO significantly aggravated water stress-induced oxidative
367 damage in the NH_4^+ -treated roots, and SNP application reversed the effect of the NOS
368 inhibitor but not that of the NR inhibitor (Fig. 5c, d). For the NO_3^- -treated roots, the
369 application of the NR inhibitor or NOS inhibitor had no significant effect on root
370 oxidative damage relative to the PEG (water stress) treatment.

371

372 **Activities of antioxidative enzymes and nitrate/nitrite and arginine/citrulline** 373 **metabolism**

374 Water stress significantly enhanced the activities of root antioxidant enzymes
375 CAT, SOD, APX, and POD by ~107% and 38%, 52% and 36%, 152% and 128%, and
376 45% and 37% in the NH_4^+ -treated roots and the NO_3^- -treated roots, respectively,

377 compared to the CK roots (Fig. 6). While SNP application further increased CAT,
378 SOD, and APX activities (Fig. 6a-c), these antioxidant enzymes were inhibited by the
379 application of the NO scavenger c-PTIO and by the NOS inhibitor L-NAME in the
380 NH_4^+ -treated roots under water stress.

381 As NR and NOS activities increased in the NO_3^- -treated roots, water stress
382 lowered the nitrate level in the NR pathway and the arginine level in the NOS
383 pathway (Supplementary Fig. S4a, b). Similarly, NR inhibitor and NOS inhibitor
384 applications enhanced root nitrate and arginine contents, respectively. In the
385 NH_4^+ -treated roots, water stress significantly decreased arginine level, indicating that
386 arginine metabolism was relatively high. In this treatment, the NR inhibitor had no
387 significant effect on root arginine content. On the other hand, the NOS inhibitor
388 suppressed arginine metabolism, and thus the NH_4^+ -treated roots had higher arginine
389 levels than CK roots (Supplementary Fig. S4c). These results indicate that the NO
390 production burst in the NH_4^+ -treated roots might originate from the NOS pathway.

391

392 Discussion

393 Ample experimental evidence has demonstrated that NO is involved in plant
394 abiotic stress (Neill *et al.*, 2003; Santisree *et al.*, 2015). However, to our knowledge,
395 no detailed study has been conducted to evaluate the role of NO in drought
396 acclimation in plants supplied with NO_3^- or NH_4^+ . In the present study, biomass, root
397 N uptake rate, and leaf photosynthesis were reduced relative to the control treatments
398 after 21 days of water stress (Supplementary Fig. S1). However, these reductions were
399 less severe for seedlings receiving NH_4^+ suggesting that NH_4^+ supplementation can
400 enhance drought tolerance in rice seedlings more effectively than NO_3^-
401 supplementation (Guo *et al.*, 2007; Li *et al.*, 2012). Our study also demonstrated that,
402 in the short term (48 h), endogenous NO production in response to water stress is
403 usually time-dependent, varying according to water stress duration. This finding is
404 consistent with those reported for other stressors (Planchet *et al.*, 2014; Sun *et al.*,
405 2014). Early NO bursts were induced at 3 h of water stress in the roots of
406 NH_4^+ -treated seedlings but not in the roots of NO_3^- -treated seedlings. Thus, there
407 might be significant differences between NH_4^+ -/ NO_3^- -supplied plants in terms of NO
408 signal-mediated drought tolerance. In addition, accumulation of ROS, such as O_2^- ,
409 OH^- , and H_2O_2 , and root oxidative damage were significantly lower in the
410 NH_4^+ -treated than in the NO_3^- -treated roots at 3 h of water stress. Because ROS

411 accumulation damages cells and their plasma membranes by inducing lipid
412 peroxidation (oxidative stress) (Jiang and Zhang, 2002), the early NO burst in
413 response to water stress observed in NH_4^+ -supplied seedlings might play a crucial role
414 in their antioxidant defense system and drought tolerance.

415 The role of the early NO burst in the water stress tolerance of
416 NH_4^+ -/ NO_3^- -supplied seedlings was confirmed using NO donors and scavengers. Our
417 study demonstrated that NO donors induced NO in the NO_3^- -treated roots at 3 h but
418 not at 24 h of water stress. Plant ROS accumulation and MDA and carbonyl levels
419 under water stress were significantly alleviated after the application of the NO donor
420 in both N treatments. Nevertheless, the levels of these substances were higher in the
421 NO_3^- -treated roots than in the NH_4^+ -treated roots. Therefore, the NO production
422 enhanced at 3 h by the exogenous NO donor can alleviate water stress-induced
423 oxidative damage in the NO_3^- -treated roots. On the other hand, elimination of the
424 early NO burst by NO scavengers like c-PTIO significantly aggravated water
425 stress-induced oxidative damage. These results provide direct evidence that the early
426 NO bursts plays a crucial role in drought tolerance in NH_4^+ -treated roots. Because
427 the NH_4^+ -supplied roots maintained a higher N uptake rate than NO_3^- -supplied roots
428 under water stress (Supplementary Fig. S1f), we hypothesized that the higher NH_4^+
429 uptake rate is beneficial for the NO early burst due to the NO production involved in
430 root N metabolism (Corpas *et al.*, 2008; del Rio, 2015). This NO burst can also be an
431 active adaptation mechanism of plants to abiotic stress as, in addition to drought stress,
432 it has been reported to occur repeatedly in plants challenged by pathogens
433 (Floryszak-Wieczorek *et al.*, 2007), metal toxicity (Gonzalez *et al.*, 2012; Sun *et al.*,
434 2014), and cold stress (Cantrel *et al.*, 2011).

435 Our study demonstrated that an early NO burst improves plant drought tolerance
436 by enhancing the antioxidant defense system of the root. Elevated plant antioxidant
437 enzyme activities and gene expression levels in response to water stress have been
438 widely demonstrated (Jiang and Zhang, 2002; Arasimowicz-Jelonek *et al.*, 2009a; Fan
439 and Liu, 2012). In the present study, the tips of the NO_3^- -treated roots presented more
440 serious water stress-induced oxidative damage (due to the excessive production of O_2^- ,
441 OH^- , and H_2O_2) than those of the NH_4^+ -treated roots (Figs. 1-3). In contrast,
442 NH_4^+ -supplied roots maintained relatively higher antioxidant enzyme (CAT, SOD, and
443 APX) activity levels to catalyze O_2^- and H_2O_2 decomposition (Fig. 3). It has been

demonstrated that there is significant crosstalk between NO and ROS in plants. The antioxidant function of NO was explained by its ability to reduce H₂O₂ and lipid peroxidation, and induce antioxidant gene expression and enzyme activity (Bogeat-Triboulot *et al.*, 2007; Farooq *et al.*, 2009). Our results showed that enhanced NO levels and antioxidant enzyme activities (CAT and SOD) were significantly and simultaneously increased after NO donor application in NO₃⁻-treated roots thereby reducing ROS concentration and oxidative damage. The early NO burst observed in NH₄⁺-treated roots can enhance antioxidant enzyme activity and ROS accumulation (O₂⁻, OH[·], and H₂O₂). These results were confirmed by subsequent experimentation in which the application of NO scavenger significantly suppressed SOD and CAT in NH₄⁺-treated roots. Thus, drought tolerance in the NH₄⁺-treated roots might be associated with the NO induced up-regulation of antioxidant enzymes and down-regulation of ROS accumulation.

Nitric oxide can also serve as a source of reactive nitrogen species (RNS). Over accumulation of RNS under abiotic stress can cause tyrosine nitration and inactivate proteins like CAT, manganese-dependent (Mn-)SOD, and GR (Clark *et al.*, 2000) as well as the peroxidative activity of cytochrome c (Batthyany *et al.*, 2005). Our results show that NO₃⁻-supplied plants had more severe oxidative damage and accumulated extremely high NO levels after 24 h of water stress. This latent NO production can be partially alleviated by replenishing the early NO burst at 3 h with SNP (Fig. 1). These results indicate that both ROS and RNS metabolism participate in the water stress response. High NO accumulation in the NO₃⁻-treated roots likely cause the nitrosative stress at 24 h, which also damaged root redox balance. A similar phenomenon was described in plants subjected to cold (Airaki *et al.*, 2012), salinity (Tanou *et al.*, 2012), and drought (Signorelli *et al.*, 2013) stresses. Because NO competes with oxygen for cytochrome c oxidase binding (Complex IV), it affects both the respiratory chain and oxidative phosphorylation (Millar and Day, 1996; Yamasaki *et al.*, 2001). Thus, under drought stress, the higher NO production in the NO₃⁻-treated roots than in the NH₄⁺-treated roots could aggravate respiratory inhibition and induce greater oxidative damage.

Our investigation suggests that the early NO burst in NH₄⁺-treated roots is mainly mediated NOS at the early stages of water stress. Nitrate reductase-mediated NO generation is known to occur under water deficit (Arasimowicz-Jelonek *et al.*, 2009b; Yu *et al.*, 2014). Drought-induced NO generation by NOS-like enzymes in

plants has also been demonstrated but this NO production pathway varies significantly with species, tissue type, and plant growth conditions (Corpas *et al.*, 2009; Liao *et al.*, 2012; Shi *et al.*, 2014). For the NH_4^+ -treated roots, both NOS activity and NO production increased simultaneously at 3h of water stress, whereas the application of the NOS inhibitor completely repressed NO synthesis at this time point. The NOS inhibitor also aggravated water stress-induced membrane lipid peroxidation and oxidative protein damage, indicating that some NOS associated proteins may play an important role in NO-mediated drought protective responses (Guo *et al.*, 2003; Zhao *et al.*, 2007). In contrast, the NR inhibitor did not significantly affect NO production or membrane lipid peroxidation. The aggravation of lipid peroxidation by L-NAME may have been the result of the alteration of the NOS-mediated early NO burst. In NO_3^- -treated roots, water stress enhanced NR activity significantly more than NOS activity at 24 h. However, separate NR inhibitor and NOS inhibitor applications only partially suppressed NO production. The NO produced by the NR pathway might therefore play an important role in later NO production (24 h), consistent with previous reports (Arasimowicz-Jelonek *et al.*, 2009a, b). Although several studies support the arginine-dependent NO production model in higher plants, the genes encoding NOS in such plants have not yet been identified (Zemojtel *et al.*, 2006). For this reason, the nitrate/nitrite and arginine/citrulline levels in the NR and NOS pathway, respectively, were determined. It was found that water stress significantly increased NOS activity and accelerated the conversion of arginine to citrulline. However, the arginine content was significantly enhanced in the NH_4^+ -treated roots after the NOS inhibitor application, in relation to the CK roots. These results provide additional evidence that the early NO burst in NH_4^+ -treated roots is mainly mediated by NOS (Fig. 7).

Our study is the first to demonstrate that the early NO burst in NH_4^+ -treated rice roots significantly enhanced plant antioxidant defense by reducing ROS accumulation and enhancing the activities of antioxidant enzymes, thereby increasing plants' acclimation to water stress. The early NO burst which occurs in response to water stress may be triggered by NOS-like enzymes in root. Our results provide new insight into how NO-signaling molecules modulate drought tolerance in NH_4^+ -supplied rice plants. However, the signaling crosstalk between ROS and RNS in response to water stress merits further investigation and may help elucidate the role of the NO-signaling process in enhancing drought tolerance in NH_4^+ -supplied rice.

Figure legends

Fig. 1. Time-dependent endogenous nitric oxide (NO) production and histochemical detection of oxidative damage in the root apices of NH_4^+ - and NO_3^- -supplied rice seedlings under water stress. (a) Detection of NO fluorescence using 4-amino-5-methylamino-2',7'-difluorofluorescein diacetate (DAF-FM DA) staining and a fluorescence microscope. NO generation is indicated by green fluorescence. Bar=300 μm . (b) NO production is expressed as relative fluorescence. To detect the NO production time course, seedling roots exposed to 10% polyethylene glycol(PEG) were collected at 0, 3, 6, 12, 24, and 48 h. (c) and (d) Histochemical detection of the aldehydes derived from lipid peroxidation and Evans blue uptake in root apices of rice seedlings under water stress. Rice seedlings were either untreated or subjected to 3 or 24 h of water stress, respectively. Roots were stained with Schiff's reagent (c) and Evans blue (d), and then immediately photographed under a Leica S6E stereomicroscope (Leica, Solms, Germany). Red/purple indicates the presence of lipid peroxidation detected with Schiff's reagent. Bar=1 mm. Endogenous NO concentrations and histochemical detection of oxidative damage in the root are given. In Fig. 2b, the red dotted oval represents the high endogenous NO production in the NH_4^+ - and NO_3^- -supplied rice, respectively. Values represent means $\pm$ standard error (SE) (n=10). CK indicates control treatment, i.e., plants receiving sufficient water.

Fig. 2. Responses of endogenous nitric oxide (NO) concentrations to water stress (a, b) and NO donor and NO scavenger (c, d) in root apices. (a) Photographs of NO production after sodium nitroprusside (SNP) application. Bar=300 μm . (b) NO production expressed as relative fluorescence. Rice seedlings were either untreated or treated with SNP under water stress. After 3 h and 24 h of treatment, root tips were loaded with 10 μM 4-amino-5-methylamino-2',7'-difluorofluorescein diacetate (DAF-FM DA) and NO fluorescence was imaged after 20 min using a fluorescence microscope. Endogenous NO concentrations in root are displayed. Values represent means $\pm$ standard error (SE) (n=10). Different letters indicate significant differences at $P<0.05$. CK, control treatment, i.e., plants receiving sufficient water.

Fig. 3. Reactive oxygen species (ROS) and peroxynitrite (ONOO^-) accumulation in root apices of rice seedlings treated with NO donor (sodium nitroprusside) and either receiving sufficient water (CK treatment) or subjected to water stress using polyethylene glycol(PEG). After 3 h, O_2^- (a), H_2O_2 (b), and OH^- (c) levels in rice seedlings roots were measured by spectrophotometry. The accumulation of ONOO^- was detected with 10 μM aminophenyl fluorescein. Fluorescence images and relative fluorescence intensity were analyzed as described in Fig. 2 for NO determination.

Fig. 4. Responses of oxidative damage in root apices of rice seedlings to NO donor (sodium nitroprusside) and NO scavenger (2-(4-carboxyphenyl)-4,4,5,5-tetramethylimidazoline-1-oxyl-3-oxide; c-PTIO) in plants either receiving sufficient water (CK treatment) or subjected to water stress using polyethylene glycol (PEG). In the c-PTIO and PEG + c-PTIO treatments, the rice seedlings were pretreated with NO scavenger (c-PTIO) for 3 h followed by sufficient water or water stress. After 3 h, the malondialdehyde (MDA) content was determined. The MDA in rice roots represents lipid peroxidation (a) and carbonyl concentration (b). Values represent means $\pm$ standard error (SE) (n=6). Different letters indicate significant differences at $P < 0.05$ level.

Fig. 5. Effects of a nitrate reductase(NR) inhibitor (tungstate) and a nitric oxide (NO) synthase (NOS) inhibitor (Nx-nitro-L-arginine methyl ester hydrochloride; L-NAME) on NO content and oxidative damage in root apices of rice seedlings. Rice seedlings were pretreated with NR inhibitor (100 μM tungstate) or NOS inhibitor (100 μM L-NAME) for 3 h, and then subject to water treatment. (a) NO fluorescence. Bar = 300 μm . (b) NO production expressed as relative fluorescence. (c, d) malondialdehyde (MDA) content representing lipid peroxidation (c) and carbonyl concentration (d) in rice seedling roots measured after 3 h of water treatment following tungstate or L-NAME pretreatment. Values represent means $\pm$ standard error (SE) (n=6). Different letters indicate significant differences at $P < 0.05$ level. CK, control treatment, i.e.,

plants receiving sufficient water.

Fig. 6. Effects of different treatments on antioxidant enzyme changes in rice seedlings under water stress. Roots were collected to assay catalase (CAT) (a), superoxide dismutase (SOD) (b), ascorbate peroxidase (APX) (c), and peroxidase (POD) (d) after 3 h of treatment with sufficient water (CK treatment) or water stress. For the 2-(4-carboxyphenyl)-4,4,5,5-tetramethylimidazoline-1-oxyl-3-oxide (c-PTIO), polyethylene glycol (PEG) + c-PTIO, and PEG + Nx-nitro-*L*-arginine methyl ester hydrochloride (L-NAME) treatments, the rice seedlings were pretreated with NO scavenger (c-PTIO) or NOS inhibitor (100 μ M L-NAME) for 3 h followed by sufficient water or water stress. Values represent means $\pm$ standard error (SE) (n=6). Different letters indicate significant differences at $P < 0.05$ level.

Fig. 7. Schematic illustration of a proposed model for the different responses of early NO production and its effects on the defense response of rice to water stress. In the roots of NH_4^+ -supplied rice, the nitric oxide synthase (NOS)-mediated early nitric oxide (NO) burst (3h) significantly enhanced plant antioxidant defense by reducing reactive oxygen species (ROS) accumulation and enhancing antioxidant enzyme activity; the relative lower NO production after 24 h of water stress in comparison to NO_3^- -supplied rice, also helped maintaining the redox balance in root cells, thus enhancing their drought tolerance. In the roots of NO_3^- -supplied rice, ROS accumulation and oxidative damage induced by 3h of water stress were significantly higher than that in NH_4^+ -supplied rice. High NO accumulation in the NO_3^- -treated roots likely caused the nitrosative stress at 24 h of water stress. A combined effect of oxidative and nitrification stresses might have led to the weak resistance to water stress in NO_3^- -supplied rice. NR, nitrate reductase. Red arrows represent increase, green arrows represent decrease. Black solid arrows represent defined pathways, dotted arrows represent undefined pathway.

Legends to supplementary figures

Fig. S1. (a), (b), and (c) response of NH_4^+ - and NO_3^- -supplied rice agronomic characteristics and biomass to water stress induced by 10% PEG after 21days of treatment. (d) Effects of water stress on leaf photosynthesis in NH_4^+ - and NO_3^- -supplied rice after 21days of treatment. (e) Effects of water stress on root activity in NH_4^+ - and NO_3^- -supplied rice after 21days of treatment. (f) Effects of water stress on root ^{15}N -labeled uptake rate in NH_4^+ - and NO_3^- -supplied rice after 21days of treatment. Rice leaf photosynthesis, root activity, and ^{15}N uptake rate were determined according to Method S1. Values represent means $\pm$ SE (n=6). Different letters indicate significant differences at $P<0.05$ level. CK, control treatment, i.e., plants receiving sufficient water.

Fig. S2. Effect of exogenous NO donor (SNP) on root oxidative damage under water stress. Rice roots were exposed to mixed N (NH_4^+ + NO_3^-) nutrient solution containing 0 μM , 5 μM , 10 μM , 20 μM , 40 μM , 80 μM , or 100 μM SNP either with or without 10% PEG for 48 h. MDA levels representing lipid peroxidation (a) and carbonyl concentration (b) in rice seedling roots were determined. Values represent means $\pm$ SE (n=6). Different letters indicate significant differences at $P<0.05$ level. CK, control treatment, i.e., plants receiving sufficient water.

Fig. S3. Effect of water stress on NR (a) and NOS (b) in root apices of rice seedlings. Roots were collected for the NR and NOS assays after 3 h and 24 h of water stress, respectively. Values represent means $\pm$ SE (n=6). Different letters indicate significant differences at $P<0.05$ level. CK, control treatment, i.e., plants receiving sufficient water.

Fig. S4. Related compounds in NR-mediated and NOS-mediated NO pathways in root apices of rice seedlings treated with NR inhibitor (tungstate) and NOS inhibitor (L-NAME) under sufficient water or water stress treatment. (a) Levels of nitrate and nitrite in NO_3^- -treated roots. (b) Levels of arginine and citrulline in NO_3^- -treated roots.

(c) Levels of arginine and citrulline in NH_4^+ -treated roots. For the PEG + Tungstate and PEG + L-NAME treatments, the rice seedlings were pretreated with NR inhibitor (100 μM tungstate) or NOS inhibitor (100 μM L-NAME) for 3 h, followed by sufficient water (CK treatment) or water stress treatment. Values represent means $\pm$ SE (n=6). Different letters indicate significant differences at $P<0.05$ level.
