ABSTRACT:

The ventral tegmental area (VTA) is a heterogeneous midbrain structure, containing neurons and astrocytes, that coordinates approach and avoidance behaviors by integrating activity from numerous afferents. Within astrocyte-neuron networks, astrocytes control signals from distinct afferents in a circuit-specific manner, but whether this capacity scales up to drive motivated behavior has been undetermined. Using genetic and optical dissection strategies in vitro and during behavior we report that VTA astrocytes tune glutamatergic signaling selectively on local inhibitory neurons to drive a functional circuit for learned avoidance. In this circuit, VTA astrocytes facilitate excitation of local GABA neurons to increase inhibition of dopamine neurons. The increased inhibition of dopamine neurons elicits real-time and learned avoidance behavior that is sufficient to impede expression of learned preference for reward. Despite the large number of functions performed by astrocytes, loss of one glutamate transporter (GLT-1) from VTA astrocytes selectively blocks these avoidance behaviors and spares preference for reward. Thus, VTA astrocytes selectively regulate excitation of local GABA neurons to drive a distinct learned avoidance circuit that opposes learned approach behavior.

MAIN:

The ability to coordinate approach and avoidance actions in different environments can determine individual survival. Avoidance learning is an adaptive mechanism, but can become maladaptive and lead to the development and persistence of many specific anxiety disorders like post-traumatic stress and social anxiety disorders¹. Dopamine signaling from the ventral tegmental area (VTA) mediates approach and avoidance learning². However, the VTA is a heterogeneous structure containing astrocytes and neurons that receive mixed and distributed signals from various independent afferents conveying information for cues that drive both approach and avoidance^{3,4}. For example, both aversive stimuli and reward expectation increase VTA GABA neuron firing and can inhibit dopamine neurons, leading to avoidance and reduction in approach behaviors⁵⁻⁹. A mechanism capable of separating different signals underlying reward and aversion within the VTA is therefore necessary to appropriately coordinate approach and avoidance, respectively. By selectively affecting activity of different neurons, VTA astrocytes may be positioned to coordinate avoidance and approach behaviors.

Astrocytes express receptors and transporters that are activated by synaptically released neurotransmitters from neuronal afferents¹⁰⁻¹³. The contribution of glutamate transporters to signaling in astrocyte-neuron networks varies considerably among synapses and often changes depending on afferent activity, local ionic environment, and structure of the synapse¹⁴⁻¹⁶. Thus, rather than indiscriminately uptaking glutamate, astrocytes are diverse regulators of neuronal processing that can delineate synapse-specific control to circuits in response to neuronal afferent activity¹⁷⁻²². Astrocytes control glutamate availability at synapses of actively firing afferents primarily by the glutamate transporter, GLT-1 (EAAT2, SLC1A2), making them ideally suited to dynamically control glutamate at specific synapses throughout a wide concentration range²³⁻²⁵.

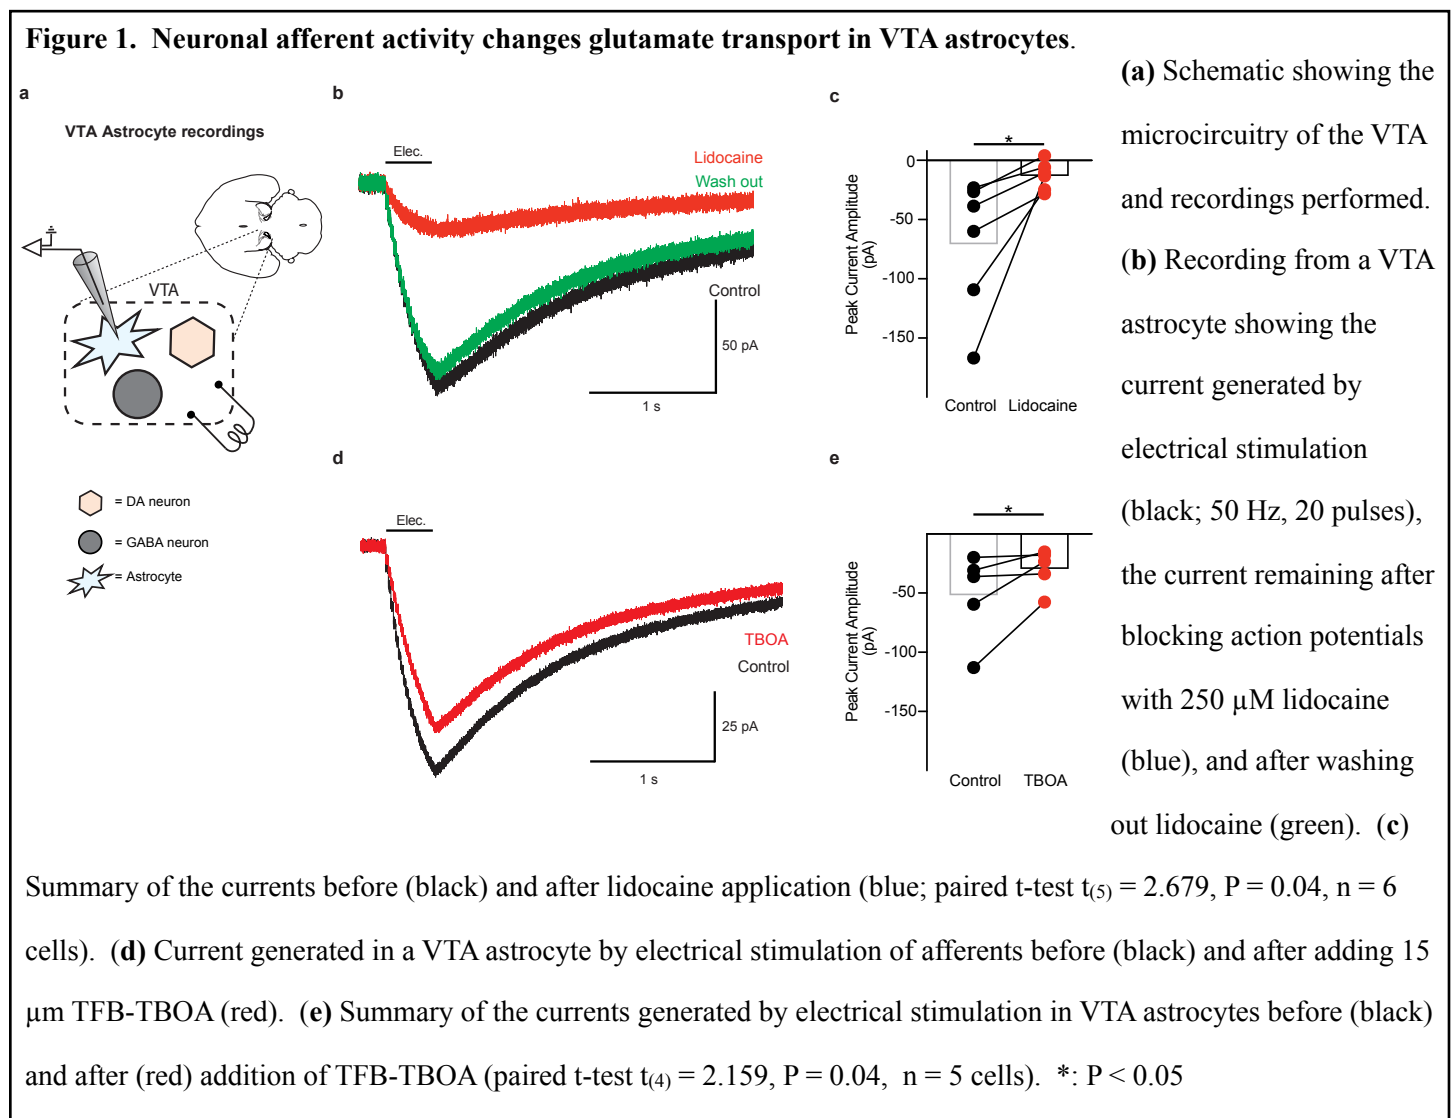

In the present study, we examined the role of astrocytes in the VTA on avoidance behavior. We found that VTA astrocytes 1) selectively facilitate glutamatergic excitation of local GABA neurons through a mechanism that requires astrocytic GLT-1; 2) generate a subsequent GABA neuron-dependent inhibition of dopamine

neurons; and 3) consequently drive learned avoidance that is sufficient to block conditioned place preference for cocaine. Conditional mutants lacking GLT-1 in VTA astrocytes fail to express avoidance behaviors, but maintain preference for reward. These experiments establish that VTA astrocytes selectively leverage glutamatergic excitation of local GABA neurons to dynamically define a privileged channel underlying behaviors associated with aversion, but not reward.

RESULTS:

Astrocytes modulate excitation of VTA GABA neurons and inhibition of dopamine neurons

To investigate the mechanism by which astrocytes regulate the circuitry of the VTA, and potentially elicit avoidance behavior, we obtained ex vivo recordings of VTA astrocytes (Fig. 1a). We first determined that neuronal afferent stimulation elicits action potential-dependent currents in VTA astrocytes (Fig. 1). Electrical

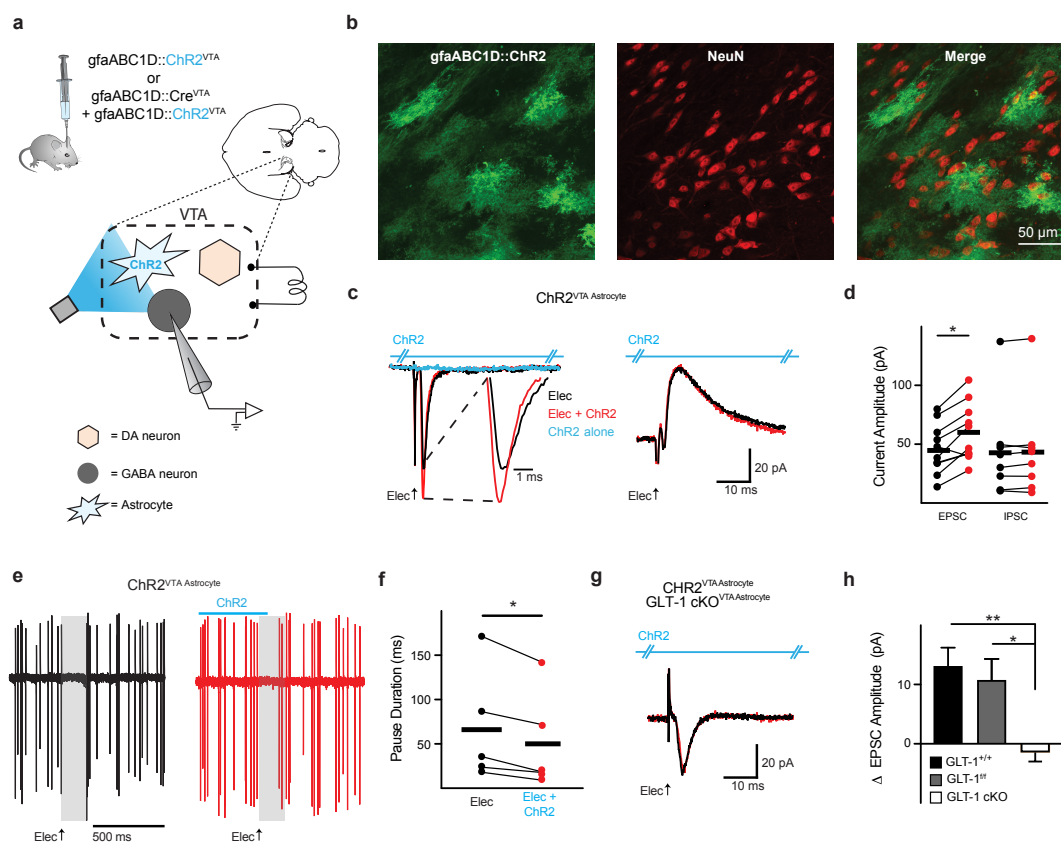

stimulation of the VTA during whole-cell voltage-clamp recordings of astrocytes resulted in a lidocaine-sensitive inward current (Fig. 1 b-c). A significant portion of the inward current was sensitive to the glutamate transporter blocker, TFB-TBOA (15 μ M), indicating that neuronal afferent input modulates glutamate transporter activity on VTA astrocytes (Fig. 1 d-e).

Astrocytes display a phasic increase in cytoplasmic Na^+ and H^+ , and a decrease in K^+ concentrations, among other ions, in response to afferent activity²⁶⁻²⁹. The ensuing fast changes in electrochemical gradient generate biophysical fluctuations in GLT-1 function^{29,30}. To mimic the activity of neuronal inputs on astrocytic glutamate transport, we used an optogenetic strategy to selectively activate VTA astrocytes. Photoactivation of the light-sensitive opsin, channelrhodopsin (ChR2), also results in a phasic increase in cytoplasmic Na^+ and H^+ , and decrease in K^+ concentrations^{31,32}. Therefore, owing to its cation permeability and time resolution³¹, ChR2 presents as an ideal tool to transiently influence astrocytic GLT-1 dynamics with a temporal fidelity capable of mimicking native astrocyte gradient dynamics^{29,33}. ChR2 was expressed selectively in VTA astrocytes by injecting adeno-associated virus (AAV) to drive expression of ChR2 under the gfaABC1D promoter (gfaABC1D::ChR2^{VTA}; Fig. 2a-b)³⁴. We then confirmed that both neuronal afferent stimulation and optogenetic photoactivation of astrocytes similarly affect glutamate transporter-mediated currents in VTA astrocytes (Fig. S1).

Since behavioral avoidance can be induced directly by excitation of VTA GABA neurons^{6,7}, we investigated whether local GABA neurons are subject to modulation by VTA astrocytes. We found that during voltage-clamp recordings of VTA GABA neurons (Fig. S2), electrically-stimulated excitatory postsynaptic currents (EPSCs) increased in peak amplitude when the electrical stimulation was paired with ChR2 photoactivation on VTA astrocytes (GLT-1^{ff}, Elec = 22.0 ± 3.7 pA, Elec + ChR2 = 32.4 ± 6.6 ; paired t-test $t_{(5)} = 3.147$, $P = 0.025$, $n = 6$ cells) with no effect on inhibitory postsynaptic currents (IPSCs) (GLT-1^{ff}, Elec = 44.8 ± 18.1 pA, Elec + ChR2 = 40.4 ± 22.1 ; paired t-test $t_{(4)} = 0.8756$, $P = 0.43$, $n = 5$ cells; Fig. 2c-d). When the same cells were recorded in cell-attached mode, electrical stimulation of all afferents in the brain slice (no blockers were

Figure 2. Astrocytic GLT-1 increases excitation of VTA GABA neurons.

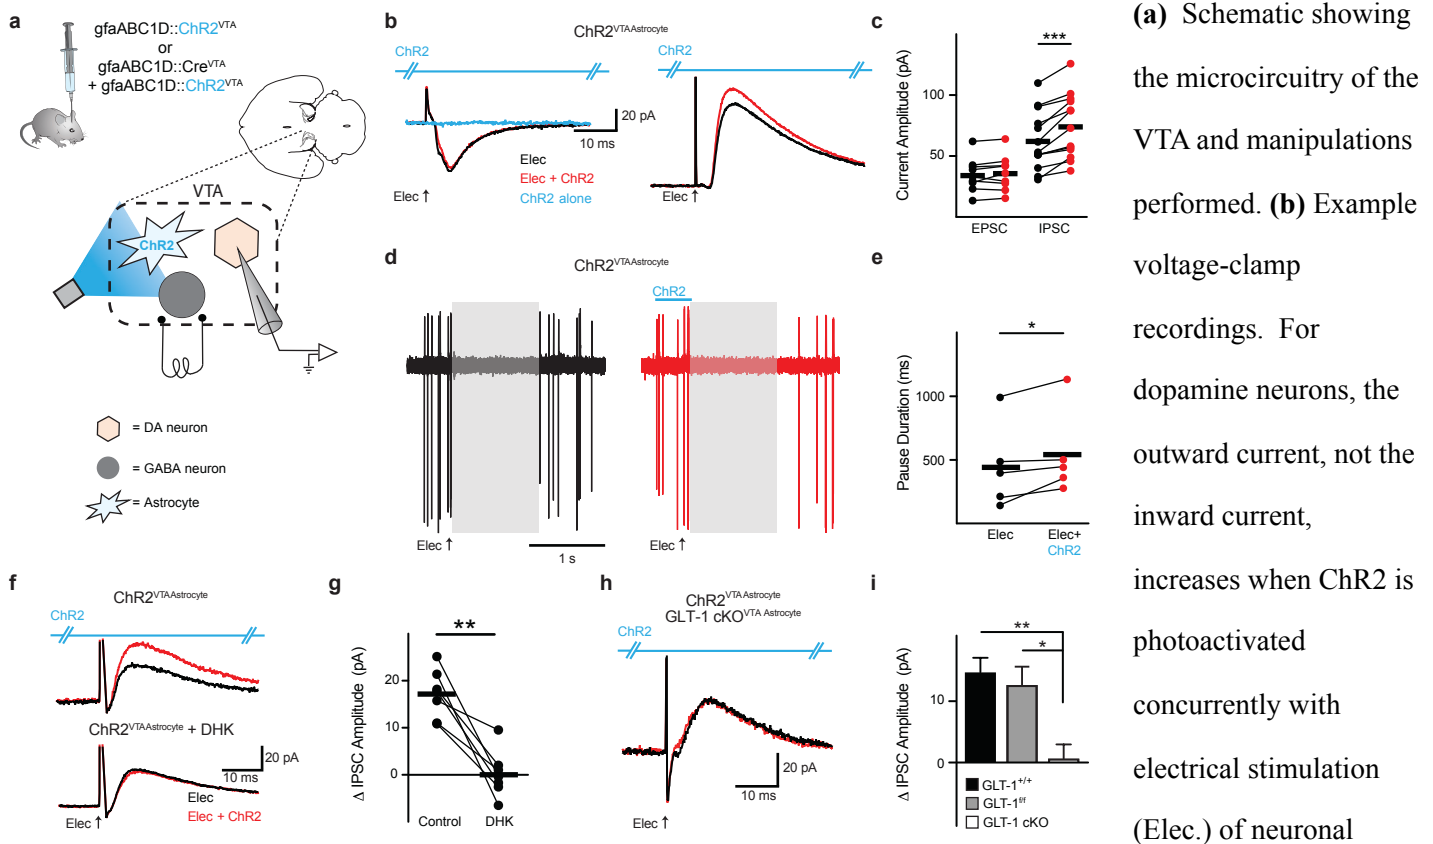

present) elicited a net pause in firing. When the electrical stimulation was paired with photoactivation of astrocytes, the pause duration decreased, which is consistent with an increase in EPSC amplitude observed in voltage-clamp mode (Fig. 2e-f).

We next sought to determine whether VTA astrocytes increase excitation of local GABA neurons in a glutamate transporter-dependent manner. We drove a conditional knock out (cKO) by injecting an adeno-associated virus (AAV) into the VTA of GLT-1 floxed mice (GLT-1^{f/f})³⁵ to restrict recombination and loss of GLT-1 to VTA astrocytes (GLT-1^{f/f}, AAV(gfaABC1D-Cre) → VTA; Fig. 2a, S3). The increase in EPSC amplitude elicited by astrocyte photoactivation was absent when GLT-1 was conditionally knocked out from VTA astrocytes (GLT-1 cKO^{VTA Astrocyte}; Elec = 28.18 ± 4.5 pA, Elec + ChR2 = 28.6 ± 3.8; paired t-test $t_{(7)} = 0.3152$, P = 0.76, n = 8; Fig. 2g-h), indicating that astrocyte activation increases EPSC amplitude via GLT-1 in VTA GABA neurons.

Contrary to what we observed from GABA neurons, when we recorded in voltage-clamp from VTA dopamine neurons (Fig. S4), the IPSC peak amplitude increased, but the EPSC was unaffected, when electrical stimulation was paired with VTA astrocyte photoactivation (GLT-1^{f/f} IPSC, Elec = 44.7 ± 10.6 pA, Elec + ChR2 = 56.9 ± 11.4; paired t-test $t_{(6)} = 4.243$, P = 0.0054, n = 7 cells, GLT-1^{f/f} EPSC: Elec = 40.4 ± 11.3 pA, Elec + ChR2 = 42.8 ± 12.4; paired t-test $t_{(6)} = 1.199$, P = 0.27, n = 7 cells; Fig. 3a-c). When the same dopamine cells were recorded in cell-attached mode, electrical stimulation of all afferents in the brain slice also elicited a net pause in firing. However, when the electrical stimulation was paired with photoactivation of astrocytes, the pause duration increased (Fig. 3d-e), which is consistent with the increase in IPSC amplitude observed in voltage-clamp mode. The increase in IPSC amplitude was blocked when the glutamate transporter blocker, DHK (300 μM), was added during the same recording (paired t-test $t_{(6)} = 5.675$, P = 0.0013, n = 7 cells; Fig. 3f-g). Also, when GLT-1 was conditionally knocked out from VTA astrocytes, the IPSC amplitude on DA neurons was unaffected by astrocyte activation paired with electrical stimulation (GLT-1 cKO^{VTA Astrocyte}; Elec = 51.7 ± 9.5 pA, Elec + ChR2 = 52.4 ± 10.2; paired t-test $t_{(7)} = 0.2926$, P = 0.77, n = 8 cells; Fig. 3h-i). Importantly, the

effect of GLT-1 manipulation was dependent on active synaptic input since in vitro photoactivation of VTA astrocytes without electrical stimulation of neuronal afferents had no effect on either VTA dopamine or GABA

Figure 3. Astrocytic GLT-1 increases inhibition of VTA dopamine neurons.

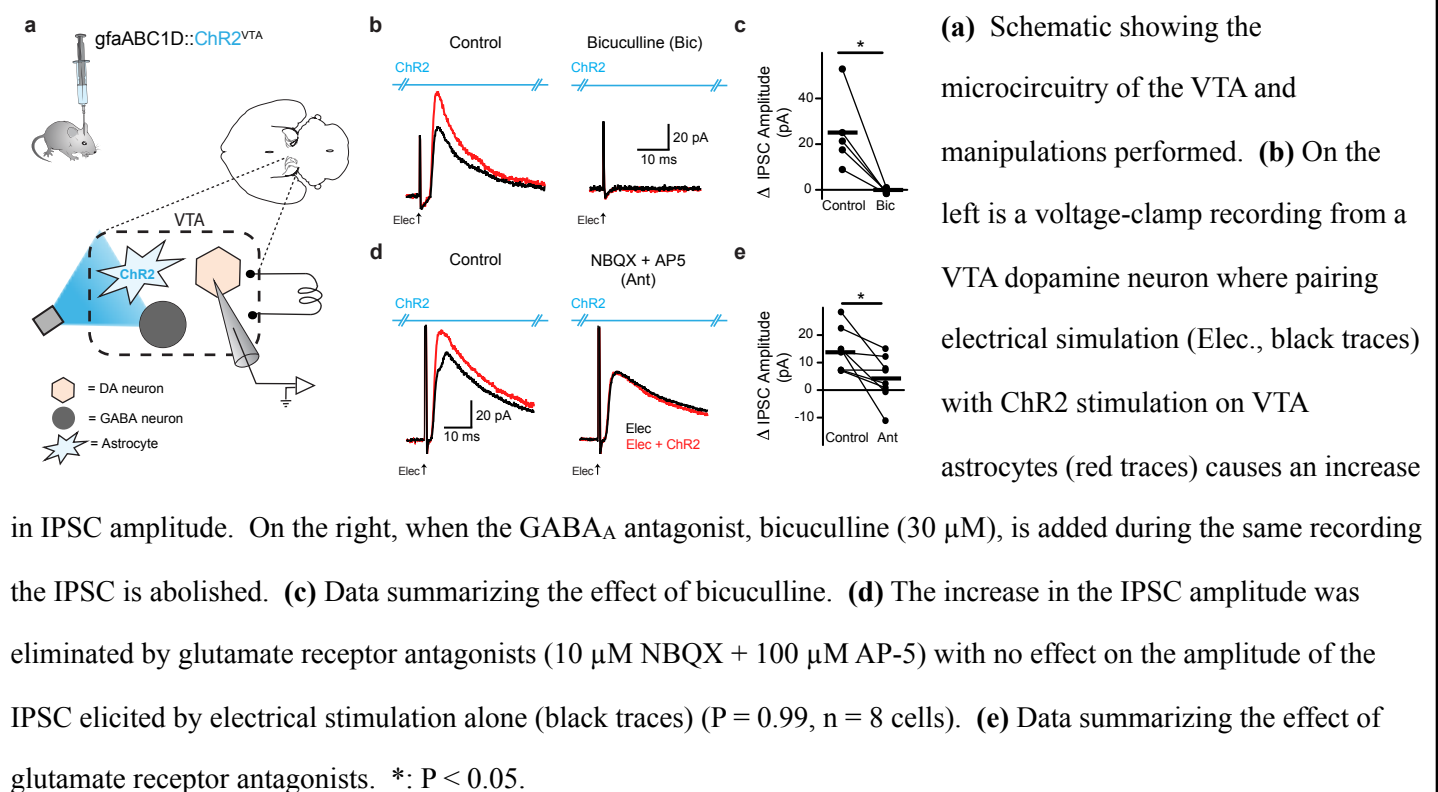

afferents (red traces). Photoactivation of ChR2 alone elicits no response (blue trace). **(c)** Summarized data from VTA dopamine neurons where ChR2 stimulation on VTA astrocytes increases peak IPSC amplitude (paired t-test $t_{(12)} = 5.894$, $P = 0.0001$, $n = 13$ cells) without altering EPSCs (paired t-test $t_{(9)} = 1.129$, $P = 0.28$, $n = 10$ cells). **(d)** Cell-attached recordings and **(e)** summarized data from VTA dopamine neurons demonstrating an increase in pause duration (paired t-test $t_{(4)} = 2.815$, $P = 0.04$, $n = 5$ cells) when ChR2 stimulation on VTA astrocytes is delivered concurrently with electrical stimulation of neuronal afferents (red traces; both grey areas are the pause duration following electrical stimulation alone). **(f, g)** The increase in IPSC amplitude (red trace, top) is abolished by pharmacologically blocking GLT-1 with 300 μ M DHK (bottom traces). **(h)** When GLT-1 is conditionally knocked out from VTA astrocytes there is no change in IPSC caused by activating ChR2 on astrocytes. **(i)** Summarized data comparing the change in IPSC amplitude between GLT-1^{+/+}, GLT-1^{f/f}, and GLT-1 cKO^{VTA Astrocyte} mice (One-way ANOVA, $F_{(2,27)} = 7.732$, $P = 0.0022$; post-hoc Tukey's test GLT-1^{+/+} vs GLT-1^{f/f} $P > 0.05$, GLT-1^{+/+} vs GLT-1 cKO^{VTA Astrocyte} $P < 0.05$, GLT-1^{f/f} vs GLT-1 cKO^{VTA Astrocyte} $P < 0.05$, $n = 11$, $n = 6$, $n = 8$ cells respectively). **: $P < 0.01$, *: $P < 0.05$; Error bars indicate \pm SEM.

neurons (Fig. 2c, 3b, S5). Thus, astrocytes use a GLT-1-dependent mechanism to increase both excitation in GABA neurons and inhibition in dopamine neurons, but only during ongoing activity of neuronal afferents.

VTA GABA neurons mediate the astrocyte-dependent increase in inhibition of dopamine neurons

Given the surprising result of a glutamate transporter mediating the increase of an outward current in dopamine neurons, we next determined whether the outward current was indeed an IPSC mediated by an inhibitory input. We tested the sensitivity of the outward current to the GABA_A receptor antagonist, bicuculline (30 μ M). Both the electrically-induced IPSC, and the peak amplitude increase elicited by pairing electrical stimulation with photoactivation of astrocytes, were abolished by addition of bicuculline, indicating that all outward currents were mediated by GABA_A receptor activation (paired t-test $t_{(4)} = 3.682$, $P = 0.0015$, $n = 5$ cells; Fig. 4a-c). However, only the increase in IPSC amplitude, not the electrically-elicited outward current per se, was sensitive to glutamate receptor antagonism (10 NBQX + 100 AP5, paired t-test $t_{(7)} = 3.101$, $P = 0.0173$, $n = 8$ cells, 4d-e). Since 1) ChR2 activation increased the EPSC amplitude on VTA GABA neurons, and 2) the

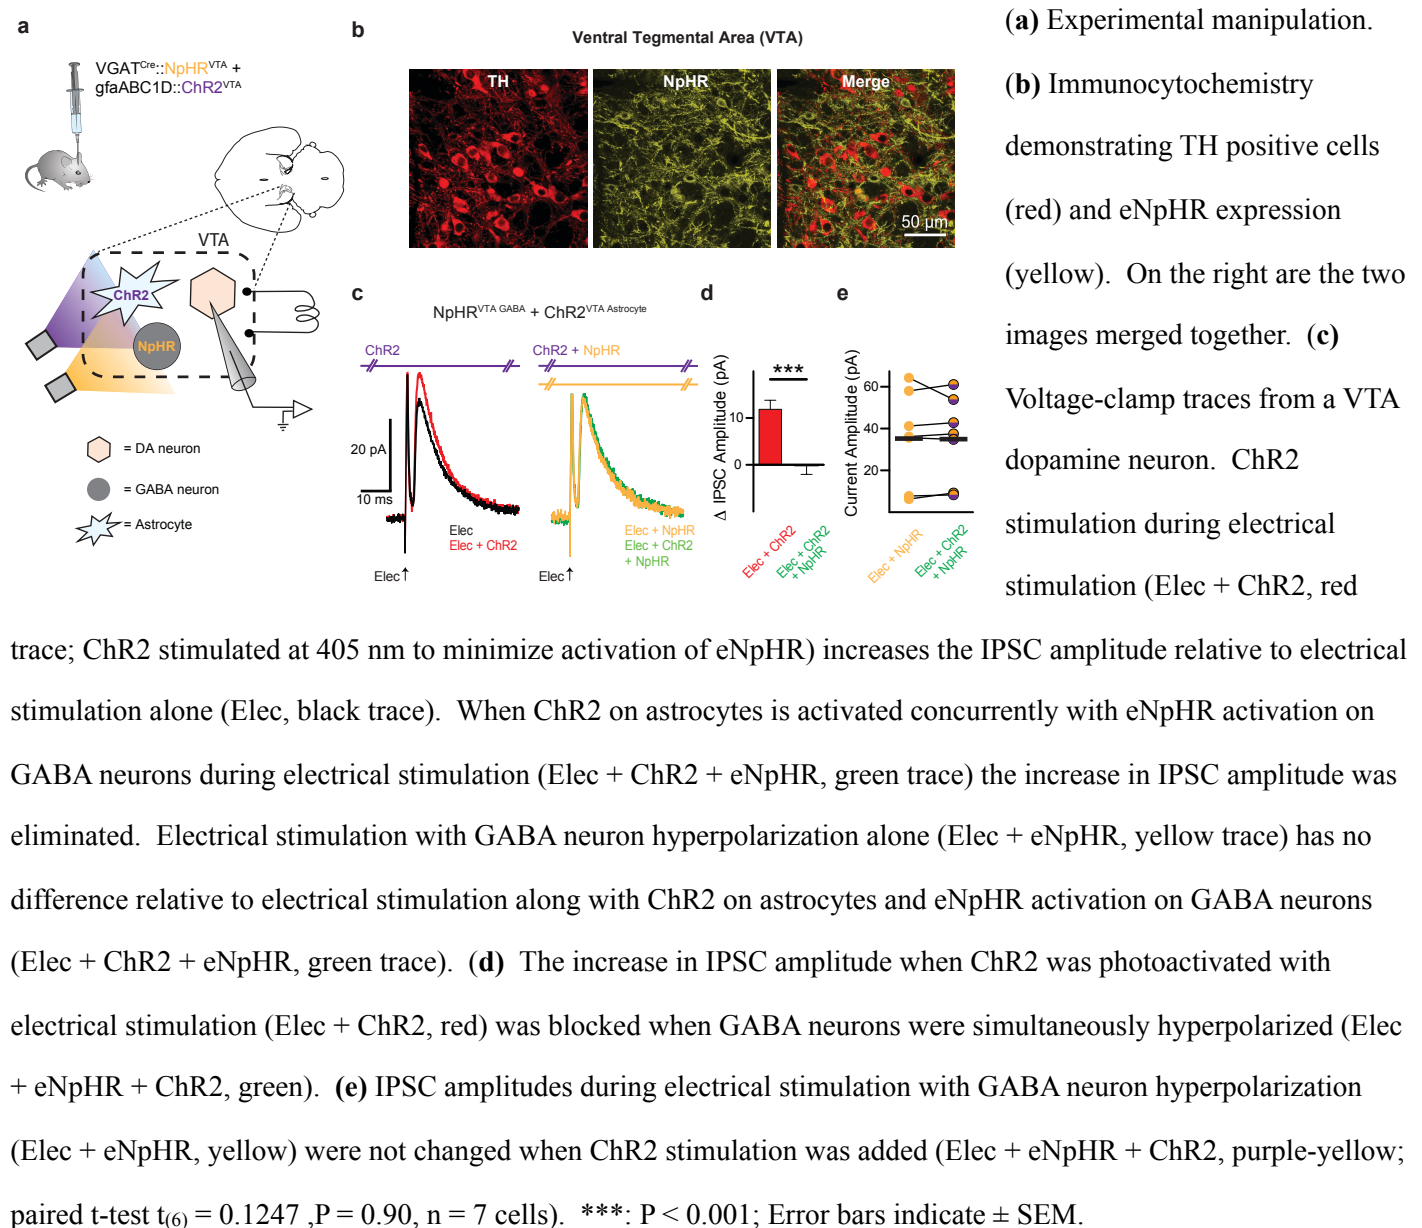

Figure 4. Increase in dopamine neuron inhibition is dependent on glutamate receptor activation.

increased IPSC on dopamine neurons was dependent on glutamate receptor activation, dopamine neurons may be inhibited via a circuit mechanism involving depolarization of GABA neurons.

To directly test whether local GABA neurons mediated the effects of astrocyte activation on dopamine neuron inhibition, we optogenetically hyperpolarized VTA GABA neurons (VGAT^{Cre}::eNpHR^{VTA}) during photoactivation of ChR2 on VTA astrocytes (gfaABC1D::ChR2^{VTA}; Fig. 5a-b; S6-7). Optogenetic hyperpolarization of VTA GABA neurons prevented the increase in IPSC amplitude, recorded from neighboring dopamine neurons, that resulted from combining electrical stimulation with optogenetic activation of VTA

Fig. 5. Astrocyte-dependent increase in dopamine neuron inhibition is mediated by VTA GABA neurons.

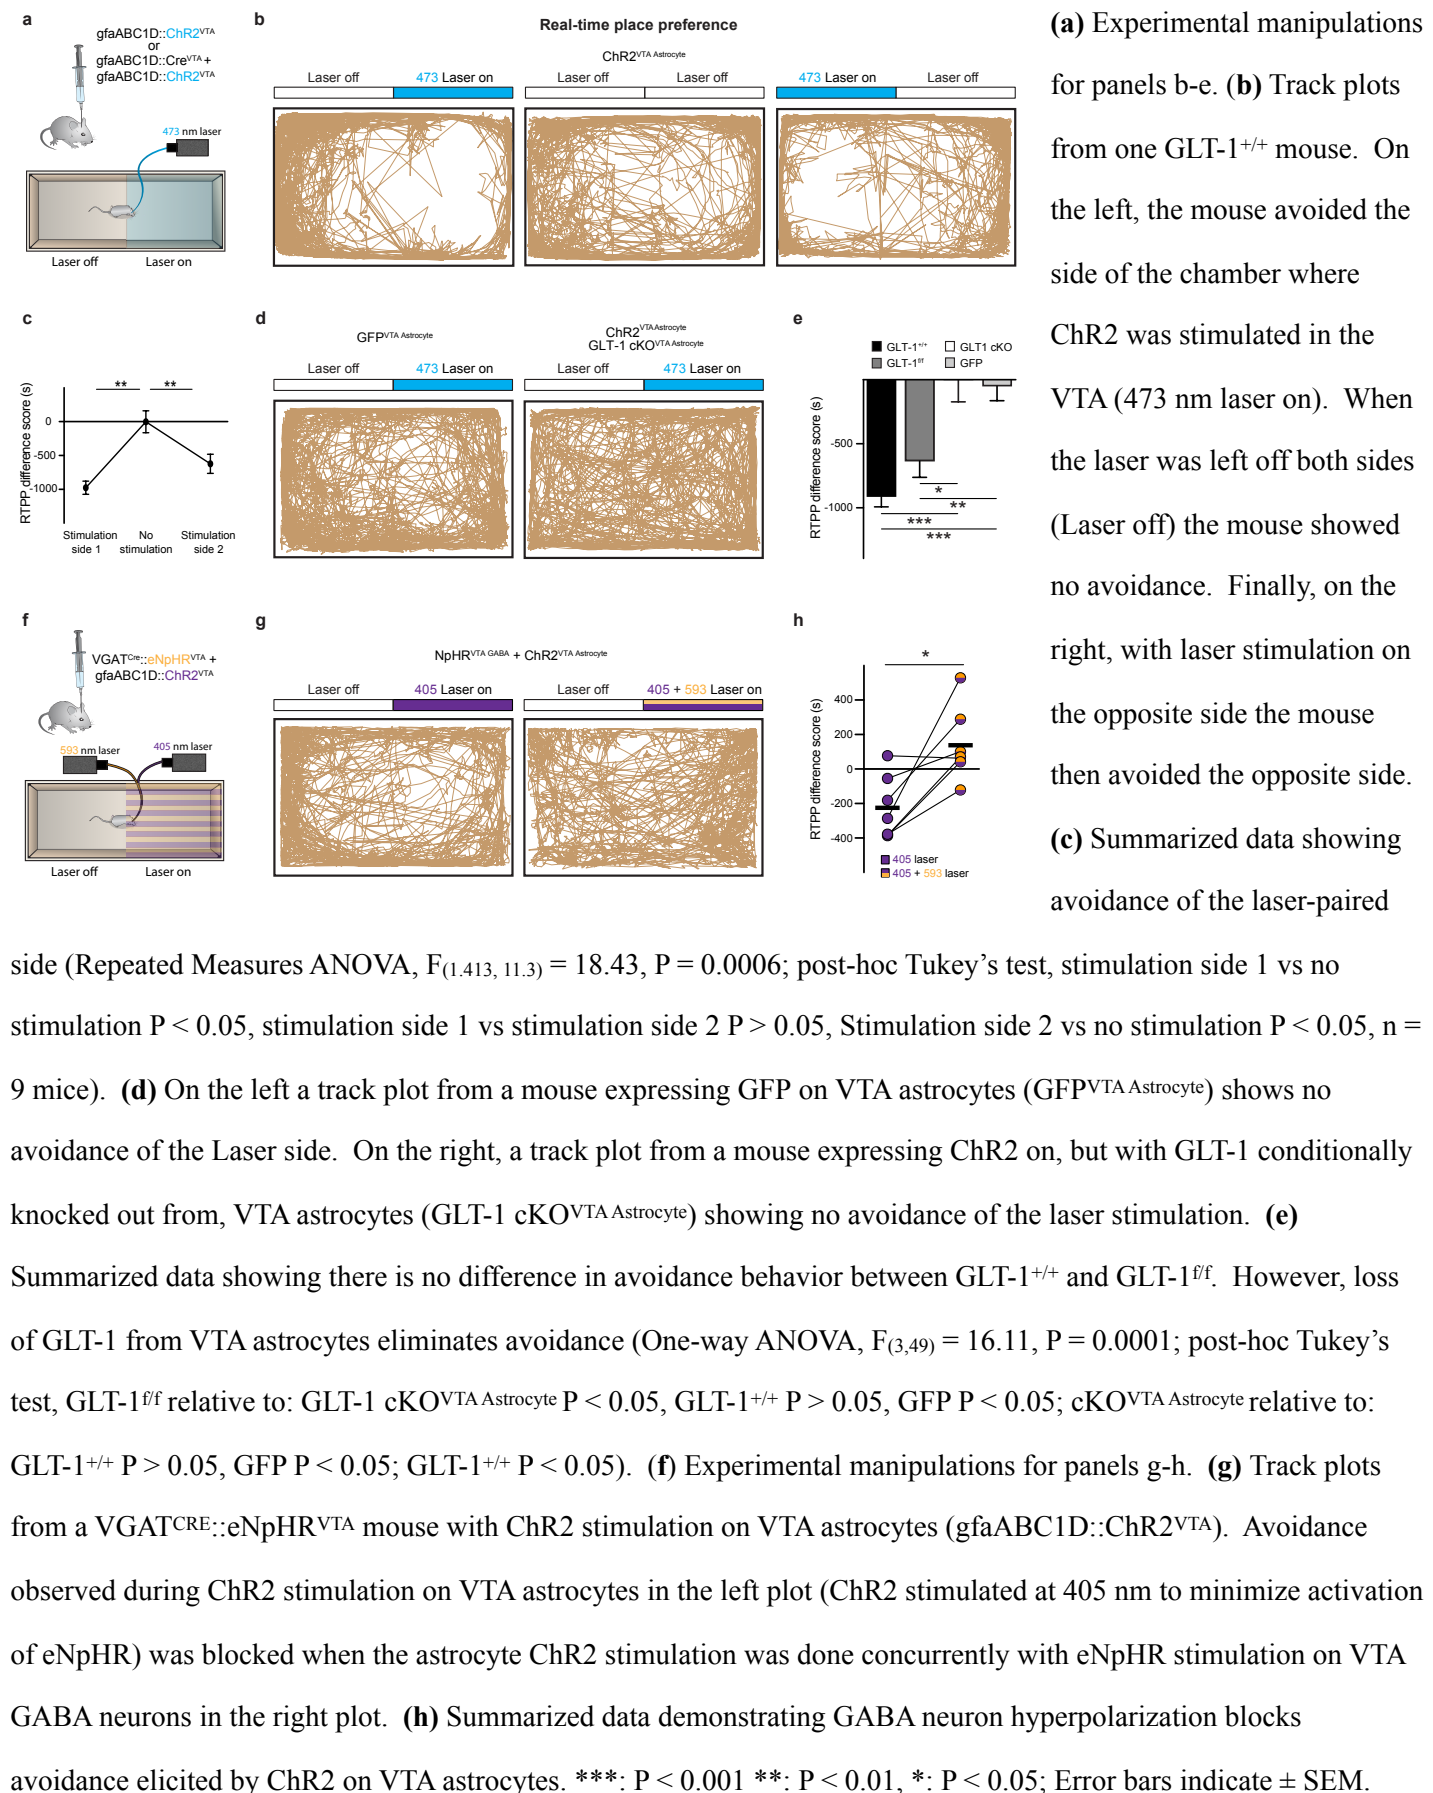

astrocytes during the same recordings (Fig. 5c-e; unpaired t-test $t_{(18)} = 3.961$, $P = 0.0009$, electrical + ChR2: $n = 7$ cells, electrical + ChR2 + NpHR: $n = 13$ cells).

VTA astrocytes drive real-time avoidance mediated by local GABA neurons.

Previous studies demonstrate that direct optogenetic depolarization of VTA GABA neurons inhibits the activity of neighboring dopamine neurons and elicits avoidance behavior^{6,7}. Our recordings demonstrate that VTA astrocytes can increase the response of GABA neurons to active excitatory afferent input, leading to increased inhibition of dopamine neurons. We therefore aimed to determine whether ChR2 activation of astrocytes would directly drive avoidance behavior. Extending our same optogenetic strategy to behavioral assays, we found that photoactivation of VTA astrocytes induced real-time avoidance in control mice in a real-time place preference (RTPP) assay (GLT-1^{+/+}, paired t-test $t_{(17)} = 11.56$, $P = 0.0001$, $n = 18$ mice; Fig. 6a-c; S8; Supplementary Video 1). The effect of astrocyte activation was reversible since mice could be manipulated to avoid either side of the chamber by changing which side was paired with laser stimulation (Fig. 6b-c). The avoidance behavior was also dependent on astrocytic GLT-1 since conditional knockout restricted to VTA astrocytes (GLT-1 cKO^{VTA Astrocyte}, gfaABC1D::ChR2^{VTA}) eliminated the real-time avoidance elicited by photoactivating VTA astrocytes (paired t-test $t_{(10)} = 0.1399$, $P = 0.98$, $n = 11$ mice; Fig. 6d-e).

We then confirmed that GABA neuron depolarization is necessary for eliciting real-time place avoidance by optogenetically hyperpolarizing VTA GABA neurons concurrently with ChR2 activation of VTA astrocytes. Similar to the increase in IPSC amplitude in dopamine neurons, real-time avoidance elicited by photoactivation of VTA astrocytes from VGAT^{Cre}::NpHR^{VTA} mice was blocked by concurrently hyperpolarizing local GABA neurons (paired t-test $t_{(6)} = 3.642$, eNpHR + ChR2; $P = 0.01$, $n = 7$ mice; Fig. 6f-h). Therefore, astrocyte activation reliably induced real-time avoidance behavior through astrocytic GLT-1-dependent and GABA neuron depolarization-dependent mechanisms that are consistent with the circuit pathway established in our ex vivo experiments.

Figure 6. Real-time avoidance is dependent on VTA astrocytes and mediated by local GABA neurons.

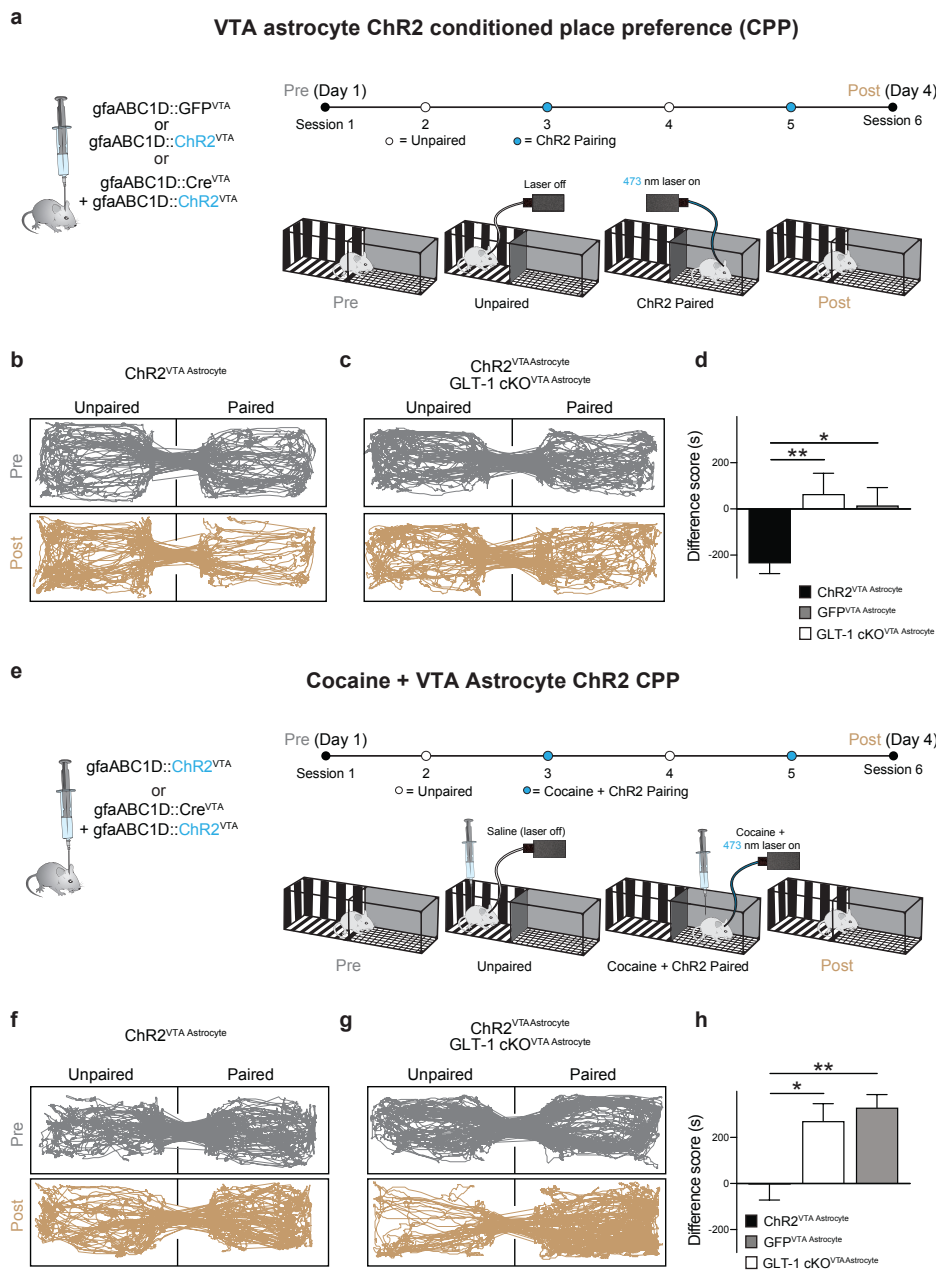

Learned avoidance, but not approach, is dependent on VTA astrocytes.

Because of the VTA's well known involvement in cue-outcome associative learning, we next sought to determine if astrocyte manipulation-evoked avoidance was sufficient to serve as a motivationally relevant signal in an associative learning context. The place conditioning paradigm is particularly well-suited for examining approach or avoidance since it makes use of the fact that mice will readily learn to approach or avoid distinct environments previously paired with either rewarding or aversive events, respectively³⁶. We implemented a conditioned place avoidance (CPA) paradigm using photoactivation of VTA astrocytes as a conditioning stimulus paired to a contextual cue (chamber) during conditioning sessions. Astrocyte activation was sufficient to elicit learned avoidance in the CPA assay (*gfaABC1D::ChR2^{VTA}*; *GLT-1^{f/f}*; paired t-test $t_{(9)} = 3.604$, $P = 0.0057$, $n = 10$ mice; Fig. 7a-d; S8), while *GLT-1* cKO restricted to VTA astrocytes eliminated expression of avoidance learning during the assay (*GLT-1* cKO^{VTA Astrocyte}, *gfaABC1D::ChR2^{VTA}*; paired t-test $t_{(11)} = 0.7296$, $P = 0.48$, $n = 12$; Fig. 7c-d). Thus, VTA astrocytes mediate associative learning of aversive cues through a mechanism that requires expression of astrocyte *GLT-1*.

When a cue predicts both reward and aversion, dopamine neurons' activity responses reflect the integrated value of both outcomes⁹. As a step in establishing astrocytes as functional elements within the VTA approach-avoidance circuit, we sought to disambiguate whether *GLT-1* on astrocytes is positioned within a functional pathway specific to avoidance, or a common pathway that mediates expression of both avoidance and preference. If astrocytes mediate a common pathway, absence of astrocyte *GLT-1* would be expected to abolish expression of both approach and avoidance. To dissect pathway specificity or generality, we used a conditioned place preference (CPP) paradigm to pair a contextual cue with a conditioning stimulus that contained both a strong reward (cocaine, 15 mg/kg) and aversion (photoactivation of VTA astrocytes). Consistent with prior work³⁷, cocaine alone drove robust approach in the CPP assay (*GLT-1^{+/+}* GFP; paired t-test $t_{(8)} = 3.735$, $n = 9$; $P = 0.0057$). However, when cocaine was paired with ChR2 activation on VTA astrocytes during the conditioning sessions, both the preference for cocaine and the avoidance of ChR2 photoactivation were abolished

(gfaABC1D::Chr2^{VTA}: paired t-test $t_{(7)} = 0.7588$, $P = 0.47$, $n = 8$, Fig. 7e-f, S8). Since expression of CPA was mediated by GLT-1 on VTA astrocytes we next sought to determine whether cocaine CPP was also dependent

Figure 7. VTA Astrocytes mediate learned avoidance and prevent learned preference for reward.

(a) Experimental design and manipulations for panels b-d. (b) Track plots showing ChR2 photoactivation on VTA astrocytes elicits learned avoidance in a GLT-1^{+/+} mouse (gfaABC1D::Chr2^{VTA}). (c) The learned avoidance is absent in a mouse where GLT-1 was removed from VTA astrocytes (gfaABC1D::Chr2^{VTA}, GLT-1 cKO^{VTA} Astrocyte). (d) Comparing the difference scores in mice expressing either ChR2 (GLT-1^{+/+} and GLT-1^{f/f}, GLT-1 cKO^{VTA} Astrocyte) or GFP (gfaABC1D::Chr2^{GFP}) in VTA astrocytes. (e) Experimental design and manipulations for panels f-h. (f) Track plots showing astrocyte activation paired with cocaine

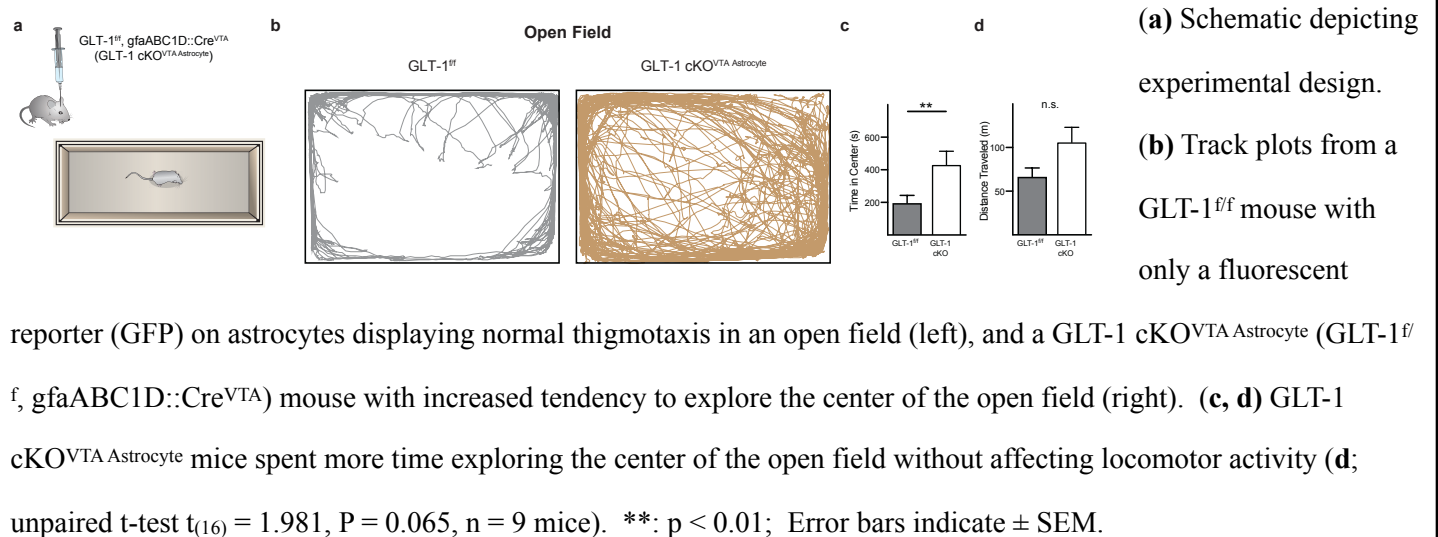

administration does not elicit either learned avoidance or preference in a GLT-1^{f/f} mouse (gfaABC1D::Chr2^{VTA}). (g) However, when GLT-1 is removed from VTA astrocytes (gfaABC1D::Chr2^{VTA}, GLT-1 cKO^{VTA} Astrocyte) a mouse displays robust learned preference for VTA astrocyte ChR2 photoactivation paired with cocaine administration. (h) Comparing the difference scores in mice expressing either ChR2 (GLT-1^{+/+} and GLT-1^{f/f}, GLT-1 cKO^{VTA} Astrocyte) or GFP (gfaABC1D::Chr2^{GFP}) in VTA astrocytes. **: $P < 0.01$, *: $P < 0.05$; Error bars indicate \pm SEM.

on VTA astrocyte GLT-1 expression. Indeed, preference for cocaine remained when cocaine was paired with photoactivation of VTA astrocytes during conditioning in GLT-1 cKO^{VTA Astrocyte} mice (One-way ANOVA, $F_{(2,33)} = 8.295$, $P = 0.0012$; post-hoc Tukey's test GFP vs Chr2 $P > 0.05$, GFP vs GLT-1 cKO^{VTA Astrocyte} $P < 0.05$, Chr2 vs cKO^{VTA Astrocyte} $P > 0.05$; Chr2: $n = 14$, GFP: $n = 10$, GLT-1 cKO^{VTA Astrocyte}: $n = 7$, Fig. 7g-h, S8). Thus, although CPA requires GLT-1 expression in VTA astrocytes and can block expression of learned approach, CPP for cocaine is independent of astrocytic GLT-1 in the VTA.

Astrocytic GLT-1 in the VTA is necessary for endogenous approach-avoidance behavior.

To determine the impact of VTA astrocytic GLT-1 function on endogenous behavior we tested whether selective deletion of GLT-1 in VTA astrocytes is sufficient to skew an animal's natural behavior in an open field test as an ethological assay that indexes approach-avoidance conflict. Mice with GLT-1 cKO restricted to VTA astrocytes (GLT-1 cKO^{VTA Astrocyte}) displayed a decreased tendency to remain in the peripheral zone near the walls of the chamber, and increased tendency to explore the center of the open field, relative to littermate controls (unpaired t-test $t_{(16)} = 2.449$, $P = 0.026$, $n = 9$ mice, Fig. 8a-d). Disrupted approach-avoidance behavior in GLT-1 cKO^{VTA Astrocyte} mice indicates that VTA astrocytes are an integral component of a circuit within the VTA capable of coordinating approach and avoidance behaviors.

Figure 8. GLT-1 removal from VTA astrocytes disrupts endogenous avoidance behavior.

DISCUSSION:

Astrocytes control signaling for avoidance

Our experiments identify, through a series of genetic and optogenetic strategies in slice and in vivo, a specialized VTA microcircuit that is regulated by astrocytes to drive avoidance behavior. We observed that local astrocytes within the VTA circuit modulate glutamate availability via GLT-1 to dynamically regulate active GABAergic inhibition of dopamine neurons. As a result, VTA astrocytes induced robust, time-locked behavioral avoidance de novo. Rapid manipulation of astrocyte glutamate transport in the VTA served as a powerful stimulus that, when paired with cocaine, was sufficient to impede behavioral expression of cocaine CPP. Thus, despite cocaine's many systemic effects, local astrocyte manipulation within the VTA was sufficient to override expression of preference for a highly salient cocaine-associated cue. These experiments suggest that midbrain astrocytes have the capacity to drive behavior, and not merely modulate the gain or polarity of an ongoing behavior. They underscore a computational role for astrocytes in the VTA network, and provide the first evidence that VTA astrocytes can selectively and reliably determine complex motivated behavior.

Separable circuits for avoidance and approach in the VTA

The complexity of afferents arriving at the VTA points to its importance as a nexus where signals related to sensory experience, valence, and behavioral state intersect with associative processes to cue motivated behavior. For example, separate projections from the bed nucleus of the stria terminalis (BNST) to the VTA mediate both aversive and rewarding signals that promote and attenuate anxiety phenotypes, respectively³⁸. But, the BNST provides equivalent projections to both GABA and dopamine neurons within the VTA³⁹. Afferents from the pedunculopontine nucleus to both VTA GABA and dopamine neurons mediate approach behaviors like conditioned place preference for reward^{40,41}. The VTA is therefore capable of parsing avoidance signals from different afferents to drive avoidance behavior and appropriately coordinate approach and avoidance. But a distinct circuit for avoidance capable of sufficiently opposing approach had not been described.

Inhibition exerts a powerful regulatory influence on dopamine neurons⁴², and prior studies establish that direct depolarization of VTA GABA neurons elicits real-time avoidance but fails to disrupt conditioned responses to reward-predictive cues^{6,7}. Our experiments reliably reproduce these results solely through optogenetic activation of VTA astrocytes. Furthermore, they illustrate that a single astrocytic mechanism can facilitate dopamine neuron inhibition, induces both active and learned avoidance, and interferes with expression of cocaine CPP. All rely on GLT-1 expression at VTA astrocytes; when VTA astrocytes lack functional GLT-1, laser-cued conditioning fails to produce learned avoidance, and also fails to block expression of cocaine CPP (Fig. 7g-h). The selective influence of astrocyte mechanisms on avoidance but not approach in the dopaminergic VTA circuit reinforces the view that the microcircuits mediating avoidance and approach are functionally separate within the VTA, but converge at the level of inputs to dopamine neurons⁹.

Our results demonstrate that VTA astrocytes can exert opposing effects on GABA and dopamine neurons through serial excitation of GABA neurons and subsequent inhibition of dopamine neurons. The unexpected lack of direct astrocyte-mediated glutamatergic effects at dopamine neurons concurrent with those observed at GABA neurons highlight the separate circuits for avoidance and approach, and may reflect a partitioning mechanism akin to the basal ganglia wherein distinct subpopulations of astrocytes are functionally linked to either D1-type or D2-type receptor-expressing populations of spiny projection neurons¹⁹. One possibility is that astrocytic glutamate transport is differentially recruited by GABA and dopamine neurons in the VTA. Astrocyte populations that express distinct complements of transporters and receptors have been reported in hippocampus^{18,43}, and may similarly tile the VTA to partition neuron types and their synapses. Additionally, GLT-1 is expressed in both astrocytes and neurons⁴⁴. Conditional genetic deletion of GLT-1 from neurons blunts the effects of amphetamine, and, in direct contrast to the astrocyte GLT-1 knockout (Fig. 8), has no effect on open field behavior⁴⁵. Characterizing the molecular diversity, morphology and distribution of astrocytes within the VTA will be required to fully mine the dimensions of their computational capacity⁴⁶.

Optogenetic manipulation of astrocytes

Astrocytes discriminate the activity of discrete synapses originating from different afferents^{17,22}. Recent work points to the unique molecular and physiological profiles of ventral midbrain astrocytes relative to their telencephalic counterparts⁴⁶, highlighting the need for approaches tailored to suit the functional dynamics of the system under study⁴⁷. With this in mind, we implemented an astrocyte manipulation protocol aligned to the temporal dynamics of VTA dopamine neurons and associated behaviors. Expression of ChR2 specifically in VTA astrocytes exploits the tight association between astrocyte cation permeability and GLT-1 function^{26-31,33}. By engaging chiefly ion gradients, optical stimulation recruits native astrocyte machinery in electrochemically realistic processes. This approach succeeds in expressing astrocyte-specific, temporally controlled dynamics that make relatively few assumptions about the relatively unknown cellular processes of VTA astrocytes. Finally, the use of light wavelengths minimizes reactive gliosis, which often confounds modulatory dynamics with long lasting inflammatory processes⁴⁸. It is notable that in vivo astrocyte manipulation produced real-time aversion that was readily reversed and spatially manipulated (Fig. 6b), signifying that ChR2 activation of astrocytes reflects dynamic modulation rather than long-lasting reactive processes. Optogenetic manipulation of astrocytes also affects only those afferents that are active during ChR2 photoactivation (Fig. 2-3, S5). Therefore, during our conditioned place paradigms only those neuronal inputs that are active during the paired conditioning session will be facilitated during laser activation.

Implications for pathophysiologies

As a core symptom of anxiety disorders, maladaptive avoidance is considered to be an underlying mechanism maintaining anxiety¹. Avoidance is a decision to refrain from potential negative outcomes at the expense of potential rewards. It is in this context that our finding is most relevant; VTA astrocyte GLT-1 can be manipulated to change inhibitory dynamics on dopamine neurons that interfere with the expression of conditioned place preference for reward. It is significant that the conditional loss of GLT-1 eradicates dynamical control of inhibition in the VTA and concurrently reduces avoidance behavior, but preserves approach to reward. Thus, separable pathways within the VTA drive behavioral responses to reward and

aversion⁹, and may be subject to distinct pathophysiologies that culminate in maladaptive learning processes¹. VTA astrocytes may therefore reflect a specific target for therapeutics, which have the added advantage of producing effects limited to activated synapses.

CONCLUSIONS

Our results establish a previously unknown, intra-VTA circuit mechanism specific to avoidance behavior through which astrocytes exert fast, dynamic control of dopamine neuron firing by modulating afferent glutamatergic drive on GABA neurons (glutamatergic afferents → astrocyte GLT-1 → GABA neuron EPSP → dopamine neuron IPSP → avoidance). We conclude that VTA astrocytes orchestrate temporal control of dopamine neuron firing, rendering them a decisive element in the circuit computation of avoidance, and promising targets for new therapeutic strategies to intervene in pathological disorders of behavior.

METHODS:

Animals: Male and female C57BL/6J mice, Vgat-ires-Cre mice (016962 Stock) and GLT-1^{f/f} (GLT-1^{flox/flox})³⁵ mice were used. All procedures were approved by the University of Texas at San Antonio Institutional Animal care and Use Committees in accordance with the National Institutes of Health guidelines.

Creation of AAV-TAS-gfaABC1D-ChR2-EYFP: With the creation of an abbreviated GFAP promoter that maintained astrocyte specificity³⁴, expression is amplified by using a transcriptional amplification strategy (TAS). This includes cloning a mini-CMV promoter driving expression of Gal4 binding domain fused with the p65 transcriptional activation domain on the opposite strand, and 5 concatenated Gal4 binding sites between the two promoters, mini-CMV and gfaABC1D⁴⁹. Using PCR, the TAS-gfaABC1D enhancer and promoter was amplified and isolated with AscI/SalI sites on the 5' and 3' ends, respectively. This fragment was subcloned into a AAV-CaMKII-ChR2-EYFP by digesting the plasmid with MluI/SalI to remove the CaMKII promoter and have compatible cohesive ends with the new promoter. The AAV vector was packaged and pseudo-typed with AAV5 at the UNC vector core.

Stereotaxic injections and fiber optic implantations: 8 to 12 week old mice were anesthetized using isoflurane anesthesia. Stereotaxic injections of different viruses (250 nL at a rate of 100 nl/min) were delivered to the VTA using the following coordinates relative to bregma AP: -2.6 to -3.2 ML: ±0.6 DV: -4.5. Mice received either AAV5/TAS-gfaABC1D-ChR2-eYFP or AAV5-GFA104-eGFP. Vgat-ires-Cre mice received injections of AAV5/gfaABC1D-ChR2-eYFP and AAV5/EF1α-DIO-eNpHR3.0-eYFP. GLT-1^{f/f} mice received injections of AAV5/gfaABC1D-ChR2-eYFP only or AAV5/gfaABC1D-ChR2-eYFP with AAV-gfaABC1D-Cre.

All mice were implanted with custom made fiber optic cannulas 100 μm above the injection site. Custom made cannulas were constructed using 1.25 mm diameter ferrule, 200 μm fiber optic cable with NA 0.39 and a two-part epoxy. The fiber optic cannulas were secured to the skull of each mouse using miniature screws and dental cement. Mice were singly housed and allowed to recover for 12 days before behavioral experiments were performed. Mice with virus and/or fiber optics outside of the VTA were excluded from analysis.

Immunohistochemistry: Electrophysiology experiments: Once recordings were completed, the slices were incubated in 4% paraformaldehyde (PFA) for 30 minutes and moved to phosphate buffered solution (PBS) with .02% sodium azide for long-term storage at 4°C.

Mice used for behavioral experiments were anesthetized and intracardially perfused with ice-cold PBS, followed by 4% PFA. The brains were removed and placed in 4% PFA overnight at 4°C. The brains were next rinsed with PBS and 100 μ M coronal slices containing VTA were collected. The slices were placed in PBS with .02% sodium azide for long-term storage at 4°C.

On day one slices were rinsed twice with PBS for ten minutes. Slices were blocked and permeabilized using 5% normal goat serum (NGS)/0.2% triton X-100 in PBS for two hours at room temperature. Slices were incubated overnight at 4°C with the following primary antibodies: Rabbit anti NeuN (1:1000, ABCAM), chicken anti Tyrosine hydroxylase (1:500, AB9702), Rabbit anti EAAT-2 (1:500, AB41621), Mouse anti GABA (A0310) in 1% normal goat serum/0.1% triton X-100 with PBS. On day two, slices were washed three times, for ten minutes with PBS/0.05% triton X-100. Afterwards the slices were incubated with the following secondary antibodies: goat anti-rabbit Alexa 488 (1:1000, A11034) or Alexa 546 (1:1000, A11035), goat anti-chicken Alexa 488 (1:1000, A11039), Alexa 546 (1:1000, A11040) or 647 (1:1000, A21449) in 1% normal goat serum/0.1% triton X-100 in PBS for 2 hours at room temperature. Finally, the slices were washed three times for ten minutes with PBS/0.05% triton X-100 at room temperature and mounted onto slides using Fluoromount-G (0100-20). Bright field and fluorescence images for fiber and opsin placement were obtained using a CCD camera on a fluorescent stereoscope. Sections containing the ventral midbrain were imaged using a Zeiss confocal at 20X magnification with 1.0 μ m thick optical sections. Each confocal image was obtained using identical settings for gain, laser and pinhole size. Images were then analyzed using ImageJ FIJI software.

Open field test: Mice were placed in a custom-made plastic rectangular box (50 cm X 30 cm) and the box was divided into a center and outer zone. Mice were allowed to freely explore for 30 minutes. Anymaze (Stoelting) video tracking system was used to track the distance each mouse travelled and how much time they spent in

each zone for all behavioral experiments.

Real-time place preference: Mice were placed in a custom-made plastic rectangular box (50 cm X 30 cm) with no distinguishing cues. One side of the chamber was randomly designated to be the side where the lasers would be activated. Individual mice were initially placed in the chamber and allowed to explore before beginning the experiment. During the 30-minute session the laser would be activated (1Hz: 0.5 s pulse duration, 15-20 mW) each time the mouse entered the laser-paired side of the chamber, and would be turned off when the mouse crossed back into the non-stimulation side of the chamber. The difference score was calculated by taking the time the mouse spent in the Laser side minus time in the No Laser side.

Mice expressing ChR2 or GFP in astrocytes were connected to a 473 nm laser using a 1x1 rotary joint. For mice expressing ChR2 in astrocytes and NpHR3.0 in GABA cells we used a 2x1 rotary joint connected to 405 nm and 593 nm laser. This allowed us to activate either ChR2 or NpHR3.0 individually or together. The same set up was used for all behavior experiments.

Laser Conditioned Place Avoidance (Laser CPA): Laser CPP experiments were performed over a four-day period using a two-chamber CPP apparatus (Med Associates) with each chamber consisting of distinct cues. Any mouse with a strong initial preference for either chamber (defined as a mouse spending more than 75% of the time in either chamber) was discarded from analysis. On day 1 (pre-test), mice were placed in one of the two sides and allowed to freely explore the entire apparatus for 30 minutes. During days 2 and 3 (conditioning) mice were confined to one of the two chambers (counterbalanced across all mice) and received optical stimulation (0.5 seconds pulse, 18 mW) once a minute for 30 minutes, or no stimulation. During the no stimulation session mice were connected the same as during the laser session, but the laser was off. A minimum of 4 hours after the first training session mice were placed into the other side of the chamber and the treatment reversed. Day 4 (post-test), mice were allowed to freely roam the apparatus for 30 minutes. The difference score was calculated by taking the time each mouse spent on the laser paired side in the post-test minus the time spent in the pre-test.

Cocaine Conditioned Place Preference (cocaine CPP): A modified version of Laser CPA and the same chamber were used to perform cocaine CPP experiments. The pre-test and the post-test were performed identically, but the conditioning sessions were changed. During days 2 and 3 of conditioning, mice were confined to one of the two chambers (counterbalanced across all mice) and received an i.p. cocaine (15 mg/kg) injection paired with optical stimulation (0.5 seconds pulse, 18 mW) once a minute for 30 minutes, or i.p. saline injection with no laser stimulation. During both conditioning sessions mice were tethered to the patch cable. The difference score was calculated by taking the time each mouse spent on the cocaine/laser paired side in the post-test minus the time spent in the pre-test.

Brain slice preparation and electrophysiology: After completion of behavioral experiments, mice were deeply anesthetized with isoflurane followed by rapid decapitation. The brain was quickly removed and chilled in ice cold cutting solution containing (in mM): 110 cholineCl, 2.5 KCl, 1.25 NaH₂ PO₄, 7 MgCl₂, 0.5 CaCl₂, 10 dextrose, 25 NaHCO₃, and oxygenated with 95% O₂ -5%CO₂. 250 μ m horizontal brain slices containing VTA were incubated for 30 minutes at 35° C in a chamber filled with artificial cerebrospinal fluid (aCSF) and stored at room temperature for the remainder of the day. Slices were transferred to a recording chamber where they continuously received aCSF (33-35° C) at a rate of 2 ml per minute by a gravity-feed system. aCSF was composed of (in mM): 126 NaCl, 2.5 KCl, 1.25 NaH₂ PO₄, 2 MgCl₂, 2 CaCl₂, 10 dextrose, 25 NaHCO₃, was equilibrated using 95% O₂ -5%CO₂ and had a pH of 7.2.

Midbrain neurons and astrocytes were visualized using gradient contrast illumination through a 40X water-immersion lens attached to an Olympus BX51 upright microscope. Neurons were considered dopaminergic based on the following electrophysiological criteria: have a hyperpolarization-activated inward current, slow spontaneous firing frequency \leq 5 Hz and an action potential half-width \geq 1.5 ms. Dopamine (TH-positive) and GABA (GABA-positive) neurons filled with biocytin were further identified immunocytochemically (Fig. S2, S4). Astrocytes expressed GFP and were visualized with a 40X or 60X water-immersion objective on a fluorescent microscope capable of detecting GFP.

Whole cell recording pipettes with a tip resistance between 4-6 MOhm were pulled from borosilicate glass using a P-97 Flaming/Brown electrode puller (Sutter Instruments). For voltage clamp experiments recording pipettes were filled with internal solution containing (in mM): 110 d-gluconic acid, 110 CsOH, 10 CsCl₂, 1 EGTA, 10 HEPES, 1 ATP, 10 mM phosphocreatine. Pipettes used for current clamp recordings contained (in mM): 138 K-gluconate, 10 HEPES, 2 MgCl₂, 0.2 EGTA, 0.0001 CaCl₂, 4 Na-ATP, 0.4 Na-GTP.

Postsynaptic currents (PSC) were evoked by placing a 250 μ m bipolar stimulating electrode within 500 μ m of the neuron being recorded and applying a single pulse (0.05 ms). PSCs were isolated by voltage clamping the cells at -55 mV for EPSCs and at +10 mV for IPSCs. The effect astrocytes had on synaptic activity was tested by photoactivating ChR2 on astrocytes for 500 ms (constant stimulation) and evoking PSCs 400 ms in. ChR2 on astrocytes was stimulated using a 473 or 405 nm laser (10-20 mW). Afferent-mediated currents on astrocytes were obtained by applying 50 Hz electrical stimulation (20 pulses, 0.05 ms pulse width). Whole cell recordings were made using a Multiclamp 700B amplifier (Molecular Devices). Signals were digitized at 50 kHz and saved to a hard drive for analysis using Axograph X (Axograph).

Statistics: A student's two-tailed t-test was used when comparing between two groups. A One-way ANOVA with Tukey's post hoc test was used for comparisons across multiple groups. A P-value < 0.05 was used as our significance level for all tests.

Data availability: The data supporting these findings are available from the corresponding author upon request.

SUPPLEMENTARY FIGURES

Figure S1. ChR2-mediated currents in VTA astrocytes possess properties similar to electrical stimulation.

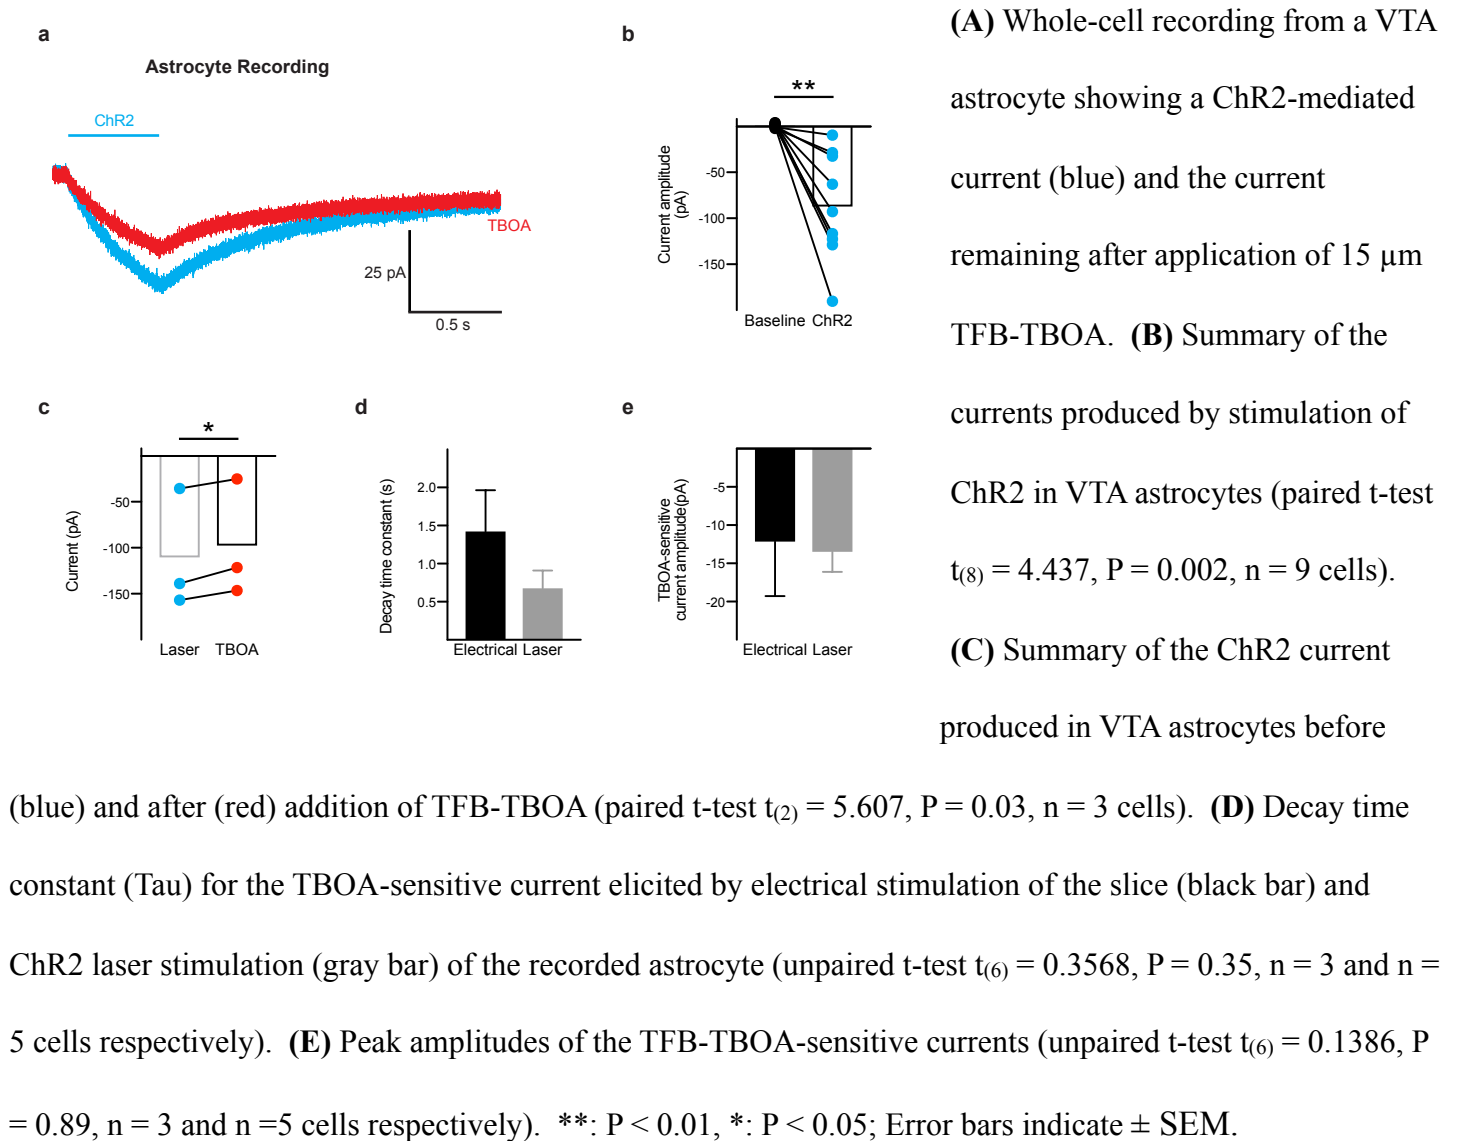

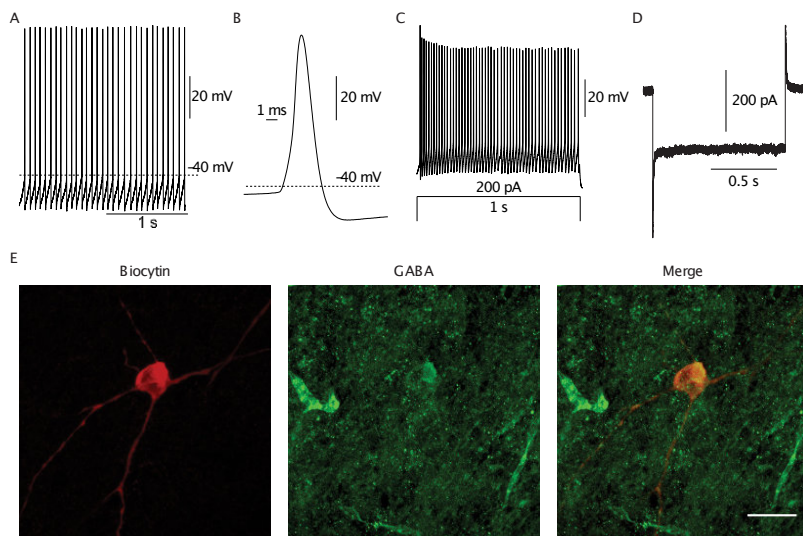

Figure S2. Identification of VTA GABA neurons.

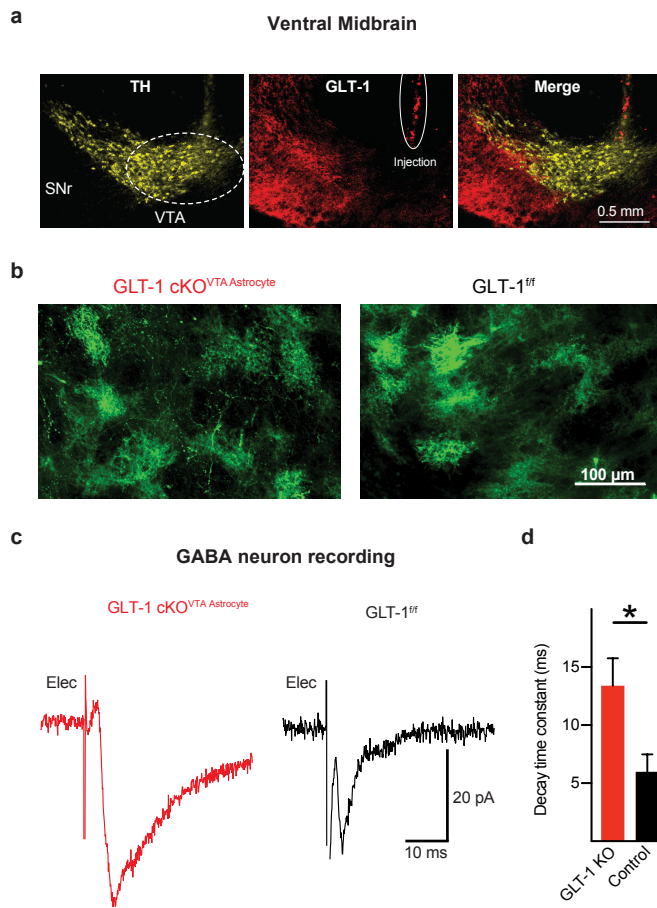

(A) Whole-cell current-clamp recording from a GABA neuron. **(B)** One of the action potentials from (A) was expanded to emphasize the action potential half width.

(C) Example recording showing no spike frequency adaptation in response to a 200 pA current injection. **(D)** Voltage clamp recording showing lack of I_h in response to

hyperpolarizing the cell from -60 mV to -120

mV for 1 second. **(E)** Immunohistochemistry images taken with a 40X objective showing a biocytin filled cell visualized using Alexa 594 (red) and GABA visualized using Alexa 488 (green). On the right is a merged image to show co-localization between the two fluorophores. Scale bar = 20 μ m.

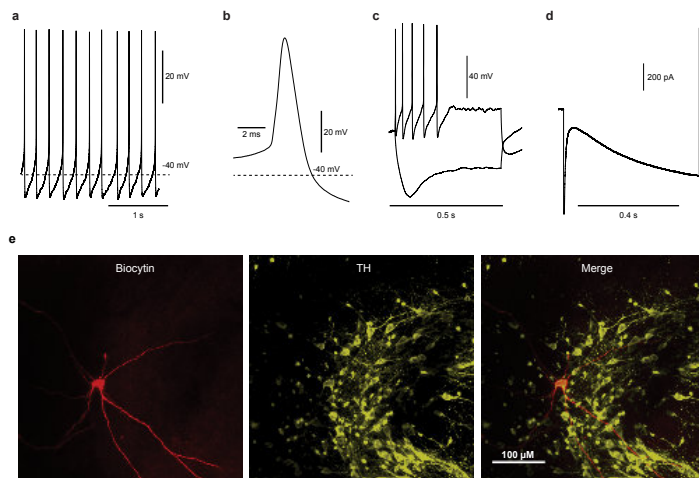

Figure S3. Loss of GLT-1 does not alter the expression pattern of Chr2, but does change the decay kinetics of excitatory currents on VTA GABA neurons.

(A) Image (4X objective) showing tyrosine hydroxylase (TH) positive cells (yellow) with GLT-1 staining (red), and placement of the injection within the ventral midbrain. On the right are the two images merged together showing lack of GLT-1 expression in the VTA. (B) 20X image showing Chr2 (green) expression in GLT-1 cKO and GLT-1^{f/f} mice. (C) Recordings from GABA neuron EPSC's in a GLT-1 cKO^{VTA Astrocyte} (red) and a GLT-1^{f/f} (black) mouse. (D) GLT-1 cKO^{VTA Astrocyte} mice (red) have a slower decay time constant compared to GLT-1^{f/f} mice (black), suggesting GLT-1 has been removed near GABA neurons (unpaired t-test $t_{(9)} = 2.531$, $P = 0.03$,

$n = 6$ and $n = 5$ cells respectively). *: $P < 0.05$; Error bars indicate \pm SEM.

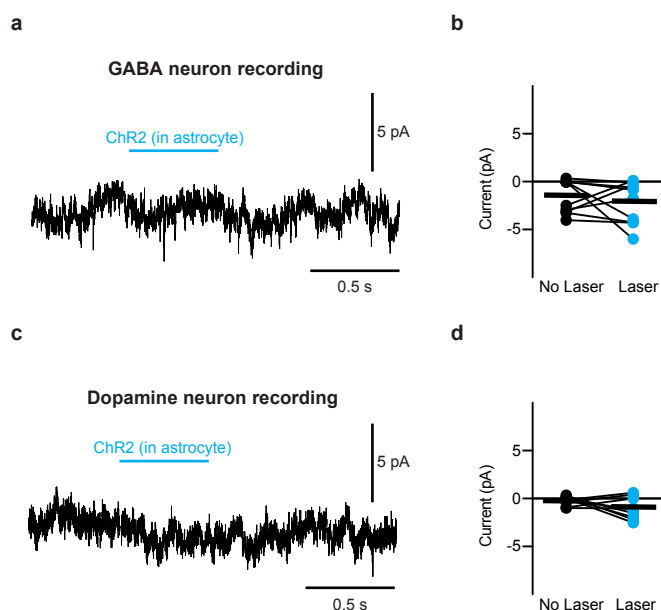

Figure S4. Identification of VTA Dopamine neurons.

(A) Whole-cell current-clamp recording from a dopamine neuron. (B) One of the action potentials from (A) was expanded to emphasize the wide action potential half width. (C) Example recording showing spike frequency adaptation in response to a 200 pA current injection and a characteristic sag in response to hyperpolarizing current injection (c; -200pA). (D)

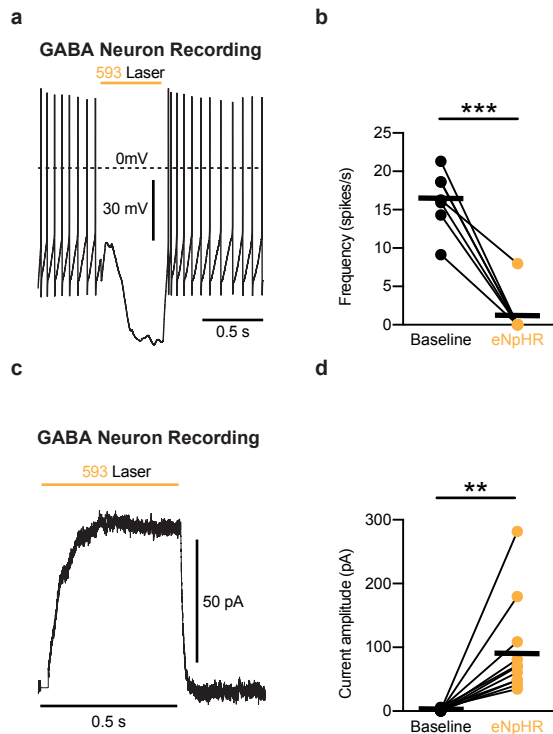

Developing current due to voltage clamp step. (E) Immunohistochemistry images (20X objective) showing a biocytin-filled cell (red) with overlapping tyrosine hydroxylase staining (yellow). On the right is a merged image showing co-localization of the two fluorophores, identifying the recorded neuron as TH-positive.

Figure S5. Astrocyte activation does not directly affect GABA or dopamine neurons.

(A) Recording from a VTA GABA and (C) dopamine neuron while activating astrocytes expressing ChR2 (500 ms constant light pulse). Summary data comparing the average holding current 100 ms before astrocyte stimulation with the last 100 ms of astrocyte stimulation for recordings from (B) GABA (paired t-test $t_{(9)} = 0.7458$, $P = 0.47$, $n = 10$ cells) and (D) dopamine neurons (paired t-test $t_{(8)} = 1.1728$, $P = 0.12$, $n = 9$ cells).

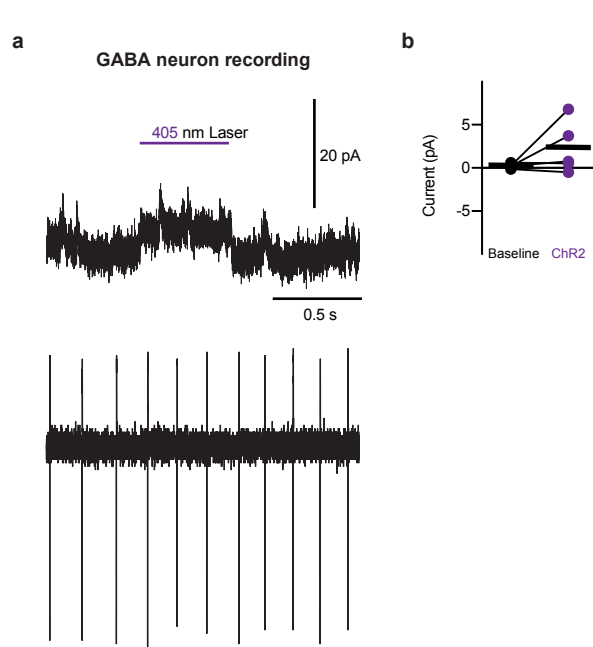

Figure S6. Photoactivation of eNpHR3.0 inhibits firing and produces an outward current in GABA neurons.

(A) Whole cell current-clamp recording from a GABA neuron obtained from a Vgat-Cre mouse expressing eNpHR3.0 in GABA neurons. Photoactivation of eNpHR3.0 prevents firing of action potentials in GABA neurons. (B) Summarized data showing the effect eNpHR3.0 (yellow) has on the firing of action potentials in GABA neurons (paired t-test $t_{(6)} = 8.141$, $P = 0.0002$, $n = 7$ cells). (C) Whole-cell voltage clamp recording from a GABA neuron where activation of eNpHR3.0 produces an outward current. (D) Summary of the currents generated by eNpHR3.0 (yellow) in GABA

neurons (paired t-test $t_{(10)} = 4.01$, $P = 0.002$, $n = 11$ cells). ***: $P < 0.001$, **: $P < 0.01$

Figure S7. Currents generated by 405 nm laser do not alter the firing pattern of GABA neurons

expressing eNpHR3.0.

(A) A voltage-clamp (top) and cell-attach recording from the same GABA neuron expressing eNpHR3.0 in a Vgat-Cre mouse. Photoactivation of eNpHR3.0 with a 405 nm laser with equivalent light intensity to that used in vivo does not change the firing frequency of GABA neurons. (B) Summary of the outward current produced by a 405 nm laser activating eNpHR3.0 (yellow) on GABA neurons (paired t-test $t_{(4)} = 1.523$, $P = 0.20$, $n = 5$ cells).

Figure S8. Astrocyte activation does not alter locomotor activity in real-time place preference or conditioned place preference assays.

(A) There was no difference in the total distance traveled between mice expressing GFP or ChR2 in VTA astrocytes during a 30 minute RTPP session

(unpaired t-test $t_{(15)} = 0.7177$, $P = 0.48$, $n = 8$ and $n = 9$ mice respectively). (B) Comparing the total distance traveled between mice expressing either ChR2, GLT-1 cKO with ChR2, or GFP in VTA astrocytes during laser activation (One-way ANOVA, $F_{(2,33)} = 2.203$, $P = 0.1264$). (C) Comparing the total distance traveled between mice expressing either ChR2, GLT-1 cKO with ChR2, or GFP in VTA astrocytes during cocaine + laser activation (One-way ANOVA, $F_{(2,27)} = 2.299$, $P = 0.1197$); Error bars indicate \pm SEM.

Supplementary Video 1.

ChR2 stimulation on VTA astrocytes elicits avoidance. Mouse receives ChR2 photoactivation of VTA astrocytes (1Hz: 0.5 s pulse duration, 15-20 mW) when venturing to the top half of the field. Movie (4X speed) is 15 s of the 30 minute session.

ACKNOWLEDGEMENTS

We thank C. Wilson and M. Higgs for helpful comments; P. Rosenberg (Boston Children's Hospital) for providing GLT-1^{fl/fl} mice. Funding: This research was supported by National Institutes of Health Grants MH079276 (CAP), MH113341 (CAP), DA030530 (CAP), DA033386 (MJW), DA042362(MJW), GM060655 (JAG), F31DA041303 (JAG) and National Science Foundation Grant HRD-1249284 (JAG). Imaging data collection was supported by Grant G12MD007591.

Contributions

JAG, JP, GB, and ES collected data. JAG, ES, JP, MJW, and CAP analyzed data. JAG, JP, GB, ES, and NC prepared animals and reagents. JAG, SAQ, and CAP wrote the paper.
