12

13 **Author Summary**

14 Neural circuits are formed by precise connections between axons. During axon
15 formation, the growth cone leads the axon to its proper target in a process called axon
16 guidance. Growth cone outgrowth involves asymmetric protrusion driven by extracellular
17 cues that stimulate and inhibit protrusion. How guidance cues regulate growth cone
18 protrusion in neural circuit formation is incompletely understood. This work shows that
19 the signaling molecule RHO-1 acts downstream of the UNC-6/Netrin guidance cue to
20 inhibit growth cone protrusion in part by excluding microtubules from the growth cone,
21 which are structural elements that drive protrusion.

22 **Abstract**

23 UNC-6/Netrin is a conserved axon guidance cue that directs growth cone
24 migrations in the dorsal-ventral axis of *C. elegans* and in the vertebrate spinal cord.
25 UNC-6/Netrin is expressed in ventral cells, and growth cones migrate ventrally toward
26 or dorsally away from UNC-6/Netrin. Recent studies of growth cone behavior during
27 outgrowth *in vivo* in *C. elegans* have led to a polarity/protrusion model in directed
28 growth cone migration away from UNC-6/Netrin. In this model, UNC-6/Netrin first
29 polarizes the growth cone via the UNC-5 receptor, leading to dorsally biased protrusion
30 and F-actin accumulation. UNC-6/Netrin then regulates protrusion based on this
31 polarity. The receptor UNC-40/DCC drives protrusion dorsally, away from the UNC-
32 6/Netrin source, and the UNC-5 receptor inhibits protrusion ventrally, near the UNC-
33 6/Netrin source, resulting in dorsal migration. UNC-5 inhibits protrusion in part by
34 excluding microtubules from the growth cone, which are pro-protrusive. Here we report
35 that the RHO-1/RhoA GTPase and its activator GEF RHGF-1 inhibit growth cone
36 protrusion and MT accumulation in growth cones, similar to UNC-5. However, growth
37 cone polarity of protrusion and F-actin were unaffected by RHO-1 and RHGF-1. Thus,
38 RHO-1 signaling acts specifically as a negative regulator of protrusion and MT
39 accumulation, and not polarity. Genetic interactions suggest that RHO-1 and RHGF-1
40 act with UNC-5, as well as with a parallel pathway, to regulate protrusion. The
41 cytoskeletal interacting molecule UNC-33/CRMP was required for RHO-1 activity to
42 inhibit MT accumulation, suggesting that UNC-33/CRMP might act downstream of RHO-
43 1. In sum, these studies describe a new role of RHO-1 and RHGF-1 in regulation of
44 growth cone protrusion by UNC-6/Netrin.

45 **Introduction**

46 The connectivity of neuronal circuits is established through properly guided
47 axons which form functional synaptic connections. The growing axon is guided to its
48 target by the motile, actin-based growth cone at the tip of the growing neurite. Growth
49 cone response to extracellular guidance cues allows the axon to extend, retract, turn
50 and branch, regulated by the reorganization and dynamics of the actin and microtubule
51 cytoskeletons of the growth cone (DENT AND GERTLER 2003).

52 In *C. elegans* and vertebrates, the conserved laminin-like UNC-6/Netrin guidance
53 cue and its receptors UNC-40/DCC and UNC-5 direct dorsal-ventral axon outgrowth
54 (HEDGECOCK *et al.* 1990; ISHII *et al.* 1992; LEUNG-HAGESTEIJN *et al.* 1992; CHAN *et al.*
55 1996; LEONARDO *et al.* 1997; HONG *et al.* 1999; MONTELL 1999; SHEKARABI AND KENNEDY
56 2002; MOORE *et al.* 2007). UNC-6 is secreted by cells in the ventral nerve cord
57 (WADSWORTH *et al.* 1996), and growth cones grow toward UNC-6/Netrin (i.e. ventral
58 migration; attraction) and away from UNC-6/Netrin (i.e. dorsal migration; repulsion). The
59 prevailing model of UNC-6/Netrin-mediated axon guidance involves a ventral-to-dorsal
60 chemotactic gradient of the molecule, which growth cones interpret by migrating up or
61 down the gradient using the “attractive” receptor UNC-40/DCC or the “repulsive”
62 receptor UNC-5, respectively (TESSIER-LAVIGNE AND GOODMAN 1996; LAI WING SUN *et al.*
63 2011). However, this model has recently been challenged by studies in mouse spinal
64 cord showing that floorplate Netrin is dispensable for commissural axon guidance, and
65 that ventricular expression is important, possibly in a close-range, haptotactic event
66 (DOMINICI *et al.* 2017; VARADARAJAN AND BUTLER 2017; VARADARAJAN *et al.* 2017;
67 YAMAUCHI *et al.* 2017).

68 Recent studies of growth cones during their formation and outgrowth *in vivo* in *C.*
69 *elegans* suggest that UNC-40/DCC and UNC-5 each act in both attracted and repelled
70 growth cones. In the HSN neuron, which extends an axon ventrally, UNC-6/Netrin
71 controls the ventral accumulation of the UNC-40 receptor in the HSN cell body, and
72 UNC-5 acts to focus UNC-40/DCC ventrally (the statistically-oriented asymmetric
73 localization (SOAL) model) (KULKARNI *et al.* 2013; YANG *et al.* 2014; LIMERICK *et al.*
74 2017). Furthermore, our previous work with the VD growth cones that migrate dorsally
75 (repelled) suggests that UNC-6/Netrin first polarizes protrusion and F-actin to the dorsal
76 side of the growth cone via the UNC-5 receptor, and then regulates protrusion based on
77 this polarity (the polarity/protrusion model). UNC-5 inhibits protrusion ventrally, close to
78 the UNC-6/Netrin source, and UNC-40 stimulates protrusion dorsally, away from the
79 UNC-6/Netrin source, resulting in directed dorsal growth away from UNC-6/Netrin
80 (NORRIS AND LUNDQUIST 2011; NORRIS *et al.* 2014; GUJAR *et al.* 2018).

81 UNC-40/DCC drives growth cone lamellipodial and filopodial protrusion via the
82 small GTPases CDC-42, CED-10/Rac, and MIG-2/RhoG, the Rac-specific guanine
83 nucleotide exchange factor (GEF) TIAM-1, and actin cytoskeletal regulators Arp2/3,
84 UNC-34/Enabled and UNC-115/abLIM (GITAI *et al.* 2003; STRUCKHOFF AND LUNDQUIST
85 2003; SHAKIR *et al.* 2008; NORRIS *et al.* 2009; DEMARCO *et al.* 2012). UNC-5 inhibits
86 growth cone protrusion via the Rac GEF UNC-73/trio, CED-10/Rac and MIG-2/RhoG
87 (also used to drive protrusion), the FMO flavin monooxygenases which might act via
88 actin, and the actin and MT-interacting proteins UNC-33/CRMP and UNC-44/Ankyrin
89 (NORRIS AND LUNDQUIST 2011; NORRIS *et al.* 2014; GUJAR *et al.* 2017). UNC-5 also
90 restricts the accumulation of microtubule + ends in VD growth cones which have pro-

91 protrusive effects (GUJAR *et al.* 2018). Thus, in *unc-5* mutants, VD growth cones are
92 larger and more protrusive, display unpolarized protrusion including ventral protrusions,
93 display unpolarized F-actin around the periphery of the growth cone, and have
94 increased accumulation of MT + ends (NORRIS AND LUNDQUIST 2011; GUJAR *et al.* 2018).
95 This unregulated protrusion results in unfocused growth cones that fail to migrate
96 dorsally away from UNC-6/Netrin, causing the severe VD axon guidance defects seen
97 in *unc-5* mutants.

98 The Rho-family GTPases CED-10/Rac, MIG-2/RhoG, and CDC-42 control
99 neuronal protrusion (LUNDQUIST *et al.* 2001; STRUCKHOFF AND LUNDQUIST 2003;
100 DEMARCO *et al.* 2012; NORRIS *et al.* 2014). Here we dissect the role of RHO-1, the single
101 RhoA molecule encoded in the *C. elegans* genome, in regulation of VD growth cone
102 polarity and protrusion. *rho-1* RNAi results in early embryonic arrest, with a failure in
103 cytokinesis and severe morphological defects (SPENCER *et al.* 2001; BRINGMANN AND
104 HYMAN 2005; MORITA *et al.* 2005; MOTEGI AND SUGIMOTO 2006). We used cell-specific
105 expression of constitutively-active RHO-1(G14V) and dominant-negative RHO-1(T19N),
106 and cell-specific RNAi of *rho-1* and found that RHO-1 inhibited growth cone protrusion
107 and MT + end accumulation. RHO-1 did not, however, affect polarity of protrusion or F-
108 actin. We also found that the RHO-1 activator RHGF-1, a RHO-1 GTP exchange factor
109 of the LARG family (YAU *et al.* 2003; CHEN *et al.* 2014), was required to inhibit protrusion
110 and MT + end accumulation similar to RHO-1. Genetic interactions with UNC-5
111 signaling and UNC-33/CRMP suggest that RHGF-1 and RHO-1 might act downstream
112 of UNC-5 and in parallel to other regulators of protrusion and MT + end accumulation.
113 These studies also revealed that RHO-1 requires UNC-33/CRMP to prevent MT + end

114 accumulation. In sum, results reported here show that RHGF-1 and RHO-1 are key
115 inhibitors of growth cone protrusion and MT + end accumulation and act with UNC-5 in
116 protrusion, but not growth cone polarity.

117

118 **Results**

119 **RHO-1 regulates growth cone protrusion but not polarity**

120 RHO-1 is the single RhoA homolog in *C. elegans*. Loss of *rho-1* leads to
121 embryonic lethality, with a failure in cytokinesis (JANTSCH-PLUNGER *et al.* 2000), and
122 perturbation of RHO-1 signaling in adults results in dysfunction in numerous neuronal
123 and non-neuronal functions leading to death (MCMULLAN AND NURRISH 2011). To
124 understand the role of RHO-1 in VD growth cone morphology, we constructed
125 constitutively-active G14V and dominant-negative T19N versions of RHO-1, and
126 expressed them in the VD/DD neurons using the *unc-25* promoter. Constitutively-active
127 *rho-1(G14V)* expression significantly reduced the VD growth cone area and shortened
128 filopodial protrusions as compared to wild-type (Figure 1A-B, D). In contrast, dominant-
129 negative *rho-1(T19N)* expression displayed significantly longer filopodial protrusions as
130 compared to wild-type VD growth cones (Figure 1A-B, E). Growth cone area was
131 increased, but not significantly so. These results indicate that RHO-1 activity inhibits
132 growth cone protrusion.

133 We used a transgenic RNAi approach to knock down *rho-1* in the VD/DD motor
134 neurons as previously described (see Materials and Methods) (ESPOSITO *et al.* 2007;
135 SUNDARARAJAN *et al.* 2014). Plasmids were generated to drive expression of sense and
136 antisense RNA fragments complementary to the *rho-1* under the control of the *unc-25*
137 promoter. Animals were made transgenic with a mix of the sense and antisense
138 plasmids, and the resulting transgenes were used in analysis. The average length of
139 filopodial protrusions and growth cone area were significantly increased in *rho-1(RNAi)*

140 (Figure 1A-B, F). These data suggest that RHO-1 normally inhibits VD growth cone
141 protrusion.

142 The polarity of filopodial protrusions was not affected by *rho-1(DN)* or *rho-*
143 *1(RNAi)*, as protrusions still displayed a dorsal bias similar wild-type (Figure 1G-I).
144 Thus, despite showing increased protrusion, the polarity of growth cone protrusion was
145 not affected by *rho-1*.

146

147 **RHO-1 is required to limit EBP-2::GFP puncta accumulation in VD growth cones.**

148 Previous studies indicate that in VD growth cones, F-actin accumulates at the
149 dorsal, protrusive edge of the growth cone and acts as a polarity mark to specify
150 protrusion in this region (Figure 2A and B) (NORRIS AND LUNDQUIST 2011; GUJAR *et al.*
151 2018). Furthermore, microtubule + ends are present in the growth cone and have a pro-
152 protrusive role (GUJAR *et al.* 2018). In wild-type, MT + ends are rare in VD growth cones
153 (~2 per growth cone) (Figure 2E and F) (GUJAR *et al.* 2018), and protrusion is tightly
154 regulated and localized to the dorsal leading edge at the site of F-actin accumulation
155 (Figure 2) (GUJAR *et al.* 2018).

156 VD growth cone F-actin was monitored using the VAB-1ABD::GFP reporter, and
157 MT + ends were monitored using EBP-2::GFP as described previously (NORRIS AND
158 LUNDQUIST 2011; GUJAR *et al.* 2018). Dominant-negative *rho-1(T19N)* and *rho-1(RNAi)*
159 had no effect on dorsally-polarized F-actin accumulation (Figure 2A and D), consistent
160 with no effects on growth cone polarity of protrusion (Figure 1). However, growth cone
161 EBP-2::GFP puncta number were significantly increased by dominant-negative *rho-*

162 *1(T19N)* and *rho-1(RNAi)* (Figure 2E, G, and H), consistent with increased protrusion in
163 these backgrounds.

164 Constitutively-active *rho-1(G14V)* resulted in fewer EBP-2::GFP puncta,
165 consistent with reduced growth cone protrusion (Figure 2E). F-actin polarity was also
166 abolished, with distribution along the periphery of the entire growth cone (Figure 2A and
167 C). Possibly, constitutive activation reveals a role of RHO-1 in F-actin polarity that is not
168 affected in reduction of function treatments. However, a similar effect on F-actin was
169 observed with constitutively-active Rac GTPases MIG-2 and CED-10 (GUJAR *et al.*
170 2018). Possibly, this effect on F-actin is a consequence of small growth cones with
171 severely-restricted protrusion, and not a direct role in F-actin organization. In sum, these
172 results suggest that RHO-1 normally restricts growth cone protrusion by preventing
173 accumulation of growth cone MT + ends.

174

175 **The RhoGEF RHGF-1 acts with RHO-1 to inhibit growth cone filopodial protrusion** 176 **and MT + end accumulation**

177 RHGF-1 is a PDZ RhoGEF with PDZ, RGS, C1, DH, and PH domains (Figure
178 3A). RHGF-1 is a RHO-1-specific GEF and acts with RHO-1 in neurotransmitter release
179 and axonal regeneration (YAU *et al.* 2003; HILEY *et al.* 2006; LIN *et al.* 2012; CHEN *et al.*
180 2014; ALAM *et al.* 2016). *rhgf-1(ok880)* is a 1170bp in frame deletion which removes a
181 large part of the DH domain and is predicted to have no RhoGEF activity (Hiley *et al.*,
182 2006), *rhgf-1(gk217)* is a 247bp in frame deletion which removes the C1 domain, and
183 *rhgf-1(gk292502)* produces a premature stop just before the C1 domain (Figure 3A).
184 *rhgf-1* mutants each displayed increased growth cone area and longer filopodial

185 protrusions compared to wild-type (Figure 3B-F). The dorsally-biased polarity of growth
186 cone protrusion was not significantly affected by *rhgf-1* mutation (Figure 3G-I). These
187 data indicate that RHGF-1 is normally required to limit the extent of growth cone
188 protrusion, but does not regulate growth cone polarity, similar to *rho-1*.

189 The *Drosophila* RHGF-1 homolog DRhoGEF2 is a key regulator of
190 morphogenesis and associates with the tips of growing MTs and exhibits plus end
191 tracking (ROGERS *et al.* 2004). In *C. elegans*, RHGF-1 associates with MTs and initiates
192 an axon regeneration pathway (Chen *et al.*, 2014). *rhgf-1* mutant VD growth cones
193 displayed significantly increased numbers of EBP-2::GFP puncta (Figure 4A-C), but
194 caused no significant defects in F-actin organization, similar to *rho-1* knockdown (Figure
195 4D-F). These results indicate that RHGF-1 might act with RHO-1 to inhibit growth cone
196 protrusion by excluding MT+ ends from entering the growth cone periphery.

197 The results above indicate that the VD growth cones of activated *rho-1(G14V)*
198 displayed reduced protrusion, and that those of *rhgf-1* loss of function were overly-
199 protrusive. The VD growth cones of activated *rho-1(G14V)* double mutants with *rhgf-1*
200 loss of function resembled the small, inhibited growth cones of *rho-1(G14V)* alone
201 (Figure 5A-E), with a significant reduction in filopodial length and growth cone area as
202 compared to *wild-type* and *rhgf-1* mutants alone (Figure 5A-E). Similarly, double
203 mutants of *rhgf-1* and *rho-1(G14V)* showed a significant decrease in the average
204 number of EBP-2 puncta in the growth cone similar to *rho-1(G14V)* alone (Figure 6A-D).
205 VAB-10ABD::GFP distribution in these double mutant growth cones also resembled
206 activated *rho-1(G14V)* with F-actin distributed randomly all across the growth cone
207 (Figure 6E-H). That activated RHO-1(G14V) was epistatic to *rhgf-1* loss of function is

208 consistent with RHO-1 acting downstream of RHGF-1 in limiting growth protrusion and
209 EBP-2 accumulation in VD growth cones.

210

211 **Activated *myr::unc-40* and *myr::unc-5* require RHGF-1**

212 Previous studies showed that UNC-6/Netrin signaling via the heterodimeric UNC-
213 40/UNC-5 receptor is required for inhibition of growth cone protrusion in UNC-6/Netrin
214 repulsive axon guidance (NORRIS AND LUNDQUIST 2011; NORRIS *et al.* 2014). Constitutive
215 activation of UNC-40 and UNC-5 using myristoylated versions of the cytoplasmic
216 domains of UNC-40 and UNC-5 (*myr::unc-40* and *myr::unc-5*) in the VD neurons result
217 in small growth cones with few or no filopodial protrusions (GITAI *et al.* 2003; NORRIS AND
218 LUNDQUIST 2011; NORRIS *et al.* 2014). Loss of *rhgf-1* significantly suppressed inhibition
219 of filopodial protrusion and growth cone size caused by *myr::unc-40* and *myr::unc-5*
220 (Figure 7).

221 *myr::unc-40* and *myr::unc-5* growth cones show a significant decrease in the
222 average number of EBP-2::GFP puncta in the VD growth cones as compared to wild-
223 type (Figure 8A-C) (GUJAR *et al.* 2018). Double mutants of *rhgf-1* with *myr::unc-40* and
224 *myr::unc-5* resembled *rhgf-1* mutants alone, with significant increases in protrusion and
225 MT+ end accumulation (Figure 8A, D). Similar to activated Racs and RHO-1(G14V), F-
226 actin is distributed throughout the small growth cones in activated *myr::unc-5* and
227 *myr::unc-40* (Figure 8E-G). *rhgf-1* mutation restored dorsal polarity of F-actin (Figure 8E
228 and H). In sum, the growth cones of *rhgf-1* double mutants with *myr::unc-5* and
229 *myr::unc-40* resembled those of *rhgf-1* mutants alone: increased protrusion and EBP-2
230 puncta accumulation, but normal dorsal F-actin polarity. These data indicate that RHGF-

231 1 is required for the inhibitory effects of *myr::unc-40* and *myr::unc-5* on growth cone
232 protrusion and EBP-2::GFP puncta accumulation.

233

234 **Activated RHO-1 does not suppress *unc-5* loss of function**

235 *unc-5* loss of function results in unpolarized, overly-protrusive VD growth cones.

236 Excess MT + ends accumulate in *unc-5*, and dorsal polarity of F-actin accumulation and

237 thus protrusion is lost (NORRIS AND LUNDQUIST 2011; GUJAR *et al.* 2018). Activated *rho-*

238 *1(G14V)* expression did not suppress the large growth cone area and long filopodial

239 protrusions seen in *unc-5* mutants (i.e. double mutants resembled *unc-5* alone) (Figure

240 9). Furthermore, we observed no significant change in EBP-2::GFP and VAB-

241 10ABD::GFP distribution in the VD growth cones as compared to *unc-5* mutants alone

242 (Figures 10 and 11).

243

244 **Activated RHO-1 suppresses *unc-33/CRMP* loss of function**

245 The Collapsin-response mediator protein (CRMP) UNC-33 and the Ankyrin-like

246 molecule UNC-44 are required for inhibition of growth cone protrusion of activated

247 *myr::unc-40* and *myr::unc-5*. Loss of *unc-33* and *unc-44* results in VD growth cones

248 resembling *unc-5* mutants, with increased protrusion, increased MT + end

249 accumulation, and loss of F-actin dorsal polarity (NORRIS *et al.* 2014; GUJAR *et al.* 2018).

250 Double mutants of *unc-33* and *rho-1(G14V)* resembled those of activated *rho-*

251 *1(G14V)* mutants alone, with a significant decrease in growth cone area and filopodial

252 protrusions (Figure 11). Despite reduced protrusion and smaller growth cone size, EBP-

253 2::GFP puncta accumulation was increased in double mutants of *unc-33* and *rho-*

254 *1(G14V)* (Figure 12). By contrast, double mutants of *unc-44* with *rho-1(G14V)*
255 resembled *unc-44* mutants, with excessive growth cone filopodial as evidenced with
256 increased filopodial length and growth cone area, as well as an increase in EBP-2
257 puncta distribution (Figures 11 and 12). Double mutants of *unc-33* and *unc-44* with *rho-*
258 *1(G14V)* showed no significant change in F-actin distribution as compared to single
259 mutants alone (Figure 13). These complex interactions reveal a differentiation of
260 function between UNC-33/CRMP and UNC-44/Ankyrin in interaction with RHO-1 in
261 growth cone morphology regulation.

262

263 **Discussion**

264 Previous studies indicate that directed outgrowth of the VD growth cones away
265 from UNC-6/Netrin involves a polarity/protrusion mechanism (NORRIS AND LUNDQUIST
266 2011; NORRIS *et al.* 2014; GUJAR *et al.* 2018). UNC-6/Netrin first polarizes protrusion to
267 the dorsal side of the growth cone, and then regulates the extent of growth cone
268 protrusion, with the receptor UNC-40 stimulating protrusion dorsally and the UNC-5
269 receptor inhibiting protrusion ventrally, resulting in directed dorsal growth away from
270 UNC-6/Netrin. Growth cone polarity is reflected in F-actin polarity, with F-actin
271 distribution biased to the dorsal side of the growth cone (i.e. the protrusive side). Growth
272 cone protrusion correlates with the presence of MT + ends, and MTs are pro-protrusive
273 in the VD growth cones (GUJAR *et al.* 2018). UNC-6/Netrin, its receptors UNC-5 and
274 UNC-40, Rac GTPases, and UNC-33/CRMP all regulate both growth cone polarity and
275 protrusion (NORRIS AND LUNDQUIST 2011; NORRIS *et al.* 2014; GUJAR *et al.* 2018). UNC-5
276 and UNC-33 normally inhibit growth cone protrusion in part by restricting MT + end
277 accumulation in growth cones (GUJAR *et al.* 2018).

278 Our results here show that the small GTPases RHO-1 and the Rho Guanine
279 nucleotide Exchange factor RHGF-1 mediate inhibition of growth cone protrusion and
280 are required to limit MT+ -end accumulation in growth cones, similar to UNC-5 and
281 UNC-33. However, RHO-1 and RHGF-1 had no effect on growth cone polarity (i.e.
282 mutants did not affect dorsally-biased distribution of filopodial protrusion and F-actin).
283 Thus, RHO-1 and RHGF-1 specifically affect VD growth cone protrusion, and not
284 polarity. Activated RHO-1 was epistatic to *rhgf-1* loss of function (i.e. growth cones in
285 double mutants displayed inhibited filopodial protrusions and a significant reduction in

286 EBP-2 puncta distribution similar to activated *rho-1* alone), consistent with the known
287 role of RHGF-1 as an upstream Rho activator.

288 Genetic studies suggest a complex interaction of RHO-1 and RHGF-1 with UNC-
289 5 and UNC-33. The data are consistent with the idea that RHO-1 and RHGF-1 act in the
290 UNC-5 pathway as well as in a parallel pathway (RHGF-1 was required for the effects of
291 activated MYR::UNC-5, but activated RHO-1 did not suppress *unc-5* loss of function)
292 (Figure 13). Additionally, activated RHO-1 suppressed the large, protrusive growth
293 cones of *unc-33* loss-of-function, but did not decrease MT + end accumulation in these
294 small growth cones. This suggests that UNC-33 might act downstream of RHO-1 in MT
295 accumulation, and that RHO-1 has an UNC-33-independent role in protrusion. While we
296 do not fully understand the nature of these interactions at this point, our data clearly
297 show that RHO-1 and RHGF-1 interact with UNC-6/Netrin signaling to regulate growth
298 cone protrusion and MT organization during growth cone outgrowth.

299

300 **RHO-1 regulates growth cone protrusion and EBP-2 distribution**

301 Expression of activated RHO-1(G14V) resulted in VD growth cones with a
302 marked decrease in growth cone protrusion and EBP-2 puncta distribution (Figures 1
303 and 2). Expression of the dominant negative form of RHO-1(T19N) in the VD neurons
304 and *rho-1(RNAi)* resulted in increased protrusion and EBP-2::GFP accumulation. MT+ -
305 ends in the growth cone periphery (Figures 1 and 2). Notably, neither dominant-
306 negative RHO-1(T19N) or *rho-1(RNAi)* resulted in altered growth cone polarity and F-
307 actin dorsal bias (Figures 1 and 2), suggesting that RHO-1 might specifically affect
308 growth cone protrusion but not polarity.

309 Previous work has identified roles of the Rho GTPases in regulation of both
310 microtubules and actin (WITTMANN AND WATERMAN-STORER 2001). RhoA has been
311 shown to regulate formation of contractile actin structures such as stress fibers and
312 promote stabilization of microtubules (COOK *et al.* 1998; ETIENNE-MANNEVILLE AND HALL
313 2002) through actomyosin contraction. In cultured growth cones, RhoA is involved in F-
314 actin retrograde flow, wherein actin filaments in the periphery undergo constant
315 retrograde transport to growth cone body (LIN AND FORSCHER 1995; LIN *et al.* 1996;
316 ZHANG *et al.* 2003; VAN GOOR *et al.* 2012). RhoA activates RhoA kinase (ROCK), which
317 activates contractility by phosphorylating the regulatory myosin light chain (MLC). This
318 actin retrograde flow is thought to restrict MTs from the growth cone through physical
319 association with these actin filaments undergoing retrograde flow, thereby reducing
320 leading edge protrusion resulting in growth cone collapse and retraction (ZHANG *et al.*
321 2003; GALLO 2004). Growth cone advance can occur when this actin-MT linkage is
322 disrupted or when actin becomes attached to the substrate (the “clutch” hypothesis)
323 (NICHOL *et al.* 2016) resulting in anterograde flow over the anchored actin filaments.
324 One hypothesis explaining our results is that, in VD growth cones, RHO-1-mediated
325 retrograde flow of actin restricts MT + ends from the growth cones, and when RHO-1
326 activity is reduced, more MTs enter the growth cones resulting in increased growth cone
327 protrusion.

328

329 **The Rho GEF RHGF-1 acts with RHO-1 to inhibit growth cone protrusion and MT**
330 **accumulation**

331 Loss of *rhgf-1* resulted in increased growth cone protrusion and accumulation of
332 EBP-2::GFP, similar to but more pronounced than dominant-negative RHO-1(T19N)
333 and *rho-1(RNAi)* (Figures 3 and 4). Furthermore, *rhgf-1* mutants had no effect on growth
334 cone polarity of protrusion or F-actin distribution (Figure 4). RHGF-1 might be an
335 activator of RHO-1 to inhibit growth cone protrusion and MT accumulation. Consistent
336 with this idea, activated *rho-1* was epistatic to *rhgf-1* loss-of-function (i.e. activating
337 RHO-1 bypasses the need for RHGF-1). Growth cones in these double mutants
338 displayed inhibited protrusion and reduction in MT distribution similar to activated *rho-1*
339 alone, suggesting that RHGF-1 acts as an upstream RHO-1 regulator in this process
340 (Figure 5 and 6).

341 Previous studies in *Drosophila* S2 cells have shown that the RHGF-1 homolog,
342 DRhoGEF2, induces contractile cell shape changes by regulating myosin II dynamics
343 via Rho1 pathway. Furthermore, DRhoGEF2 associates with tips of growing MTs and
344 travels to the cell cortex (ROGERS *et al.* 2004). In *C. elegans*, RHGF-1 functions through
345 Rho and ROCK to activate the MAPKKK DLK-1 during MT disruption, triggering
346 synaptic branch retraction and overgrowth of PLM neurites ultimately leading to
347 neuronal remodeling (CHEN *et al.* 2014). Possibly, RHGF-1 activates RHO-1 to mediate
348 a potential retrograde flow of F-actin to restrict MT accumulation in the growth cone.

349

350 **RHGF-1 is required for the inhibitory effects of MYR::UNC-5 and MYR::UNC-40**

351 *rhgf-1* loss-of-function suppressed the inhibitory effects of activated *myr::unc-40*
352 and *myr::unc-5* on growth cones. Double mutant growth cones resembled those of *rhgf-*
353 *1* alone, with increased protrusion and EBP-2::GFP puncta (Figure 7 and 8). That

354 RHGF-1 is required for the effects of constitutively active MYR::UNC-40 and
355 MYR::UNC-5 suggest that RHGF-1 acts downstream of MYR::UNC-5 and MYR::UNC-
356 40. However, it is possible that RHGF-1 defines a parallel pathway. In any event, the
357 inhibitory effects of MYR::UNC-5 and MYR::UNC-40 require functional RHGF-1.

358

359 **Activated RHO-1(G14V) cannot compensate for loss of UNC-5 in growth cone**
360 **inhibition**

361 Receptors to several attractive or repulsive guidance cues signal through
362 complex pathways through the Rho family of small GTPases to direct changes in growth
363 cone cytoskeletal organization (LUO 2002; GOVEK *et al.* 2005), and Rho activity is
364 thought to be induced by “repulsive” cues (GUAN AND RAO 2003). Loss of the UNC-
365 6/Netrin receptor *unc-5* has been shown to cause excessively large VD growth cones
366 with increased protrusion and excess EBP-2::GFP accumulation (NORRIS AND
367 LUNDQUIST 2011; GUJAR *et al.* 2018).

368 If RHO-1 is activated by UNC-5, we expect that activated *rho-1(G14V)* would be
369 epistatic to *unc-5* loss-of-function. This was not the case, as growth cones of *rho-*
370 *1(G14V); unc-5(lof)* double mutants resembled those of *unc-5(lof)* alone, with increased
371 protrusiveness and EBP-2::GFP accumulation (Figure 9 and 10). Possibly, loss of UNC-
372 5 affects multiple parallel pathways, including RHO-1, and activation of the RHO-1
373 pathway alone cannot compensate for loss of UNC-5. Alternately, RHO-1 might act in
374 parallel to UNC-5. That RHGF-1 function is required for the effects of activated
375 MYR::UNC-5 and MYR::UNC-40 suggests that RHGF-1 (and by extension RHO-1)
376 might, in part, act in the UNC-5 pathway directly.

377

378 **UNC-33/CRMP is required for activated RHO-1(G14V) restriction of EBP-2::GFP**

379 Previous studies have shown that the *C. elegans* UNC-33/CRMP is required in a
380 pathway downstream with Rac GTPases for inhibition of growth cone protrusion in
381 response to UNC-6/Netrin (NORRIS *et al.* 2014). *unc-33* loss-of-function mutants show
382 large protrusive growth cones with excess EBP-2 accumulation in the growth cones,
383 similar to *unc-5*. While activated RHO-1(G14V) did not suppress the excessively-
384 protrusive growth cones of *unc-5* mutants, it did suppress those of *unc-33* (Figure 11).
385 Protrusion of growth cones of *rho-1(G14V); unc-33* double mutants resembled *rho-*
386 *1(G14V)* alone (i.e. protrusion was reduced and growth cones were small).

387 Interestingly, despite their small size, inhibited *unc-33; rho-1(G14V)* growth
388 cones displayed increased EBP-2 puncta compared to wild-type animals, but
389 significantly lower than *unc-33* mutants alone (Figure 12). Thus, activated RHO-
390 1(G14V) can fully suppress excess protrusion, but not EBP-2::GFP accumulation, of
391 *unc-33* mutants. Together, these results suggest that UNC-33 is required for activated
392 RHO-1(G14V) to restrict MTs from growth cones. They also suggest that RHO-1 has a
393 role in protrusion that is independent of MT accumulation, as protrusion was reduced in
394 *rho-1(G14V); unc-33* double mutants despite excess MT accumulation.

395 UNC-44/Ankyrin is required to properly localize UNC-33/CRMP to the axons
396 (MANIAR *et al.* 2011), and mutants are phenotypically indistinguishable in the VD growth
397 cones (both are required to polarize protrusion and F-actin and to inhibit protrusion and
398 EBP-2::GFP accumulation) (NORRIS *et al.* 2014; GUJAR *et al.* 2018). However, *unc-44*
399 loss was completely epistatic to activated RHO-1(G14V), including both protrusion and

400 EBP-2::GFP accumulation. This suggests that UNC-44/Ankyrin has a role that is
401 independent of UNC-33/CRMP involving non-MT-based regulation of protrusion. The
402 FMO flavin monooxygenases inhibit growth cone protrusion with UNC-5 (GUJAR *et al.*
403 2017), possibly in an actin-based manner similar to MICAL (HUNG *et al.* 2010; HUNG *et*
404 *al.* 2011). Possibly, UNC-44/Ankyrin acts in this pathway or another independently from
405 UNC-33/CRMP.

406

407 **Summary**

408 Our results show that RHO-1 and the Rho activator GEF RHGF-1 are required to
409 inhibit VD growth cone protrusion and to restrict EBP-2::GFP puncta accumulation in
410 growth cones, possibly downstream of the UNC-6/Netrin receptor UNC-5. One potential
411 scenario for how these molecules interact is shown in Figure 13. UNC-5 might activate
412 RHGF-1 and thus RHO-1, and UNC-33/CRMP might then be required to exclude MTs
413 from growth cones in response to RHO-1 activation.

414 CRMP interactions with Rho, actin, and microtubules have been documented in
415 other systems. In cultured mammalian neurons, CRMP interacts with F-actin and with
416 tubulin dimers to promote microtubule assembly (FUKATA *et al.* 2002; ROSSLENBROICH *et*
417 *al.* 2005), and expression of CRMP2 can alter Rho-GTPase-driven neurite morphology.
418 Co-expression of Crmp-2 with activated Rho can promote cell spreading and neurite
419 growth and this function of Crmp-2 is regulated by Rho Kinase (HALL *et al.* 2001).
420 Furthermore, CRMP-2 has been shown to be phosphorylated by Rho Kinase II
421 (ARIMURA *et al.* 2000; ARIMURA *et al.* 2005) which disrupts the association of mature full-
422 length CRMP-2 with tubulin heterodimers so that tubulin cannot be transported to the

423 plus ends of microtubules for assembly (FUKATA *et al.* 2002) causing neurite retraction
424 and growth cone collapse (ARIMURA AND KAIBUCHI 2007). This reduced binding capacity
425 to tubulin by phosphorylated CRMP-2, can be reversed by inhibiting RhoA activity
426 (PETRATOS *et al.* 2008). Thus, RHO-1 may regulate growth cone protrusion and MT
427 distribution through the phosphorylation activity of UNC-33/CRMP possibly through the
428 same pathway or in parallel to it.

429 If RHO-1 is indeed involved in F-actin retrograde flow, the role of UNC-33 might
430 be to link F-actin to microtubules, such that in an *unc-33* mutant, MTs are not excluded
431 despite retrograde flow (including in the activated RHO-1(G14V) background). RHO-1
432 might have an additional non-UNC-33 and non-MT-dependent role in inhibiting
433 protrusion, along with UNC-44, possibly involving actin. In sum, RHO-1 is a key
434 negative regulator of growth cone protrusion and MT accumulation that acts specifically
435 in the protrusion aspect of the polarity/protrusion model of directed growth cone
436 migration away from UNC-6/Netrin.

437

438 **Materials and methods**

439 **Genetic methods**

440 Experiments were performed at 20°C using standard *C. elegans* techniques (BRENNER
441 1974). Mutations used were LGIV: *unc-5*(e53 and e152), *unc-33*(e204), *unc-44*(e362);
442 *lqls128* [*Punc-25::myr::unc-40*] LGX: *rhgf-1*(*gk217*, *ok880* and *gk292502*), *lqls170*
443 [*rgef-1::vab-10ABD::gfp*]. Chromosomal locations not determined: *lqls279* [*Punc-*
444 *25::ebp-2::gfp*] by integration of *lqEx809*, *lhls6* [*Punc-25::mCherry*], *lqls296* [*Punc-*
445 *25::myr::unc-5*], *lqls312* [*Punc-25::rho-1(G14V)*] by integration of *lqEx1043*, *lqls314*
446 [*Punc-25::rho-1(T19N)*] by integration of *lqEx1070*. Extrachromosomal arrays were
447 generated using standard gonadal injection (Mello and Fire, 1995) and include: *lqEx999*
448 and *lqEx1000* [*Punc-25::myr::unc-40*; *Pgcy-32::yfp*], *lqEx1131*, *lqEx1132*, *lqEx1133* and
449 *lqEx1134* [*Punc-25::rho-1 RNAi*; *Pgcy-32::yfp*], *OX347* [*Prgef-1::vab-10ABD::gfp*; *ttx-*
450 *3::rfp*]. Multiple (≥ 3) extrachromosomal transgenic lines of *Punc-25::ebp-2::gfp*, *Punc-*
451 *25::rho-1(G14V)* and *Punc-25::rho-1(T19N)* were analyzed with similar effect, and one
452 was chosen for integration and further analysis.

453

454 **Growth cone imaging**

455 VD growth cones were imaged and quantified as previously described (NORRIS AND
456 LUNDQUIST 2011). Briefly, animals at ~16 h post-hatching at 20°C were placed on a 2%
457 agarose pad and paralyzed with 5mM sodium azide in M9 buffer, which was allowed to
458 evaporate for 4 min before placing a coverslip over the sample. Some genotypes were
459 slower to develop than others, so the 16 h time point was adjusted for each genotype.
460 Growth cones were imaged with a Qimaging Rolera mGi camera on a Leica DM5500
461 microscope. Images were analyzed in ImageJ, and statistical analyses done with

462 Graphpad Prism software. As described in (NORRIS AND LUNDQUIST 2011; NORRIS *et al.*
463 2014), growth cone area was determined by tracing the perimeter of the growth cone
464 body, not including filopodia. Average filopodial length was determined using a line tool
465 to trace the length of the filopodium. Unless otherwise indicated, ≥ 25 growth cones were
466 analyzed for each genotype. These data were gathered in ImageJ and entered into
467 Graphpad Prism for analysis. A two-sided *t*-test with unequal variance was used to
468 determine significance of difference between genotypes.

469

470 **VAB-10ABD::*GFP* imaging**

471 The F-actin binding domain of VAB-10/spectraplaklin fused to GFP has been used to
472 monitor F-actin in *C. elegans* (BOSHER *et al.* 2003; PATEL *et al.* 2008). We used it to
473 image F-actin in the VD growth cones as previously described (NORRIS AND LUNDQUIST
474 2011). To control for variability in growth cone size and shape, and as a reference for
475 asymmetric localization of VAB-10ABD::*GFP*, a soluble mCherry volume marker was
476 included in the strain. Growth cones images were captured as described above. ImageJ
477 was used image analysis to determine asymmetric VAB-10ABD::*GFP* localization. For
478 each growth cone, five line scans were made from dorsal to ventral. For each line, pixel
479 intensity was plotted as a function of distance from the dorsal leading edge of the
480 growth cone. The average intensity (arbitrary units) and standard error for each growth
481 cone was determined. For dorsal versus ventral comparisons, the pixel intensities for
482 VAB-10ABD::*GFP* were normalized to the volumetric mCherry fluorescence in line
483 scans from the dorsal half and the ventral half of each growth cone. This normalized
484 ratio was determined for multiple growth cones, and the average and standard error for

485 multiple growth cones was determined. Statistical comparisons between genotypes
486 were done using a two-tailed *t*-test with unequal variance on these average normalized
487 ratios of multiple growth cones of each genotype.

488

489 **EBP-2::GFP imaging**

490 EBP-2::GFP has previously been used to monitor microtubule plus ends in other *C.*
491 *elegans* cells including neurons (SRAYKO *et al.* 2005; KOZLOWSKI *et al.* 2007; YAN *et al.*
492 2013). We constructed a transgene consisting of the *unc-25* promoter driving
493 expression of *ebp-2::gfp* in the VD/DD neurons. In growth cones, a faint fluorescence
494 was observed throughout the growth cone, resembling a soluble GFP and allowing for
495 the growth cone perimeter to be defined. In addition to this faint, uniform fluorescence,
496 brighter puncta of EBP-2::GFP were observed that resembled the EBP-1::GFP puncta
497 described in other cells and neurons. For each growth cone, the perimeter and filopodia
498 were defined, and the EBP-2::GFP puncta in the growth cone were counted. For each
499 genotype, the puncta number for many growth cones (≥ 25 unless otherwise noted) was
500 determined. Puncta number displayed high variability within and between genotypes, so
501 box-and-whiskers plots (Graphpad Prism) were used to accurately depict this variation.
502 The grey boxes represent the upper and lower quartiles of the data set, and the
503 “whiskers” represent the high and low values. Dots represent major outliers.
504 Significance of difference was determined by a two-sided *t*-test with unequal variance.

505 **Transgenic RNA-mediated gene interference (RNAi)**

506 We used a cell-specific transgenic RNAi approach as described previously (ESPOSITO *et al.*
507 *al.* 2007). Fragments of the *rho-1* coding region was amplified by PCR and inserted

508 behind the *unc-25* promoter in a plasmid (primer and plasmid sequences available upon
509 request). A “sense” and “antisense” orientation relative to the *unc-25* promoter was
510 isolated. An equimolar mixture of the sense and antisense plasmids was used to
511 construct transgenic animals. These transgenic animals were predicted to express both
512 sense and antisense RNAs driven by the *unc-25* promoter in the VD/DD motor neurons,
513 which was expected to trigger a double-stranded RNA response in these cells (RNAi).
514

654 Quantification of VD growth cone filopodial length and growth cone area in single and
655 double mutant animals as described in Figure 1. (A) Average filopodial length, in μm .
656 (B) Growth cone area in μm^2 . Error bars represent 2x standard error of the mean; n.s.,
657 not significant determined by two-sided *t*-test with unequal variance. (C-E) Fluorescence
658 micrographs of mutant VD growth cones. Arrows point to the growth cone and arrow
659 heads indicate representative filopodia. Scale bar: 5 μm .

660 **Figure 10. Genetic interactions of *rho-1* and *unc-5* in EBP-2::GFP accumulation**
661 **and F-actin polarity.** (A) Quantification of the number of EBP-2::GFP puncta in wild-
662 type and mutant animals as described in Figure 2E. n.s., not significant, determined by
663 two-sided *t*-test with unequal variance. (B-D) Fluorescence micrographs of EBP-2
664 distribution in the VD growth cones. Arrows indicate representative EBP-2::GFP puncta.
665 Dashed lines indicate the growth cone periphery. Dorsal is up and anterior is left. Scale
666 bar: 5 μ m. (E) The average dorsal-to-ventral ratio of GFP/mCherry from multiple growth
667 cones in wild-type, single and double mutant animals as described in Figure 2A. Error
668 bars represent 2x standard error of the mean; n.s. indicates no significant difference
669 between *unc-5* single mutants and double mutants determined by two-sided *t*-test with
670 unequal variance. (F-H) Representative images of VD growth cones with cytoplasmic
671 mCherry in red (a volumetric marker) and the VAB-10ABD::GFP in green. Areas of
672 overlap are yellow (arrows). (F) wild-type growth cone, (G) *rho-1(G14V)* growth cone,
673 (H) *unc-5(e53); rho-1(G14V)* double mutant VD growth cones with cytoplasmic mCherry
674 and VAB-10ABD::GFP expression. Dashed lines indicate the growth cone periphery.
675 Dorsal is up and anterior is left. Scale bar: 5 μ m.

676
677 **Figure 11. Genetic interaction *rho-1* with *unc-33* and *unc-44* in growth cone**
678 **protrusion.** (A-B) Quantification of VD growth cone filopodial length and growth cone
679 area in single and double mutant animals as described in Figure 1. (A) Average
680 filopodial length, in μ m. (B) Growth cone area in μ m². Error bars represent 2x standard
681 error of the mean; asterisks indicate the significant difference between the single mutant
682 and the double mutant phenotype (***p* < 0.001) determined by two-sided *t*-test with

683 unequal variance. n.s., not significant. (C-E) Fluorescence micrographs of mutant VD
684 growth cones as described in Figure 1. Arrows point to the growth cone and arrow
685 heads indicate representative filopodia. Scale bar: 5 μ m.

686

687 **Figure 12. Genetic interactions of RHO-1 and *unc-33* and *unc-44* in EBP-2::GFP**
688 **accumulation and F-actin polarity.** (A) Quantification of the number of EBP-2::GFP
689 puncta in wild-type and mutant animals as described in Figure 2E. Asterisks (*) indicate
690 the significant difference between single mutants and the double mutant (* $p < 0.01$).
691 Pound (#) indicates significant difference between wild-type and double mutant (# $p <$
692 0.01) determined by two-sided t -test with unequal variance. (B-D) Fluorescence
693 micrographs of EBP-2 distribution in the VD growth cones. (B) An *unc-33(e204)* growth
694 cone with increased *ebp-2* puncta. (D) A *rho-1(G14V)* small and inhibited growth cone
695 with significantly fewer *ebp-2* puncta. (E) An *unc-33(e204); rho-1(G14V)* small and
696 inhibited growth cone with increased *ebp-2* puncta. Arrows indicate representative EBP-
697 2::GFP puncta. Dashed lines indicate the growth cone periphery. Dorsal is up and
698 anterior is left. Scale bar: 5 μ m. (E) The average dorsal-to-ventral ratio of GFP/mCherry
699 from multiple growth cones in wild-type as described in Figure 2E. Error bars represent
700 2x standard error of the mean; n.s. indicates no significant difference between *unc-33*
701 and *unc-44* single mutants and their respective double mutants determined by two-
702 sided t -test with unequal variance. (F-H) Representative images of VD growth cones
703 with cytoplasmic mCherry in red (a volumetric marker) and the VAB-10ABD::GFP in
704 green. Areas of overlap are yellow (arrows). Scale bar: 5 μ m. Dashed lines indicate the
705 growth cone periphery. Dorsal is up and anterior is left.

706

707 **Figure 13. Possible interactions of RHO-1 in growth cone MT exclusion. UNC-5**

708 might activate RHGF-1 and thus RHO-1, and UNC-33/CRMP is required for RHO-1

709 activity to exclude MTs from the growth cone. UNC-5 might activate Rac GTPases in

710 parallel to drive MT exclusion via UNC-33/CRMP. UNC-5 might also engage a parallel

711 pathway to drive MT exclusion.
