10 Abstract

11 Different subtypes of Influenza A viruses cause different pathogenic phenotypes
12 after infecting human bodies. Direct binary interactions between viral proteins and
13 human proteins provide an important background for influenza viruses to cause complex
14 pathologies of hosts. Here, we demonstrated the different impacts on the TNF-α-induced
15 NF-κB activation of H1N1 and H5N1 virus proteins. By further examining the virus-host
16 protein-protein interactions (PPI), we found that the same segment protein of the H1N1
17 and H5N1 viruses target on different host proteins. We then performed a yeast
18 two-hybrid analysis of a highly pathogenic avian H5N1 influenza virus and human
19 proteins. Influenza-host protein-protein interaction networks of three strains of

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. It is made available under aCC-BY-NC-ND 4.0 International license.

influenza A viruses (including two other reported influenza-host PPI networks) were systematically compared and mapped on the network level and the pathway level. The results show subtype-specific characters of the influenza-host protein interactome, which may response for the specific pathogenic mechanisms of different subtypes of influenza viruses.

Importance

Influenza A virus (IAV) can cause contagious respiratory illness, namely influenza (flu). The symptoms of infections from different subtypes of IAVs vary from mild to severe illness. The mechanism of these different pathogenic phenotypes remains poorly understood. Our results show that the same NA and NP segments from H1N1 and H5N1 virus cause different impacts on the TNF-α-induced NF-κB pathway. Furthermore, we generated a yeast two-hybrid protein-protein interaction (PPI) network between H5N1 and human proteins. By systematically comparing the influenza-host PPI networks of three strains of IAVs, we show that different subtypes of IAVs target different human proteins and pathways, which may have led to different pathogenic phenotypes.

Introduction

Influenza A virus (IAV) belongs to the Orthomyxoviridae family. Its genome consists of eight segmented, negative-strand RNA [1-3]. IAV are further typed into many different

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. 38 subtypes based on the antigenicity of hemagglutinin (HA) and the neuraminidase (NA)
39 [4]. Currently, 18 HA(H1-H18) and 11 NA (N1-N11) subtypes have been identified in IAVs
40 [5]. Aquatic birds are considered to be the natural reservoirs of IAVs and the source of all
41 IAVs in other animals such as human, poultry, wild birds, swine, equine and so on [6-8].
42 Widespread hosts, the lack of proofreading activity of the viral polymerase during
43 genome replication and the segmented nature of genome enable IAVs rapidly evolve
44 though the accumulation of mutations and genome reassortment [9, 10], leaving an
45 increasing evolution diversity of the IAV and constantly emerged novel IAVs [11], which
46 poses a serious threat to human lives and economic development.

47 Different viruses may have evolved various mechanisms to co-opt host processes
48 and suppress host defenses, inducing different infectious phenotypic outcomes. H1N1 is
49 one of the main seasonal IAVs, which are annually recurrent and are mutually infectious
50 among human population[12, 13]. Highly pathogenic (HP) avian influenza virus (AIV)
51 H5N1 have jumped host barriers and caused human infections since 1997 [14].
52 According to the monitoring report from WHO, H5N1 AIVs have resulted in 860 human
53 infections and 453 deaths as of November 1, 2018 [15]. Constantly reported sporadic
54 human infectious with H5N1 and its high mortality warn us that H5N1 AIV may cause
55 serious epidemic worldwide. It is necessary to improve the epidemiological surveillance
56 and the research of pathogenic mechanism on these important subtypes of influenza
57 viruses.

58 Both H1N1 and H5N1 influenza viruses have posed tremendous health threats in

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

59 many regions worldwide, but their transmissibility, virulence and fatality are quite
60 different [16]. Although characterized by high transmissibility, the virulence and fatality
61 of the H1N1 influenza virus are relatively low. The reverse holds true for H5N1 influenza.
62 With a fatality rate that exceeds 60%, it is known to cause severe damage to the human
63 respiratory system, but the virus is not presently capable of efficient transmission from
64 human to human.

65 An important step to understand the pathogenesis of the pathogens is to
66 investigate the protein-protein interactions between the host and pathogens. Influenza
67 A viruses infect hosts through complex mechanisms, among which direct binary
68 interactions between influenza A viral proteins and host proteins play an important role
69 during the process influenza viruses invade hosts. The innate immune system is the first
70 barrier to prevent pathogen invasion. The NF-κB signaling pathway is an important part
71 of the innate immune system, which plays a key role in the induction of the innate
72 immune response against viral infection. The important role of NF-κB signaling pathway
73 in resisting virus invasion makes it a hot topic in current research [17-20]. In mammals,
74 there are two major NF-kB signaling pathways: the canonical NF-kB pathway and the
75 noncanonical NF-kB pathway [21, 22]. Under the stimulation of pathogenic microbial
76 infections or their induced inflammatory factors, NF-κB is normally activated by classical
77 signaling pathways [23]. Briefly, NF-κB dimers are retained in the cytoplasm by binding to
78 inhibitory IκB proteins, binding of certain ligands and cell surface receptors recruits
79 downstream adaptor proteins, then they recruit IKK complexes and lead to the activation

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

80 of IKK complexes [23, 24]. IKK complexes, especially the IKKβ subunit, phosphorylate two
81 serine residues of the IκB protein, resulting in ubiquitination and proteasome-dependent
82 degradation of the IκB protein, which releasing NF-κB into the nucleus to activate
83 downstream gene transcription [25, 26]. The non-canonical NF-κB signaling pathway
84 mainly activates the signal molecule NIK kinase, which in turn phosphorylates a complex
85 containing two IKKα subunits [27]. The IKKα complex phosphorylates and cleaves p100,
86 thereby promoting the form of p52/RelB dimerization which then activates transcription
87 of specific genes [28, 29].
88 Diverse bacterial and viral pathogens target NF-κB signaling pathway to evade host
89 immune defenses. Some viruses suppress NF-κB activation to dampen the host immune
90 responses to maintain latency [30]. For example, human bocavirus (HBoV) proteins NS1
91 and NS1-70 [31], the mumps virus (MuV) small hydrophobic protein (SH) [32] and
92 Molluscum contagiosum virus (MCV) protein MC005 [33] inhibit TNF-α-mediated
93 activation of NF-κB by reducing the phosphorylation of IKKβ, IκBα, and p65 as well as the
94 translocation of p65 into the nucleus. Some viral pathogens activate NF-κB for viral gene
95 expression, replication and spread. For example, the K15 protein of KSHV and the early
96 protein Nef of most primate lentiviruses enhances NF-κB activation to initiate proviral
97 transcription [34, 35]. Influenza A viruses can also interfere with antiviral responses by
98 regulating the NF-κB signaling pathway. Studies have shown that influenza virus proteins
99 interact with NF-κB to promote viral replication. For example, the IAV NS1 protein
100 specifically inhibits IKK-mediated NF-κB activation and production of the NF-κB induced

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. It is made available under aCC-BY-NC-ND 4.0 International license.

101 antiviral genes by physically interacting with IKK through the C-terminal effector domain
102 [36].

103 In this paper, we used the luciferase assay and the Co-immunoprecipitation
104 experiment to study how the NP and NA viral proteins of both HIN1 and H5N1 interact
105 with NF-κB signaling pathway. We found that the H1N1 NP has little impact on the
106 TNF-α-induced NF-κB transcriptional activation while the H5N1 NP inhibits the
107 TNF-α-induced NF-κB transcriptional activation by coimmunoprecipitating with IKKα.
108 Furthermore, the H5N1 NP suppresses the phosphorylation of IκBα, IKKα as well as the
109 translocation of p65 into the nucleus of infected A293 cells. We also found that the
110 H5N1 NA actives the IL-1β-induced NF-κB transcriptional activation by
111 coimmunoprecipitating with TAB2, while H1N1 NA inhibits the IL-1β-induced NF-κB
112 transcriptional activation by coimmunoprecipitating with IKKβ.

113 Then, we used a yeast two-hybrid approach to generate an influenza-host
114 protein-protein interaction network for a highly pathogenic avian H5N1 influenza virus
115 A/Goose/Jilin/hb/2003. In order to investigate the pathogenic conservations and
116 distinctions for different influenza virus subtypes, we introduced two other previously
117 reported influenza-host PPI networks (the H1N1 strain A/PR/8/34 and the H3N2 strain
118 A/Udorn/72) [37]. We systematically mapped and compared the pathogen-host protein
119 interactions between proteins from three strains of different influenza A virus subtypes
120 and human proteins. By identifying shared and distinct host-pathogen protein
121 interaction patterns for these influenza A viruses, we enlightened how they exploit

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. It is made available under aCC-BY-NC-ND 4.0 International license.

122 distinctive strategies to subvert cellular pathways toward disease progression.

123 # Results

124 **1 H5N1 NP and H1N1 NP have different impacts on TNF-α-induced NF-κB activation.**

125 Nucleoprotein (NP) is an important component of ribonucleoprotein (RNP) complex
126 playing crucial role in influenza virus life cycle together with other polymerase proteins
127 (PB1 and PA). At the onset of replication, NP functions as an adapter between the virus
128 and host cell processes to maintain the viral genome integrity. After release of RNP into
129 the cell cytoplasm, NP interacts with many macromolecules of cellular origin to facilitate
130 transcription, replication and translation of viral genome [6, 38].

131 TNF-α plays an important role in host defense against viral infection. During the IAV
132 infection, the elevated level of TNF-α is detected in serum. To determine the impact of
133 NP on the activation of the NF-κB pathway, we evaluated the impact of the H5N1 and
134 H1N1 NP coding sequence on NF-κB activation by using an NF-κB promoter reporter
135 system (Fig. 1A, Fig. 1B). Those results show that H5N1 NP inhibits TNF-α-induced NF-κB
136 transcriptional activation while the H1N1 NP has little impact on it, which confirming
137 that H5N1 NP has an inhibitory effect on NF-κB signaling pathway, but the specific site
138 and mechanism remain unclear. Then we searched for potential targets through the
139 luciferase assay. Those results (Fig. S1) show that the potential targets of H5N1 NP on
140 the NF-κB signaling pathway are IKKα and the complex of TAK. To decide the exact target

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

141 of H5N1 NP, we investigated whether the H5N1 NP protein physically interacts with IKKα
142 and the complex of TAK by the essay of Co-Immunoprecipitation. The results (Fig. 1C, Fig.
143 1D) show that there are protein-protein interactions between H5N1 NP and TAK1 and
144 IKKα in cells, indicating that the H5N1 NP inhibits the NF-kB signaling pathway by
145 targeting TAK1 and IKKα.

146 We then examined whether H5N1 NP can modulate its activation. The activation of
147 IKKα by phosphorylation is required to the phosphorylation of IκB. We tested whether
148 H5N1 NP played a role in inhibiting the phosphorylation of the IKKα. The results show
149 that the level of phosphor-IKKα in empty vector-transfected cells was more than that in
150 H5N1 NP-expressing cells (Fig. 1E), indicating that the H5N1 NP protein suppresses
151 TNF-α-mediated IKKα phosphorylation.

152 **2 H5N1 NA and H1N1 NA have different impacts on IL-1β-induced NF-κB activation.**

153 Neuraminidase（NA）is an integral membrane glycoprotein and a second major
154 surface antigen of the virion. NA cleaves terminal sialic acid from glycoproteins or
155 glycolipids. Thus, it functions to free virus particles from host cell receptors, to permit
156 progeny virions to escape from the cell in which they arose, and so facilitate virus spread
157 [6, 10].

158 We studied the differences in the impacts of the NA proteins of H5N1 and H1N1 NA
159 on the NF-κB signaling pathways using a similar method through an NF-κB promoter
160 reporter system. Reporter plasmid p NF-κB-luc and internal control plasmid pRL-TK,
161 together with pH5N1 NA and pH1N1 NA or empty vector, were cotransfected into 293T

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

162 cells. At 24h post-transfection, cells were mock-treated or treated with human IL-1β for
163 6h. The H5N1 NA clone significantly promoted IL-1β-stimulated NF-κB promoter activity
164 (Fig. 2A) while H1N1 NA has inhibitory impact on it (Fig. 2B). This result indicates that
165 H5N1 NA promotes IL-1β-induced NF-κB transcriptional activation while H1N1 NP
166 inhibits it.

167 The potential target of H5N1 NA on the NF-κB signaling pathway is the complex of
168 TAK (Fig. S2) while the potential targets of H1N1 NA on the NF-κB signaling pathway are
169 TAB2 and IKKβ (Fig. S3). Then we also studied the difference of interaction sites between
170 H5N1 NA and H1N1 NA with the NF-κB signaling pathway by the essay of
171 Co-Immunoprecipitation. The result is that H5N1 NA interacts with NF-κB signaling
172 pathway at TAB2 (Fig. 2C) while H1N1 NA interact with NF-κB signaling pathway at IKKβ
173 (Fig. 2D), which demonstrate that H5N1 NA and H1N1 NA have different sites that
174 interact with the NF-κB signaling pathway.

175 **3 Identification of Human Factors that Interacts with Influenza Viruses**

176 Then we seek to find out the virus-host relations of different subtypes of IAVs on a
177 larger scale by comparing the influenza-host PPI networks. We used a yeast two-hybrid
178 (Y2H) approach to identify direct binary interactions between proteins of an H5N1 strain
179 and human proteins. One hundred and seventy-seven pairwise interactions between the
180 8 viral proteins and the 140 human proteins were detected. (Fig. 3, Table S1).

181 Two previous reported influenza-host PPI network [37] were introduced in this
182 paper for comprehensively comparison of networks. The first network contains 135

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

183 pairwise interactions between the H1N1 strain A/Human/PR/8/34 ("PR8") and 87 human
184 proteins, and the second network covers 81 pairwise of interactions between the H3N2
185 strain A/Human/Udorn/72 ("Udorn") and 66 human proteins. Both of these two
186 pathogen-host networks were collected by using the Y2H approach. Our comparison and
187 network mapping are based on these three influenza-host PPI networks.

188 We generated a human protein-protein interaction network based on the BioGRID
189 interaction database [39], which contains 127950 interactions among 14924 human
190 proteins (only the physical binary interactions are selected). We define the proteins in
191 the human interaction network that directly interact with the influenza viruses as N1
192 proteins, and first neighbors of the N1 proteins are defined as N2 proteins. To quantify
193 the importance or the essentiality of proteins in the human PPI network, we use the
194 degree centrality and a new centrality measurement (named as NC) based on edge
195 clustering coefficient [40].

196 The network topological analysis shows that the viral proteins have a greater
197 average degree in the influenza-host interaction network compared to that of human
198 proteins in the human interaction network (Table 1). The N1 proteins and N2 proteins of
199 influenza viruses on average interact with more proteins in the human interaction
200 network than the others.

201 Based on the other centrality measure NC, both the N1 and N2 proteins of all the
202 three stains of influenza viruses score higher than the average score of the proteins in
203 the human interaction network, especially the N1 proteins of the H5N1 virus. In [41], the

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

204 authors proposed that pathogens may have evolved to interact with human proteins
205 that are hubs (those involved in many interactions) or bottlenecks (those central to
206 many pathways) [42] to disrupt key proteins in complexes and pathways. Our results also
207 support this hypothesis. The connection patterns above hold for all the three
208 influenza-host interaction networks, which implying that an influenza virus as a very
209 compacted pathogen has to maximum its function by interacting with many important
210 proteins in the hosts.

211 4 Different subtypes of influenza viruses show different virus-host interacting 212 patterns

213 Although all the three strains of influenza viruses share many topological characteristics
214 in the influenza-host interaction network, the direct interactors (N1 proteins) of different
215 subtypes of influenza viruses do not actually overlap much (Fig. 4A). Only 6 proteins
216 (Table 2) are shared by all the three strains as direct interactors. Table 2 has listed all the
217 6 proteins and their viral interactors of different subtypes of influenza viruses. Although
218 all the three strains of influenza viruses target directly at these six human proteins, the
219 viral proteins they used are different. For example, the viral interactor of the TRAF1
220 protein in the H5N1 strain is PB1, while the PR8 strain uses two different viral proteins
221 (NP, PB2) to interact with TRAF1.

222 Despite the three influenza viruses share few direct interactors, they have much
223 more in common at the N2 protein level (Figure 4B). In total, there are 829 proteins
224 shared by all the three influenza viruses.

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

225 We then mapped the host interactors to pathways that may involve in the infection
226 of influenza viruses. After filtering, four classes of pathways in the KEGG database [43]
227 were considered: the immune system pathways, the cell growth and death pathways,
228 the signal transduction pathways and pathways about inflammation. In total, sixty-five
229 pathways were selected (Table S2).

230 Fifty-five out of sixty-five pathways have shown to be in contact with one or more
231 strains of influenza viruses (Fig. 5), which prove the efficiency of our selection in
232 canonical pathways to consider. These include some previously reported pathways that
233 are related to influenza infection such as NF-kB, apoptosis, Wnt/β-catenin and MAPK
234 pathways. There are twenty-two out of sixty-five pathways shown to be involved in the
235 infection of all the three strains of influenza viruses.

236 Different subtypes of influenza viruses, though have few direct host interactors in
237 common, show much in common at the indirect interactor level (N2 proteins) and the
238 targeted pathway level. This fact implies that influenza viruses infect hosts by targeting
239 functional modules or protein complex in the host PPI network rather than focusing on
240 specific proteins to bind. More details of the relationships between influenza viruses and
241 host pathways show that different influenza viruses use different viral proteins to target
242 different host proteins in the pathways (Table S2).

243 # Discussion

244 During the course of an influenza virus infection, viral proteins interact with an array

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

245 of host proteins and pathways, which defines the viral-host relationships. Different
246 viral-host relationships lead to different pathogenesis of the virus. Human may be
247 infected by several subtypes of influenza viruses, including H1N1, H3N2, H5N1, H7N9,
248 H9N2. However, the symptoms of these infections vary from mild to severe illness. In
249 this paper, we tried to uncover the subtype-specific viral-host relationships by examining
250 the effects of viral proteins on the NF-κB signaling pathways. Furthermore, we
251 comprehensively compared the influenza-host PPI networks of three strains of virus in
252 different subtypes, including one that we constructed using the Y2H approach. The
253 results imply that different subtypes of influenza A virus use different viral proteins to
254 target on different human proteins and human cellular pathways, leading to different
255 pathogenic phenotypes.

256 NF-κB is critical for innate immune defense to cope with invading microbial
257 pathogens. Once there are viruses invading organisms, the host will manipulate the
258 NF-κB signaling pathway to clean up them. To survive, the microbial pathogens have
259 evolved various strategies to make use of the NF-κB signaling pathway to escape the
260 innate immune of the host. Influenza viruses can also manipulate the NF-κB signaling
261 pathway to promote their survival and replication. Interaction between influenza virus
262 and NF-κB signaling pathway is essential for its pathogenesis.

263 H1N1 and H5N1 influenza viruses both have the nucleoprotein and neuraminidase,
264 but their transmissibility, virulence and fatality are quite different [16]. Through our
265 studies, we found H5N1 NP inhibits TNF-α-induced NF-κB transcriptional activation while

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted bioRxiv a license to display the preprint in perpetuity. It is made available under aCC-BY-NC-ND 4.0 International license.

266 the H1N1 NP has little impact on it and H5N1 NA promotes IL-1β-induced NF-κB
267 transcriptional activation while H1N1 NP inhibits it. The results show subtype-specific
268 characters of the influenza-host protein interactome, which may response for the
269 specific pathogenic mechanisms of different subtypes of influenza viruses.

270 We systematically compared and mapped the influenza-host PPI network of three
271 stains of influenza viruses. Human interactors of different subtypes of influenza viruses
272 have shown to be of similar network topological parameters in the human PPI network.
273 Unlike the other two strains of viruses (PR8, Udorn), which are human-hosted, the highly
274 pathogenic avian H5N1 influenza virus used in this paper is originally an avian influenza
275 virus. This may explain the obvious differences in direct interactors and affected
276 pathways. The H5N1 strain tends to have more interactions with human proteins and
277 affect more cellular pathways than the other two strains. This implies that when avian
278 influenza viruses managed to cross the host barriers infect human, the interactions
279 between them are usually intense. However, for the viruses that have been circulating
280 for a long time in human, like H1N1 and H3N2 influenza viruses, the interactions
281 between the invader and the host become weaker.

282 The conservative patterns for all the three strains of influenza viruses at the N2
283 protein level and the pathway level highlight that pathogens have some common
284 attacking patterns to infect human. Some pathways that are related to all the three
285 strains of viruses are selected. The viral proteins employed to target at these conserved
286 pathways are different for different viruses, suggesting more subtype-specific pathogenic

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. It is made available under aCC-BY-NC-ND 4.0 International license.

287 mechanisms need more research work.

288 Materials and Methods

289 1. Antibodies and Reagents.

290 Antibodies for IκBα, α-Tubulin, Flag, HA, MyC, phospho-IκBα and phospho-IKKα
291 were purchased from Cell Signaling. Cell culture products were from Invitrogen and all
292 other chemicals were Sigma-Aldrich products unless noted.

293 2. Cell Culture, Transfection, and Luciferase Reporter Assays.

294 293T (human embryonic kidney) cells were cultured in Dulbecco's modified Eagle's
295 medium (DMEM, Gibco) supplemented with 10% heat-inactivated fetal bovine serum
296 (FBS, Gibco), 2mM L-glutamine, 100U/mL penicillin, and 100mg/mL streptomycin.
297 Transient transfections were performed with Lipofectamine 2000 (Invitrogen) according
298 to the manufacturer's instructions.

299 Luciferase activity was determined by using the dual luciferase assay kit (Promega)
300 according to the manufacturer's instructions.

301 3. Immunoprecipitation and Immunoblotting

302 Immunoprecipitation was performed using IP buffer (1% NP40, 50mM Tris-HCl [pH
303 7.5], 150mM NaCl, and CompleteTM protease inhibitor cocktail-EDTA (Roche)). Whole
304 cell extracts were prepared after transfection and incubated with indicated antibodies
305 together with Protein A/G beads (Roche) overnight. Beads were then washed 4 times

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. It is made available under aCC-BY-NC-ND 4.0 International license.

306 with IP buffer, and immunoprecipitates were eluted with SDS loading buffer (TransGen
307 Biotech) and resolved in SDS-PAGE gels. The proteins were transferred to PVDF
308 membrane (Bio-Rad) and further incubated with the indicated antibodies. The
309 antigen-antibody complexes were visualized by the ImmubilonTM chemiluminescent
310 detection kit (Millipore).

311 4.Statistical Analysis.

312 Analyses were done with the statistical software SAS/STAT. Data analysis over time
313 was undertaken by repeated-measures analysis with SAS/STAT. Differences were
314 considered statistically significant if the P value was <0.05.

315 5.Human Protein-Protein Interaction Network

316 We use all the protein-protein interaction for homo sapiens in the BioGRID
317 interaction database. The database version is 3.2.106. We choose all the physical
318 interactions in the database, while the genetic interactions are excluded. In total, the PPI
319 network contains 127950 interactions among 14924 human proteins.

320 6.Protein Centrality Analyses

321 Based on the human PPI network constructed, we calculated the degree of each
322 node in the network. And the NC centrality based on edge clustering coefficient are
323 calculated by using the following equation:

324 $$NC(v) = \sum_{u \in N_v} \frac{z_{v,u}}{\min(d_v - 1, d_u - 1)} \quad [40],$$

325 where $z_{v,u}$ denotes the number of triangles that include the edge actually in the

bioRxiv preprint doi: https://doi.org/10.1101/541177; this version posted February 5, 2019. 326 network, d_u and d_v are degrees of node u and node v, and N_v denotes the set
327 of all neighbors of node v.
328 7.KEGG Pathways
329 We download the KGML files at the KEGG pathway database for the pathways
330 belongs to the following categories: immune system pathways, the cell growth and
331 death pathways and the signal transduction pathways and pathways about inflammation.
332 Then, we parse these KGML files by using python programs to obtain the genes that
333 participated in each pathway.

334 Acknowledgments

335 This work was supported by the National Natural Science Foundation of China
336 (31800136), Beijing Nova Program (Z171100001117120), Independent Research Project
337 from State Key Laboratory of Pathogen and Biosecurity (SKLPBS1807) and Military
338 Medical Science and Technology Youth Development Program (18QNP037).

339 Author contributions

340 Hongguang Ren, Long Liang and Junjie Yue conceived and supervised the study.
341 Ting Song and Hongguang Ren designed the experiments. Yujie Wang, Ting Song and
342 Kaiwu Li performed the experiments. Hongguang Ren and Yuan Jin analyzed the data.
343 Hongguang Ren and Yujie Wang wrote the manuscript. Yujie Wang and Ting Song
344 contributed equally to this work.

Hippo signaling pathway
Fc epsilon RI signaling pathway
Prostate cancer
Leukocyte transendothelial migration
Ras signaling pathway
Cell adhesion molecules (CAMs)
Epithelial cell signaling in Helicobacter pylori infection
HIF-1 signaling pathway
Legionellosis
Toxoplasmosis
Proteasome
Complement and coagulation cascades
Inflammatory bowel disease (IBD)
NF-kappa B signaling pathway
Cytokine-cytokine receptor interaction
Non-alcoholic fatty liver disease (NAFLD)
MAPK signaling pathway
Rheumatoid arthritis
p53 signaling pathway
Viral myocarditis
Hematopoietic cell lineage
Asthma
Salmonella infection
Apoptosis
B cell receptor signaling pathway
NOD-like receptor signaling pathway
Phagosome
Tuberculosis
Toll-like receptor signaling pathway
Chemokine signaling pathway
Natural killer cell mediated cytotoxicity
T cell receptor signaling pathway
VEGF signaling pathway
PI3K-Akt signaling pathway
mTOR signaling pathway
Wnt signaling pathway
Notch signaling pathway
Cytosolic DNA-sensing pathway
Shigellosis
Viral carcinogenesis
Graft-versus-host disease
MicroRNAs in cancer
Rap1 signaling pathway
TNF signaling pathway
Systemic lupus erythematosus
ErbB signaling pathway
TGF-beta signaling pathway
Intestinal immune network for IgA production
Cell cycle
HTLV-I infection
Adipocytokine signaling pathway
Hedgehog signaling pathway
Jak-STAT signaling pathway
Amoebiasis
Type I diabetes mellitus

PB2 PB1 PA HA NP NA M1 M2 NS1 NS2
