Abstract

Klebsiella pneumoniae (Kp), one of the most common causes of healthcare-associated infections, increases patient morbidity, mortality and hospitalization costs. Kp must acquire nutrients from the host for successful infection. However, the host is able to prevent bacterial nutrient acquisition through multiple systems, including the innate immune protein lipocalin 2 (Lcn2) that prevents Kp iron acquisition by sequestering the siderophore enterobactin. To identify novel Kp factors that mediate evasion of nutritional immunity during lung infection, we undertook an InSeq study using a pool of >20,000 transposon mutants administered to *Lcn2+/+* and *Lcn2-/-* mice. Comparing mutant frequencies between mouse genotypes, this genome-wide screen identified the Kp citrate synthase GltA as potentially interacting with Lcn2, and this novel finding was independently validated. Interestingly, *in vitro* studies suggest that this interaction is not direct. Given that GltA is involved in oxidative metabolism, we screened the ability of this mutant to use a variety of carbon and nitrogen sources. The results indicated that the *gltA* mutant has a distinct amino acid auxotrophy and is unable to use a variety of carbon sources. Specifically, we show that *gltA* is necessary for growth in bronchioloalveolar lavage fluid, which is amino acid-limited, but dispensable in serum, which is amino acid rich. Deletion of *Lcn2* from the host leads to increased amino acid levels in bronchioloalveolar lavage fluid, and thus abrogates the loss of *gltA* during pneumonia in the *Lcn2-/-* background. GltA was also required for gut colonization, but dispensable in the bloodstream in a bacteremia model, demonstrating that deletion of *gltA* leads to an organ-specific fitness defect. Together, this study is the first to mechanistically describe a role for *gltA* in Kp infection and provide unique insight into how metabolic flexibility impacts bacterial fitness during infection.

Author Summary

The bacteria *Klebsiella pneumoniae* (Kp) is an important cause of infection in healthcare settings. These infections can be difficult to treat, as they frequently occur in chronically ill patients and the bacteria has the ability to acquire multiple antibiotic resistance markers. Kp is a common colonizer of the intestinal tract in hospitalized patients, and can progress to infections of the bloodstream, respiratory and urinary tract. However, the bacterial factors that allow Kp to replicate in these different body sites is unclear. In this study, we found that the Kp citrate synthase, GltA, enables bacterial replication in the lung and intestine by enhancing the ability of Kp to use diverse nutrients, in a mechanism known as metabolic flexibility. Kp lacking GltA require specific amino acids that are abundant in blood, but not other body sites. The work in this study provides novel insight into why Kp is a successful hospital pathogen that can colonize and infect multiple body sites.

Introduction

Extended spectrum beta-lactamase (ESBL)-producing *Enterobacteriaceae* and carbapenem-resistant *Enterobacteriaceae* (CRE) pose a serious public health threat due to their extensive antibiotic resistance. Many ESBL and CRE infections are healthcare-associated infections (HAIs), meaning they occur in long-term healthcare facilities and hospitals. *Klebsiella pneumoniae* (Kp) is an environmentally ubiquitous member of the *Enterobacteriaceae* family that can acquire antibiotic resistance genes [1], and thus, is a leading cause of ESBL-producing *Enterobacteriaceae* infections [2] and HAIs [3]. Strikingly, mortality rates in patients infected with antibiotic resistant Kp often exceed 40% [4]. Disturbingly, reports of hypervirulent clones of Kp acquiring mobile antibiotic resistance genes are becoming more frequent [5,6], posing a significant global threat to human health. As the efficacy of antibiotics diminishes and therapeutic options for patients infected with antibiotic resistant strains of Kp become increasingly limited, a better understanding of how Kp establish productive infections is necessary for the development of novel diagnostics and interventions to combat these dangerous bacteria.

To establish a productive infection, bacterial pathogens such as Kp must acquire nutrients from the host environment. Subsequently, metabolic flexibility frequently dictates the capacity of pathogens to invade different niches [7-10]. This flexibility is defined by the ability of a bacterial pathogen to categorically or conditionally acquire and utilize different metabolites. For example, *Salmonella enterica* serotype Typhimurium uses tetrathionate as an electron acceptor, providing a fitness advantage in the gut, whereas this advantage is not conferred in the spleen due to the lack of tetrathionate [11]. Interestingly, Kp potentially exhibits diversity in metabolism and nutrient acquisition, as indicated by the ability to cause a wide range of severe infections, including pneumonia, bacteremia, urinary tract infection, and pyogenic liver abscess [12]. Additionally, infectious Kp frequently originates

4

79 from sites of colonization [13-15], including the gut and nasopharynx [16,17]; however, the impact of

80 metabolic flexibility on Kp pathogenesis has not received significant attention.

81

82 Metabolites necessary for niche invasion by pathogens can be acquired directly from the host, through

83 the metabolic activity of other microorganisms within the host microbiome, or by *de novo* synthesis,

84 and limitation of access to these nutrients by the host is a universal means of impeding niche invasion

85 by bacterial pathogens [18-21]. For example, iron (Fe) is critical for niche invasion and subsequent

86 pathogenesis. The host sequesters ferrous iron (Fe^{2+}) by complexing with heme and ferric iron (Fe^{3+})

87 by complexing with transferrin, ferritin, or lactoferrin [18]. To overcome these complexes, bacterial

88 pathogens such as Kp encode a variety of proteins and small molecules to harvest sequestered iron,

89 including the family of low molecular weight chelators known as siderophores [22]. Consequently, the

90 host further prevents iron acquisition by sequestering bacterial siderophores with innate immune

91 molecules such as Lipocalin 2 (Lcn2). Lcn2 specifically binds the bacterial siderophore enterobactin

92 [23]; however, highly pathogenic bacterial strains encode alternative siderophores that circumvent this

93 activity. This strategy has been observed during Kp lung infection, wherein the presence of the

94 alternative Kp siderophore yersiniabactin is sufficient to overcome the effects of Lcn2 [24]. Interestingly,

95 Lcn2-bound Kp enterobactin has immunomodulatory effects [25], suggesting that the impact of Lcn2

96 during Kp infection is not limited to sequestration of enterobactin.

97

98 Beyond the well-characterized interaction between Lcn2 and siderophores during Kp infection, little is

99 known about other Lcn2-interacting Kp gene products in the context of nutrient acquisition. To discover

100 Kp genes that are conditionally essential in the presence of Lcn2, we undertook an InSeq experiment

101 comparing lung infection in *Lcn2+/+* and *Lcn2-/-* murine backgrounds. This revealed multiple

102 conditionally essential genes, including the citrate (Si)-synthase gene *gltA*. *In vitro* studies indicate that

103 the interaction between GltA and Lcn2 is indirect. Further analysis revealed that deletion of *gltA*

dramatically reduces metabolic flexibility, leading to arginine, glutamine, glutamate, histidine, and proline auxotrophy and a severe limitation of carbon utilization. This limitation of metabolic flexibility is partially complemented during lung infection by deletion of *Lcn2* due to an increase in amino acid concentrations in bronchioloalveolar lavage fluid, and GltA is dispensable for growth in amino acid-rich environments, such as serum. Finally, using multiple murine models of infection, we show that GltA is not necessary for bacteremia, but is necessary for gut colonization independent of the presence of *Lcn2*. Together, these data reveal how Kp metabolic flexibility, conferred by the citrate (Si)-synthase GltA, impacts compartmentalized fitness during infection.

Results

To comprehensively identify novel LCN2-interacting Kp gene products during Kp lung infection, we employed a previously described transposon library in the Kp strain KPPR1 [26,27]. To this end, *Lcn2+/+* and *Lcn2-/-* mice [28] were retropharyngeally inoculated with 1.4×10^6 CFU of a pool of ~25,000 transposon mutants (Fig S1A). Twenty-four hours after inoculation, mice were euthanized, lungs were collected and homogenized, and total lung CFU were collected for DNA extraction and InSeq analysis, as previously described [26]. After filtering, each sample had greater than 50 million reads corresponding to greater than 20,000 unique transposon insertions inside of open reading frames (Dataset S1). To identify LCN2-interacting Kp genes, the number of transposon insertion reads within each gene were compared between the *Lcn2+/+* and *Lcn2-/-* lung pools (mean reads per gene were 169 and 156, respectively). The log *Lcn2+/+:Lcn2-/-* insertion ratio of 1677 genes were significantly enriched or depleted after correction for multiple comparisons, including *entB* that is required to synthesize both enterobactin and the Lcn2-evading siderophore salmochelin (Dataset S1). A total of 49 genes had a fitness index greater or less than 3 standard deviations from the mean log *Lcn2+/+:Lcn2-/-* insertion ratio (Fig S1B, Dataset S1) and 43 of these genes were considered significant after correction for multiple comparisons (Fig S1C, Dataset S1, in bold). Of the 43 interrupted genes, 16 were enriched in the *Lcn2+/+* lung pool, indicating enhanced fitness when *Lcn2* is present, and 27 were enriched in the *Lcn2-/-* lung pool, indicating enhanced fitness when *Lcn2* is absent. Interestingly, the most common molecular function of genes enriched in both backgrounds was metabolism [29], accounting for 10 of 43 genes (23.3%), followed by membrane transport (6 of 43, 14.0%), including the putative siderophore transport system ATP-binding protein YusV, transcription factors (4 of 43, 9.3%), two-component systems (3 of 43, 6.9%), DNA repair and recombination (2 of 43, 4.7%), protein export (1 of 43, 2.3%), and quorum sensing (1 of 43, 2.3%). The molecular function of 16 (37.2%) of these genes has not been characterized. Three gene (*gltA*, *envZ*, and VK055_4417) enriched in the *Lcn2-/-* background were previously identified as fitness factors during Kp lung infection [26] (Dataset S1, in

7

italics). Five genes displayed a greater than 2-log enrichment in the *Lcn2-/-* lung pool, and one, VK055_1802, had a *P* value less than 10^{-300} (Fig S1C-D, Dataset S1). VK055_1802 is annotated as *gltA*, which encodes the citric acid cycle enzyme citrate (Si)-synthase [30]. Together, these data indicate that metabolism is critical for the interaction between KPPR1 and the host during lung infection.

To confirm the role of *gltA* during lung infection and its interaction with Lcn2, we constructed an isogenic *gltA* mutant in the KPPR1 background using the Lambda Red recombinase system [31] and complemented the gene in trans. The KPPR1Δ*gltA* strain displayed no growth defect compared to WT KPPR1 in nutrient-rich media (Fig S1E). This mutant was mixed 1:1 with its WT parent strain, then inoculated retropharyngeally in both *Lcn2+/+* and *Lcn2-/-* mice. As observed with InSeq data, the KPPR1Δ*gltA* displayed a significant fitness defect compared to the WT KPPR1 strain in the *Lcn2+/+* lung that was partially alleviated in the *Lcn2-/-* lung (Fig 1A). Given that citrate can act as a weak siderophore [32] and is a component of more complex siderophores [33,34], we hypothesized that deletion of *gltA* may inhibit novel stealth siderophore activity in the presence of Lcn2. To test this hypothesis, we grew a variety of KPPR1-derived strains in RPMI 10% resting human serum ± recombinant human Lcn2. The WT KPPR1 strain was not affected by the presence of Lcn2; however, the siderophore-null KPPR1Δ*entB*Δ*ybtS* strain [35] was unable to grow in Lcn2-free conditions, indicating the importance of siderophore function for KPPR1 growth. The enterobactin-dependent KPPR1Δ*iroA*Δ*ybtS* strain [36] was able to grow in Lcn2-free conditions, but unable to grow in the presence of Lcn2, validating the antagonistic relationship between enterobactin and Lcn2 (Fig 1B). Surprisingly, deletion of *gltA* had no impact growth in the presence of Lcn2 (Fig 1B), suggesting that the relationship between *gltA* and Lcn2 during lung infection is indirect.

Given that citrate (Si)-synthase performs an irreversible oxidation in the citric acid cycle, we next postulated that the relationship between *gltA* and Lcn2 is due to disruption of the TCA cycle. In addition

8

163 to oxidative metabolism, the TCA cycle provides a number of key carbon skeletons for the biosynthesis

164 of amino acids. To determine if loss of GltA affects Kp biosynthetic capabilities, we performed an

165 unbiased screen of carbon and nitrogen sources using the BioLog system to identify conditions

166 differentially permissive to KPPR1Δ*gltA* growth [37]. Both the WT KPPR1 and KPPR1Δ*gltA* were

167 cultured under 288 different conditions in triplicate, and growth was measured after 24 hours (Fig 2A,

168 Dataset S2). These experiments revealed 130 conditions in which WT KPPR1 significantly outgrew

169 KPPR1Δ*gltA*, two conditions in which KPPR1Δ*gltA* significantly outgrew WT KPPR1, nine conditions

170 where both strains grew equally well, and 147 conditions that did not support growth (Fig 2A, Dataset

171 S2). These data revealed that deletion of *gltA* in KPPR1 resulted in arginine, glutamine, glutamate,

172 histidine, and proline auxotrophy as indicated by the ability of these amino acids to support growth of

173 the KPPR1Δ*gltA* strain (Fig 2B, Dataset S2). Additionally, some dipeptides containing these residues

174 were partially or fully able to support growth of the KPPR1Δ*gltA* strain, whereas dipeptides without

175 these residues do not (Fig 2C, Dataset S2). To confirm these findings, we replicated these experiments

176 by growing the WT KPPR1, KPPR1Δ*gltA*, and pGltA complemented strains in minimal medium (M9)

177 containing glucose. When glucose is the sole carbon source, the KPPR1Δ*gltA* strain is unable to grow

178 but the addition of 10 mM glutamate fully restores growth (Fig 3A) and expression of *gltA* from a plasmid

179 complemented the mutant. This auxotrophy was fully or partially complemented by addition of 10 mM

180 glutamine, 2-oxoglutaric acid, and proline (Fig S2). Finally, the restoration of KPPR1Δ*gltA* growth in M9

181 medium containing glucose by addition of glutamate is dose-dependent (Fig 3B). These data show that

182 deletion of *gltA* induces specific amino acid auxotrophy.

183

184 Our data indicated that the deficiency of KPPR1Δ*gltA* in the *Lcn2+/+* lung is related to access to specific

185 amino acids necessary for complete growth. Bronchioloalveolar lavage fluid (BALF) is an ample

186 nutritional source for bacteria living in the upper respiratory tract, and measurable levels the amino

187 acids arginine, glutamate, 2-oxoglutaric acid, and proline are present in both human and mouse BALF

9

[38-41]. To determine if the differences in KPPR1Δ*gltA* fitness in *Lcn2+/+* and *Lcn2-/-* lungs is attributable to this source of nutrient, whole BALF was collected from uninfected mice and used as a bacterial growth medium. BALF from both mouse strains sustained growth of WT KPPR1 and KPPR1Δ*gltA* (Fig 4A); however, KPPR1Δ*gltA* grew significantly less well as measured by area under curve (AUC) analysis in *Lcn2+/+* BALF compared to *Lcn2-/-* BALF and WT KPPR1 cultured in *Lcn2-/-* BALF (Fig 4B). To determine if there are inherent differences in amino acid levels in the lungs of *Lcn2+/+* and *Lcn2-/-* mice that explain these differences in growth, we used gas chromatography–mass spectrometry to determine amino acid content in BALF from uninfected mice. *Lcn2-/-* BALF contains significantly higher levels of multiple amino acids and total protein content (Fig 4C, Dataset S3). Indeed, BALF from *Lcn2+/+* and *Lcn2-/-* are fully distinguishable based on their amino acid composition (Fig 4D). This increase in amino acid and protein content likely explains the difference between KPPR1Δ*gltA* fitness in the *Lcn2+/+* and *Lcn2-/-* backgrounds by functionally complementing the loss of *gltA*.

We next hypothesized that the loss of *gltA* would not affect bacterial growth in a physiologically relevant amino acid-rich environment, such as serum. To test this hypothesis, we grew the WT KPPR1 and KPPR1Δ*gltA* strains in minimal medium containing 20% heat-inactivated human serum. No differences in growth between the strains was observed (Fig 5A), and this result was recapitulated in both heat-inactivated and non-heat-inactivated murine sera (Fig S3). To determine if amino acid levels in human serum are sufficient to functionally complement the loss of *gltA*, we tested the growth of WT KPPR1 and KPPR1Δ*gltA* strains in minimal medium with plasma-level concentrations of glutamine, glutamate, and proline [42,43]. Indeed, serum-level concentrations of glutamine, glutamate, and proline were able to support growth of the KPPR1Δ*gltA* strain (Fig 5B). These data support the indication that amino acid auxotrophy induced by deletion of *gltA* is the basis of the loss of fitness observed in the amino acid poor environment of the *Lcn2+/+* lung.

213 The differential necessity of *gltA* for growth in BALF and serum led us to hypothesize that *gltA* is a

214 fitness factor in nutritionally deplete body sites, but not in nutritionally replete body sites. To test this

215 hypothesis, we first employed a peritoneal injection murine model of Kp infection. We injected *Lcn2+/+*

216 and *Lcn2-/-* mice with approximately 5×10^5 CFU of a 1:1 mix of WT KPPR1 and KPPR1Δ*gltA*

217 intraperitoneally. Twenty-four hours after inoculation, mice were euthanized, and blood, liver, spleen,

218 and lungs were collected. Solid organs were homogenized, and CFU was enumerated by dilution

219 plating. As observed in the lung infection model, KPPR1Δ*gltA* was at a competitive disadvantage

220 compared to WT KPPR1 in the *Lcn2+/+* lung, and this disadvantage was alleviated in the *Lcn2-/-* lung

221 (Fig 6A). Consistent with *ex vivo* serum growth, KPPR1Δ*gltA* was not competitively disadvantaged in

222 the blood of either mouse background but was less fit in the spleen and liver of *Lcn2+/+* mice (Fig 6A).

223 Next, we assessed the role of *gltA* in a different nutritionally replete body site: the large intestine. The

224 small intestine is thought to limit microbial density through absorption of nutrients; however, the large

225 intestine is nutritionally replete, wherein bacteria utilize complex carbohydrates to sustain high

226 population densities [44]. Results from our metabolic screen (Fig 2A, Dataset S2) indicate that the

227 KPPR1Δ*gltA* strain is unable to utilize multiple sugars, thus we hypothesized that the KPPR1Δ*gltA*

228 strain would be less fit in large intestine. To confirm our previous findings, we compared the growth of

229 WT KPPR1 and KPPR1Δ*gltA* in a variety of conditions wherein only a single sugar was provided as a

230 carbon source. Indeed, the KPPR1Δ*gltA* strain was unable to grow with multiple single sugars as carbon

231 source, conditions representative of the sugars available during gut colonization (Fig S4A-K). Finally,

232 we tested the role of *gltA* in an oral inoculation model of murine Kp infection. To this end, we gavaged

233 *Lcn2+/+* and *Lcn2-/-* mice with approximately 5×10^6 CFU of a 1:1 mix of WT KPPR1 and KPPR1Δ*gltA*.

234 Twenty-four hours after inoculation, mice were euthanized, cecal contents were collected, and CFU

235 was enumerated by dilution plating. In contrast to our previous experiments, we found that *gltA* is

236 necessary for cecal colonization in both the *Lcn2+/+* and *Lcn2-/-* background (Fig 6B). Together, these

237   data clearly display that *gltA* influences compartmentalized fitness during infection by limiting the ability

238   of Kp to use different nutrient sources for growth during infection.

239

Discussion

The ability of bacteria to utilize available nutrients upon encountering a new environment, referred to as metabolic flexibility, is critical for its survival and success. In order to achieve this end, bacteria must control highly interconnected metabolic pathways that are quickly activated based substrate availability in their local environment. Central carbon metabolism connects all pathways in the cell by providing carbon skeletons for biosynthesis of macromolecular building blocks and conversely represents convergence points for the catabolism of macromolecules. Central carbon metabolism is comprised of glycolysis, gluconeogenesis, the Entner-Doudoroff pathway, the pentose phosphate pathway, and the citric acid cycle. The research presented here identifies the citric acid cycle component, citrate (Si)-synthase (*gltA*), as a critical mediator of metabolic flexibility in Kp, and this metabolic flexibility drastically influences fitness during infection in a site-specific manner. Using multiple murine models of infection in *Lcn2+/+* and *Lcn2-/-* backgrounds, we show that *gltA* is a fitness factor during lung infection by direct and hematogenous routes, but not necessary for bacteremia. Additionally, *gltA* is necessary for gut colonization, which frequently precedes infection [12,13]. The necessity of *gltA* is determined by the nutrient composition of each respective body site, more specifically, access to amino acids that the bacteria cannot synthesize *de novo* without GltA. This is supported by the observation of differential fitness of KPPR1Δ*gltA* in the *Lcn2+/+* and *Lcn2-/-* lung, which have different endogenous levels of amino acids. Together, these data provide new insight into how Kp metabolic flexibility determines fitness during infection. The impact of this finding is highlighted by the fact that *gltA* is highly conserved among Kp strains. While the contributions of specific metabolic processes, such as iron acquisition [24,25,35,36,45-48], nitrogen utilization through urease activity [49], allantoin metabolism [50], and psicose metabolism [51] in Kp pathogenesis have been explored, this study is the first to reveal a role for central metabolism during Kp infection.

13

264   GltA is a type II citrate synthase, which are characteristically found in Gram-negative bacteria. The Kp

265   GltA is closely related to the citrate synthases of other members of *Enterobacteriaceae*, such as *S.*

266   *enterica* and *E. coli*, sharing 96% and 95% amino acid sequence identity, respectively. Interestingly,

267   the Kp genome has multiple genes annotated as *gltA*. Apart from VK055_1802, VK055_2057 is

268   annotated as *gltA* (hereafter *gltA2*). The *gltA2* gene is universally present in *Klebsiella spp.* but not in

269   other *Enterobacteriaceae* genera. I-TASSER 3D structure prediction [52-54] indicates that GltA2 is

270   structurally similar to GltA despite sharing only 60% and 58% amino acid sequence identity with KPPR1

271   GltA and *E. coli* str. K-12 substr. MG1655 GltA, respectively. Despite this structural similarity, our data

272   demonstrate that *gltA* and *gltA2* were functionally distinct, as the presence of *gltA2* was unable to

273   complement the loss of *gltA*. While the impact of *gltA2* on metabolic flexibility has yet to be explored, it

274   is beyond the scope of this study; however, the universal presence of *gltA2* in *Klebsiella sp*. but not in

275   other *Enterobacteriaceae* may provide a unique opportunity as a target for species and sub-species

276   level detections.

277

278   Our data indicate that the loss of *gltA* abrogates the *de novo* synthesis of L-glutamate and other key

279   carbon skeletons for biosynthesis of amino acids, which is essential to bacterial survival. Glutamate is

280   needed for ammonia assimilation and is the fulcrum of glutamine, proline, arginine, and histidine

281   biosynthesis [55]. In fact, glutamate and glutamine provide nitrogen for all nitrogen-containing

282   components of the bacterial cell, and approximately 88% comes from glutamate [56]. Studies in *E. coli*

283   have shown that glutamate is the most abundant intracellular metabolite, with an absolute intracellular

284   concentration of 96 mM [57]. Additionally, after conversion to its D-enantiomer, glutamate serves as a

285   component of bacterial peptidoglycan, which forms the cell wall and determines the rate of cell

286   elongation [58]. Thus, Kp lacking *de novo* synthesis of glutamate are incapable of proliferating unless

287   glutamate can be acquired exogenously. This is highlighted by the fact that growth of KPPR1Δ*gltA* in

288   M9 is rescued by the addition of glutamate in a dose-dependent manner. A complete restoration of

14

289 growth only occurs upon the addition of a sufficient amount of glutamate (Fig 3). Alternatively,

290 exogenous glutamine, proline, arginine, and histidine can facilitate growth through the central nitrogen

291 metabolic circuit or through production of glutamate through degradation [55]; however,

292 supplementation of 2-oxoglutaric acid at a high concentration was not sufficient for a complete

293 restoration of growth, suggesting a lack of transporting mechanism (Fig S2). Additionally, our data

294 demonstrate that dipeptides containing glutamate, glutamine, and histidine can support growth of GltA-

295 deficient Kp (Fig 2), suggesting that bacteria rely on scavenging dipeptides or polypeptides in the

296 course their colonization and infection. Taken together, our findings suggest that stratifying *in vivo*

297 environments as either nutritionally replete or deplete relative to the bacteria is apropos, and that a

298 systems biology approach of studying bacterial metabolic flexibility is beneficial for understanding the

299 lifestyle of pathogenic bacteria.

300

301 By maintaining high metabolic flexibility, pathogenic bacteria can invade multiple niches, and thus,

302 increase their chances of evolutionary success. For example, commensal *E. coli* living in the human

303 gut favor metabolic pathways that take advantage of the sugar-rich mucus lining [59,60], whereas

304 uropathogenic *E. coli* (UPEC) favor metabolic pathways that take advantage of the nitrogen-rich urinary

305 tract environment [61]. As predicted, deletions in glycolysis, pentose phosphate pathway, and the

306 Entner-Doudoroff pathway had little effect on fitness in the urinary tract environment, whereas specific

307 citric acid cycle components are necessary [9,62]. Similarly, *Legionella pneumophila* utilizes amino

308 acids as its primary carbon source during lung infection in immunocompromised patients [63]. Our data

309 suggests that metabolic flexibility plays a similar role for Kp as it does for *E. coli*, wherein the ability to

310 utilize mucin sugars is important for survival in the gut and the ability to utilize peptides and amino acids

311 is important for Kp survival during lung infection. As abrogation of glycolysis, pentose phosphate

312 pathway, and Entner-Doudoroff pathway enzymes do not impact UPEC survival in the urinary tract,

313 one would expect that abrogation of these pathways has little effect on Kp fitness in the lung. Indeed,

314 transposon interruptions of specific glycolysis (*pfkB*, VK055_3061 [*pgi*]*, tpiA*, *pyk*), pentose phosphate

315 pathway (*gnd*), and Entner-Doudoroff pathway (VK055_1337 [*tal1*], VK055_2566 [*tal3*], *edd*) enzymes

316 were not functionally complemented in the *Lcn2-/-* lung (Dataset S1). Correspondingly, one would

317 predict that specific citric acid cycle components are important for Kp fitness in the lung. Interestingly,

318 only two citric acid cycle enzymes, *gltA*, and the fumarate reductase subunits, *frdD*, were functionally

319 complemented in the *Lcn2-/-* lung; however, the fumarate reductase subunits (*frdA-C*) did not display

320 a similar phenotype (Dataset S1), and furthermore, these enzymes are only used during anaerobic

321 growth. Our previous InSeq study identified the citric acid cycle components *gltA*, *frdA*, and *frdC*, as

322 fitness factors during lung infection [26]. Accordingly, only one glycolytic enzyme (*pfkB*), no pentose

323 phosphate pathway enzymes, and no Entner-Doudoroff pathway enzymes were identified as fitness

324 factors in this study [26]. Surprisingly, interruption of the citric acid cycle genes *acnA* and *frdB* and the

325 Entner-Doudoroff pathway enzyme *tal1* resulted in enhanced fitness during lung infection in these

326 studies; however, the underpinnings of this phenotype have yet to be explored. Taken together, these

327 findings indicate that the oxidative citric acid cycle is beneficial for Kp lung infection, though under

328 specific nutrient conditions only parts of the cycle are necessary for complete fitness. Furthermore, our

329 findings highlight the importance of *gltA* to the metabolic flexibility of Kp during niche invasion in the

330 human host and lay the groundwork for more comprehensive studies aimed at understanding the

331 metabolic requirements for invasion of different body sites and the complex interactions between

332 different metabolic pathways in the context of infection.

333

334 Phenotypic metabolic flexibility has also been used to delineate closely related species of the *K.*

335 *pneumoniae* complex, which includes *K. pneumoniae*, *K. quasipneumoniae*, and *K. variicola*, as well

336 as Kp pathogenic lineages. *K. quasipneumoniae* is largely considered to be an opportunistic pathogen

337 that is frequently found as a colonizer [64], whereas *K. variicola* causes more serious infections [65].

338 The three members of this complex can be separated by their metabolic profile, wherein metabolism of

16

339 adonitol, psicose, tricarballylic acid, and hydroxyproline phenotypically separates Kp from *K.*

340 *quasipneumoniae* and *K. variicola* [66]. Moreover, the Kp strain used in this study, KPPR1, has been

341 shown to be more metabolically flexible than the less pathogenic Kp strain MGH 78578 [67]. Finally,

342 metabolism of D-arabinose [66] and allantoin [50] is associated with hyper-virulent Kp strains. As such,

343 metabolic flexibility may be a critical dictator of the variation in clinical outcomes for different *Klebsiella*

344 *spp*. or Kp pathogenic lineages. Our data, which support the above literature (Dataset S2, Fig S4),

345 suggests that this is indeed the case, as reduction of metabolic flexibility through deletion of *gltA*

346 drastically modifies fitness in different body sites (Figs 1, 6, S4). Subtle fine-tuning of metabolic capacity

347 may confer virulence or hypervirulence to a relatively avirulent Kp strain. Indeed, *gltA* has previously

348 been implicated to play a significant role in metabolic fine-tuning in the Lenski Experiment, wherein

349 mutation of *gltA* permitted access to a novel nutritional niche [68]. Further exploration of the

350 determinants of metabolic flexibility in Kp and the respective association with clinical outcomes is

351 necessary to fully understand how specific metabolic capacity influences fitness during infection.

352

353 While this study significantly advances our understanding of the role that metabolic flexibility plays in

354 determining fitness during infection, it is not without its limits. Firstly, this study does not address the

355 mechanism underlying the difference in amino acid content between the *Lcn2+/+* and *Lcn2-/-* lung.

356 Initially this result was unexpected; however, the effects of Lcn2 are not limited to antimicrobial activity.

357 Lcn2 has the ability to act as a growth and differentiation factor [69,70], as well as the ability to modulate

358 expression of many lung epithelial cell genes [25]. While the role of Lcn2 in these processes is not well

359 understood, it may be the case that deletion of *Lcn2* impacts lung homeostasis, leading to altered

360 physiology that explains the increase in amino acid levels. Although understanding the mechanism

361 underlying this phenotype is beyond the scope of this study, the phenotype served as a useful tool to

362 observe the effect of increased amino acid levels on Kp lung fitness. Secondly, this study exclusively

363 uses the Kp strain KPPR1. Thirdly, we have focused solely on the citrate (Si)-synthase GltA in

17

364 describing the role of metabolic flexibility during Kp infection and have not included any additional

365 metabolic enzymes. Additional studies including different strains of the *K. pneumoniae* complex and

366 focusing on additional metabolic pathways are necessary to fully understand the impact of metabolic

367 flexibility during infection.

368

369 In summary, we have described a novel role the Kp citrate synthase gene, *gltA*, as a critical mediator

370 of site-specific fitness during infection due to its influence on metabolic flexibility. Taken together, our

371 results represent an advancement in our understanding of Kp metabolism during infection and enhance

372 our knowledge of how these serious infections manifest, such that we are better able to combat these

373 dangerous bacteria.

374

Materials and Methods

Ethics statement

This study was performed in strict accordance with the recommendations in the *Guide for the Care and Use of Laboratory Animals* [71]. The University of Michigan Institutional Animal Care and Use Committee approved this research (PRO00007474).

Materials, media, and bacterial strains

All chemicals were purchased from Sigma-Aldrich (St. Louis, MO) unless otherwise indicated. *K. pneumoniae* KPPR1 [27], which is referred to as "KPPR1" throughout this study, and isogenic mutants were cultured in Luria-Bertani (LB, Becton, Dickinson and Company, Franklin Lakes, NJ) broth at 37°C with shaking, or in M9 minimal medium (M9 salts [Thermo Fisher Scientific, Waltham, MA], 0.2 M $MgSO_4$, 0.01 M $CaCl_2$, 20% glucose) at 37°C with shaking, or on LB agar at 30°C (Thermo Fisher Scientific). The isogenic *gltA* mutant was constructed as previously described [26,31]. Briefly, electrocompetent KPPR1 cells containing a modified pKD46 plasmid encoding a spectinomycin resistance cassette [26,31] were electroporated with a *gltA*-specific target site fragment containing a kanamycin resistance cassette isolated from the pKD4 plasmid [31]. Transformants were selected at 37°C on LB agar containing 25 µg/ml kanamycin, re-cultured, and confirmed by colony PCR using flanking primers (Table S1). The *gltA* complement plasmid was constructed using a Gibson Assembly Cloning Kit (New England Biolabs, Ipswich, MA). Briefly, the *gltA* sequence including its promoter was amplified from WT KPPR1 by PCR (Table S1) and ligated into the pACYC184 backbone [72] to create the pGltA plasmid. The ligation mixture was transformed into NEB 10-beta Competent *E. coli* (New England Biolabs) by heat shock. Transformants were selected at 37°C on LB agar containing 30 µg/ml chloramphenicol, re-cultured, and confirmed by colony PCR using (Table S1). Singe transformants were then grown in batch culture for plasmid extraction using the Plasmid Midi Kit (Qiagen, Germantown, MD). KPPR1Δ*gltA* competent cells were prepared as previously described [26],

19

electroporated with the pGltA plasmid, and selected at 37°C on LB agar containing 30 μg/ml chloramphenicol. Following selection, transformants were re-cultured, and confirmed by colony PCR (Table S1) and by growth in M9 minimal broth.

Transposon library construction and InSeq

Construction of the transposon library used in this study has been extensively described elsewhere [26]. Briefly, the pSAM_Ec plasmid [73] was modified by replacement of the ampicillin resistance cassette with a chloramphenicol acetyltransferase gene from the pKD3 plasmid [31] to create the pSAM_Cam plasmid [26]. The transposon library was constructed by mating KPPR1 with *E. coli* S17 λpir carrying the pSAM_Cam plasmid, followed by induction of the transposase by growth in the presence of 250 μM IPTG (Invitrogen, Carlsbad, CA) and selection on LB agar containing 25 μg/ml kanamycin and 30 μg/ml rifampicin. Insertion sequencing was performed as previously described [26] and deposited in the Sequence Read Archive (accession number to follow). KPPR1 has 5191 predicted genes [27], and previous calculations indicate that an inoculum of 1.1×10^5 CFU should result in a 99% probability of each transposon mutant being present at least once during lung infection [26]. Following infection, total recovered transposon mutants were collected, gDNA was isolated using the DNeasy Blood and Tissue Kit (Qiagen, Germantown, MD), and genomic sequences adjacent to insertion sites were amplified by PCR. Following amplification, Illumina sequencing adapters were ligated to amplified junction DNA fragments, and then fragments were sequencing on an Illumina HiSeq2500 Instrument (Illumina, San Diego, CA). Sequencing reads were filtered, mapped and normalized as described [26].

Murine models of infection

Six- to 12-week-old C57BL/6J mice (*Lcn2+/+*, Jackson Laboratory, Jackson, ME) or isogenic *Lcn2-/-* mice [28] were used for all murine models of infection. Kp was cultured overnight in LB, then bacteria were pelleted, resuspended, and diluted in sterile phosphate-buffered saline (PBS) to the appropriate

425 dose. For lung infection studies, a dose of $1×10^6$ CFU was determined to provide sufficient

426 representation of all mutants in the transposon library [26]. At the time of inoculation, mice were

427 anesthetized with isoflurane, approximately $1×10^6$ CFU was inoculated in the pharynx, and the mouse

428 was monitored until ambulatory. For validation of InSeq findings, WT KPPR1 and KPPR1$\Delta gltA$ were

429 cultured overnight in LB, then bacteria were pelleted, resuspended, mixed 1:1, diluted in sterile PBS to

430 the appropriate dose, and $1×10^6$ CFU was inoculated in the pharynx. After 24 hours, mice were

431 euthanized by CO_2 asphyxiation and lungs were collected, weighed, and homogenized in sterile PBS,

432 and homogenates were dilution plated on selective media to determine bacterial load. For bacteremia

433 studies, WT KPPR1 and KPPR1$\Delta gltA$ were cultured overnight in LB, then bacteria were pelleted,

434 resuspended, mixed 1:1, diluted in sterile PBS to the appropriate dose, and mice were inoculated

435 intraperitoneally with approximately $5×10^5$ CFU. After 24 hours, mice were euthanized by

436 CO_2 asphyxiation and blood, spleen, liver, and lungs were collected. Solid organs weighed and

437 homogenized in sterile PBS, and whole blood and solid organ homogenates were plated on selective

438 media. For oral inoculation studies, WT KPPR1 and KPPR1$\Delta gltA$ were cultured overnight in LB, then

439 bacteria were pelleted, resuspended, mixed 1:1, diluted in sterile PBS to the appropriate dose, and

440 mice were inoculated orally with approximately $5×10^6$ CFU. After 48 hours, mice were euthanized by

441 CO_2 asphyxiation and cecal contents were collected, weighed, and homogenized in sterile PBS, and

442 homogenates were dilution plated on selective media to determine bacterial load. In all models, mice

443 were monitored daily for signs of distress (hunched posture, ruffled fur, decreased mobility, and

444 dehydration) and euthanized at predetermined timepoints, or if signs of significant distress were

445 displayed. No blinding was performed between experimental groups.

446

Preparation of recombinant human lipocalin 2 protein and Lcn2 growth assay

448 Human lipocalin 2 was recombinantly expressed, purified, and validated as previously described

449 [46,74,75]. WT KPPR1 and various isogenic mutants were grown overnight in LB, then inoculated in

RPMI with 10% (v/v) heat-inactivated resting human serum with or without 1.6 μM purified recombinant human Lcn2 at a concentration of 1×10^3 CFU/mL. Cultures were incubated overnight at 37°C with 5% CO_2, and bacterial density was enumerated by dilution plating.

BioLog Phenotype MicroArray analysis

BioLog Phenotype MicroArrays (Biolog, Hayward, CA) analysis was performed in accordance with manufacturer's instruction with some modifications. WT KPPR1 and KPPR1Δ*gltA* were cultured overnight in LB, then bacteria were pelleted, washed once in sterile PBS, then re-suspended in sterile PBS. Each strain was diluted in IF-0 medium to a final OD_{600} of 0.035, then diluted again to final inoculation concentrations as per manufacturer's instruction. The final inoculum (100 μL) was plated onto plates PM1, PM2, and PM3. Sodium pyruvate (Thermo Fisher Scientific) was used as a carbon source for PM3 at a final concentration of 2 mM in accordance with previous metabolic phenotype analysis [66]. After inoculation, plates were sealed to avoid cross contamination of volatile compounds produced during Kp growth [66,76] and statically incubated overnight at 37°C. Following overnight incubation, growth was measured at OD_{595}.

Growth curves

The WT KPPR1 and KPPR1Δ*gltA* strains were cultured overnight in LB broth, then diluted to a uniform OD_{600} of 0.01 in the culture medium of interest the following day. Culture media included LB, M9 minimal medium with or without amino acid, carbon source, or serum supplementation, RPMI with 10% (v/v) serum (see "Preparation of recombinant human lipocalin 2 protein and Lcn2 growth assay" for details), and BALF (see below for details). Amino acids were supplemented at 10 mM unless otherwise indicated, and carbon sources were supplemented at 5 mg/mL. Cultures were incubated at 37°C and OD_{600} readings were taken every 15 min using an Eon microplate reader with Gen5 software (Version 2.0, BioTek, Winooski, VT) for up to 24 hours.

475

Serum growth assay

The WT KPPR1 and KPPR1Δ*gltA* strains were cultured overnight in LB broth with antibiotic supplementation, if necessary. Bacteria were then washed with M9 minimal media by centrifugation, resuspended, and diluted to an OD_{600} of 0.01 in M9 minimal media supplemented with 20% (v/v) murine or discarded human serum. For some experiments, sera were heat-inactivated at 56 °C for 30 minutes. Cultures were grown at 37°C and OD_{600} readings were taken every 15 min using an Eon microplate reader with Gen5 software (Version 2.0, BioTek, Winooski, VT) for up to 24 hours.

483

BALF growth assay

Six- to 12-week-old C57BL/6J mice (*Lcn2+/+*, Jackson Laboratory, Jackson, ME) or isogenic *Lcn2-/-* mice [28] were used for BALF collection. Briefly, mice were euthanized by CO_2 asphyxiation and tracheas were exposed. A small incision was made in the trachea, and polyethylene tubing (external diameter 0.965 mm, internal diameter 0.58 mm, BD, Franklin Lakes, NJ) attached to a 23-gauge luer-stub adaptor and syringe containing 2 mL sterile PBS. Following tubing insertion, 4-0 silk suture (Ethicon, Somerville, NJ) was used secure the trachea and then the lungs were flushed with PBS. BALF was kept on ice until processing, wherein BALF was centrifuged at 21,130 x *g* for 30 min at 4°C to pellet contaminating bacteria, then supernatant was stored at -80°C. Rifampin was added to BALF to a final concentration of 30 µg/ml immediately prior to use. The WT KPPR1 and KPPR1Δ*gltA* strains were cultured overnight in LB broth with antibiotic supplementation, if necessary. Bacteria were washed with PBS by centrifugation, resuspended, diluted to an OD_{600} of 0.1 in sterile PBS, then mixed with BALF from independent mice at a ratio of 1:9. Cultures were incubated at 37°C and OD_{600} readings were taken every 15 min using an Eon microplate reader with Gen5 software (Version 2.0, BioTek, Winooski, VT) for up to 24 hours.

499

500

Metabolomic analysis of BALF

For metabolomic analysis 100 μL of BALF was used. 20 μL was set aside to create a pooled sample from all study samples, and the remaining 80 μL of each BALF sample was prepared for GC-MS analysis according to manufacturer instructions using the Phenomenex EZFaast Free Amino Acids Analysis GC-MS kit (Phenomenex, Torrance, CA, USA). Briefly, BALF samples were combined with an internal standard (norvaline) and subjected to cation exchange solid phase extraction to purify amino acids from proteins, salts and other matrix components. The amino acids were then derivatized using a proprietary reagent and catalyst, the solvent is evaporated under a gentle nitrogen stream at room temperature, and finally the sample is resuspended for GC analysis. Quality control samples were prepared by pooling equal volumes of each sample and were injected at the beginning and the end of each analysis and after every 10 sample injections to provide a measurement of the system's stability and performance as well as reproducibility of the sample preparation method. The pooled sample was treated identically to the study samples and was analyzed along with the samples for quality control purposes. Calibration standards were prepared containing all 20 proteinogenic amino acids at concentrations of 10, 25, 50 and 100 μM and were analyzed in replicate along with samples to enable absolute quantitation of amino acids.

GC-MS analysis was performed on an Agilent 69890N GC -5975 MS detector with the following parameters: a 1 μL sample was injected with a 1:15 split ratio on an ZB-AAA 10 m column (Phenomenex, Torrance, CA, USA) with a He gas flow rate of 1.1 mL/min. The GC oven initial temperature was 110°C and was increased at 30°C per minute to 320°C. The inlet temperature was 250°C and the MS-source and quad temperatures were 230° and 150°C respectively. GC-MS data were processed using MassHunter Quantitative Analysis software version B.07.00. Amino acids were quantitated as μM/L BALF using linear calibration curves generated from the standards listed above.

24

525 To generate these curves, all peak areas in samples and calibration standards were first normalized to

526 the peak area of the internal standard, norvaline. Based on replicate analysis of biological samples,

527 the quantitative variability for all reported amino acids using this method is <15% RSD.

528

Statistical analysis

530 All *in vitro* experimental replicates represent biological replicates. For *in vitro* studies, except

531 metabolomic analysis, two-tailed Student's *t*-tests or ANOVA followed by Sidak's multiple comparisons

532 post-hoc test was used to determine significant differences between groups. For metabolomic analysis,

533 R version 3.5 and the "gplots," "pca3d," and "rgl" packages were used for data visualization and the

534 "limma" was package was used for false discovery rate correction. All animal studies except the InSeq

535 study were replicated at least twice. Competitive indices were log transformed and a one-sample *t*-test

536 was used to determine significant differences from a hypothetical value of 0 or two-tailed Student's *t*-

537 test was used to determine significant differences between groups. A *P* value of less than 0.05 was

538 considered statistically significant for the above experiments, and analysis was performed using Prism

539 6 (GraphPad Software, La Jolla, CA). For InSeq analysis, a p-value was first calculated for each

540 insertion using an exact Poisson test for comparing the two groups, and then the insertion-level p-

541 values were combined using Fisher's method [77] to obtain the statistical significance for each gene.

542 Finally, the p-values were adjusted to control the false discovery rate (Dabney A and Storey JD. qvalue:

543 Q-value estimation for false discovery rate control. R package version 1.43.0.). A *P* value of less than

544 1.3×10^{-5} was considered statistically significant.

Figure Legends

Fig 1. The Kp citrate synthase, *gltA*, interacts indirectly with Lcn2 during lung infection.

(A) A Lambda Red recombinase mutant of *gltA* (VK055_1802) was constructed and used to validate InSeq findings. C57BL/6J mice or isogenic *Lcn2-/-* mice were retropharyngeally inoculated with approximately 1×10^6 CFU of a 1:1 mix of WT KPPR1 and KPPR1Δ*gltA*. Lung bacterial burden was measured after 24 hours, and log competitive index of the mutant strain compared to the WT strain was calculated for each mouse strain (n = 10, mean displayed, *$P < 0.05$, ***$P < 0.0005$, ****$P < 0.00005$, one-sample *t* test or Student's *t* test). (B) WT KPPR1 and various isogenic mutants were grown in RPMI + 10% (v/v) heat-inactivated resting human serum ± purified recombinant human Lcn2 overnight, then total CFU was enumerated by dilution plating on selective media (n = 3-4, mean displayed ± SEM, ****P < 0.00005, Student's *t* test).

Fig 2. Deletion of *gltA* leads to diminished metabolic flexibility and distinct amino acid auxotrophy.

(A) Heatmap summarizing BioLog Phenotype Microarray analysis of WT KPPR1 and KPPR1Δ*gltA* growth in in 288 carbon and nitrogen limited growth conditions indicates multiple conditions that sustained growth of WT KPPR1 but not KPPR1Δ*gltA*. (B) A subset of growth conditions summarizing glycolysis and non-essential amino acid biosynthesis that indicates a distinct amino acid auxotrophy is induced by deletion of *gltA*. Arrows from citric acid cycle intermediates indicate amino acids that utilize these intermediates for biosynthesis. (C) A subset of growth conditions summarizing dipeptide utilization that further indicates induction of a distinct amino acid auxotrophy by deletion of *gltA* (n = 3, mean displayed, *$P < 0.05$, Student's *t* test).

Fig 3. Auxotrophy due to deletion of *gltA* is functionally complimented by glutamate.

774 (A) WT KPPR1, KPPR1Δ*gltA*, and KPPR1Δ*gltA*pGltA were grown in M9 minimal media + 20% glucose

775 with 10 mM glutamate (n = 3, mean displayed ± SEM) or (B) increasing concentrations of glutamate (n

776 = 3, mean displayed ± SEM). "+AA" label indicates addition of amino acid to growth media at

777 concentrations indicated in graph title.

778

779 **Fig 4. Bronchoalveolar lavage fluid from *Lcn2-/-* mice can sustain growth of KPPR1Δ*gltA* due to**

780 **increased amino acid levels.**

781 (A) Murine bronchoalveolar lavage fluid (BALF) was obtained from uninfected C57BL/6J mice or

782 isogenic *Lcn2-/-* mice, and WT KPPR1 and KPPR1Δ*gltA* were grown 100% BALF (n = 3, mean

783 displayed ± SEM). (B) Area under curve (AUC) analysis was used to compare growth of WT KPPR1

784 and KPPR1Δ*gltA* in *Lcn2+/+* and *Lcn2-/-* BALF. Data are normalized to growth of WT KPPR1 in *Lcn2+/+*

785 BALF (n = 3, mean displayed ± SEM, **$P < 0.005$, ANOVA followed by Sidak's multiple comparisons

786 post-hoc test). (C) Total amino acid content from uninfected C57BL/6J mice or isogenic *Lcn2-/-* mice

787 subjected to metabolomic analysis (n = 6-7, mean displayed, *$P < 0.05$, Student's *t* test). (D) Heatmap

788 of amino acid concentrations in BALF obtained from uninfected C57BL/6J mice or isogenic *Lcn2-/-* mice

789 subjected to metabolomic analysis (significantly different [FDR $P < 0.05$] amino acid concentrations

790 displayed, n ≥ 6 mice/group). Blue histogram in inset indicates composite amino acid concentration

791 values in heatmap matrix.

792

793 **Fig 5. *gltA* is dispensable for growth in human serum.**

794 (A) WT KPPR1 and KPPR1Δ*gltA* were grown in M9 minimal media + 20% resting human serum (n =

795 3, mean displayed ± SEM). (B) WT KPPR1, KPPR1Δ*gltA*, and KPPR1Δ*gltA*pGltA were grown M9

796 minimal media + 20% glucose with physiological levels of amino acids present in human serum (n = 3,

797 mean displayed ± SEM). "+AA" label indicates addition of amino acids to growth media at

798 concentrations indicated in graph title.

799

Fig 6. *gltA* influences compartmentalized fitness during bacteremia.

(A) C57BL/6J mice or isogenic *Lcn2-/-* mice were intraperitoneally inoculated with approximately 5×10^5 CFU of a 1:1 mix of WT KPPR1 and KPPR1Δ*gltA*. Bacterial burden in the blood, spleen, liver, and lung was measured after 24 hours, and log competitive index of the mutant strain compared to the WT strain was calculated for each mouse strain (n = 9-11/group, mean displayed, *$P < 0.05$, ****$P < 0.00005$, one-sample *t* test or Student's *t* test). (B) C57BL/6J mice or isogenic *Lcn2-/-* mice were orally inoculated with approximately 5×10^6 CFU of a 1:1 mix of WT KPPR1 and KPPR1Δ*gltA*. After 48 hours, mice were euthanized and cecal bacterial load was measured by dilution plating (n = 12-17, mean displayed, *P < 0.05, Student's *t* test).
