22 **Abstract**

23 Drought is the most perilous abiotic stress that affects finger millet growth and
24 productivity worldwide. For the successful production of finger millet, selection of
25 drought tolerant varieties is necessary and critical stages under drought stress,
26 germination and early seedling growth, ought to be fully understood. This study
27 investigated the physiological and biochemical responses of six finger millet varieties
28 (GBK043137, GBK043128, GBK043124, GBK043122, GBK043094 and
29 GBK043050) under mannitol-induced drought stress. Seeds were germinated on
30 sterile soil and irrigated with various concentrations of mannitol (200, 400 and 600
31 mM) for two weeks. Comparative analysis in terms of relative water content (RWC),
32 chlorophyll, proline, and malondialdehyde (MDA) contents were measured the
33 physiological and biochemical characteristics of drought stress. The results showed
34 that increased level of drought stress seriously decreased germination and early
35 seedling growth of finger millet varieties. However, root growth was increased. In
36 addition, exposition to drought stress triggered a significant decrease in relative water
37 content and chlorophyll content reduction the biochemical parameters assay showed
38 less reduction of relative water content. Furthermore, oxidative damage indicating
39 parameters such as proline concentration and MDA content increased. Varieties
40 GBK043137 and GBK043094 were less affected by drought as shown by significant
41 change in the physiological parameters. Our findings reveal the difference and linkage
42 between the physiological responses of finger millet to drought and are vital for
43 breeding and selection of drought tolerant varieties of finger millet. Further
44 investigations on genomic and molecular to deeply insight the detail mechanisms of
45 drought tolerance in finger millet need to explored.

50

51 **Introduction**

52 Drought stress, which mostly characterize arid and semi-arid regions of the world, is
53 one of the most severe environmental stress which is responsible for poor agricultural
54 productivity and yield decline (Zougmore, 2018). The climate of most of sub-Saharan
55 African is characterized by high temperature and low rainfall, during the vegetation
56 seasons. (Rishmaw et al., 2016). Due to global climate change, it is predicted that
57 drought episodes will increase in frequency, be longer and more severe, exacerbating
58 its negative effects on crops and compromise food security particularly in developing
59 countries. Over time, plants have evolved a range of drought tolerance adaptative
60 mechanisms to counteract the detrimental effects of drought. When grown under
61 desiccation stress, plants exhibit a sequence series of morphological, physiological,
62 biochemical, cellular and molecular changes that severely compromise plant's
63 growth, development and productivity (Li and Liu, 2016). Plants under water deficit
64 conditions decrease net photosynthesis and transpiration rates. These two
65 physiological responses, which vary depending on the species, are often seen in
66 regions with very high evaporative demand (Anjum et al., 2011). Protection systems
67 against excess reducing power are therefore a vital approach for plants under
68 desiccation stress (Chaves et al., 2009). Drought stress in plants is physiologically
69 complex and it encompasses osmotic stress and specific ion toxicity (Todaka et al.,
70 2015). Drought stress in plants is associated with nutritional imbalance, adjustment in
71 metabolic fluxes, distortion and disorganization of cell and chloroplast membranes as
72 well as reduction in division and expansion of cells and overproduction of reactive
73 oxygen species (ROS) (Forni et al., 2017). Toxicity accruing from overproduction of
74 ROS triggers cascades of oxidative reactions which consequently causes inactivation
75 of enzymes and increase of lipid peroxidation, whose final product is
76 malondialdehyde (MDA) and its quantification is used as a marker for oxidative
77 damage (Moller et al., 2007). To abate the effects of oxidative stress, plants have
78 evolved complex enzymatic and non-enzymatic systems. When exposed to water
79 deficit stress conditions, many plant species enhance the activities of antioxidant
80 enzyme which are associated with increased proline concentration (Ashraf and
81 Foolad, 2007). Proline plays significant role in the osmoregulation, allowing cells to
82 retain more water. Moreover, the amino acid also displays plant defense properties as

83 a ROS scavenger (Szabados and Saviouré, 2010) and as a regulator of the cellular
84 redox status (Sharma et al., 2011). Proline accumulation in plants is therefore
85 considered as a positive indicator for their tolerance to water stress (Verslues et al.,
86 2014). Plants capability to retain water during desiccation is a vital strategy for plant
87 tolerance to stress caused by water deficit stress. Accordingly, evaluation of relative
88 water content change is the best representation and a fast approach to evaluating
89 genetic differences in cellular hydration, plant water deficit and physiological water
90 status after water deficit stress treatments (Sánchez-Rodríguez et al. 2010). The best
91 effective approach of mitigating drought is the development of the tolerant crop
92 varieties. Accordingly, it is important to identify the genetic resources with high
93 tolerance and to understand the physiological and biochemical response mechanisms
94 of drought tolerance in important cereal crops such as finger millet.

95

96 Finger millet, [*Eleusine coracana* (L.) Gaertn.], is a cereal crop which is cultivated
97 semi-arid and arid regions of world under rain fed conditions (Thilakarathna &
98 Raizada, 2015). The crop plays a significant role in food security in arid and semi-arid
99 regions of sub-Saharan Africa and South Asia. Finger millet is therefore an ideal crop
100 for reshaping food propensity of people due to its nutritional richness, high
101 photosynthetic efficiency, and better tolerance to biotic and abiotic stresses than other
102 crops (Kumar et al., 2016). As a member of the *Panicoideae* subfamily, finger millet
103 acts as a model cereal crop for investigating basic biological processes. Although
104 most of the finger millet varieties are considered to be drought tolerant when
105 compared with other cereal crops, such as sorghum, maize, rice, barley and wheat, the
106 crop is drought sensitive especially at early stages, especially if the first rains of the
107 season are distant from each other. Genetic variations in response to drought stress
108 have been showed in many plant relatives and among accessions within the same
109 species. To our knowledge, there is no literature available which reports
110 morphological, physiological and biochemical responses of finger millet to water
111 deficit stress. We therefore investigated the physiological and biochemical
112 mechanisms involved in six finger millet varieties, from distinct geographical zones in
113 Kenya, under mannitol induced drought stress. Physiological and biochemical
114 parameters were measured such as germination rate, shoot growth and root growth,

115 relative water content (RWC), chlorophyll content, proline accumulation and lipid
116 peroxidation.

117

118 **Materials and methods**

119 **Plant material, growth conditions and germination assay**

120 Finger millet varieties GBK043137, GBK043128, GBK043124, GBK043122,
121 GBK043094 and GBK043050 obtained Kenya Agricultural and Livestock Research
122 Organization, Gene Bank, Muguga, Kenya were used in this study. Seeds were sorted
123 by handpicking of the healthy ones which were used for subsequent experiments.
124 Selected seeds were washed with distilled water to remove dust and other particles.
125 Germination assay was performed using 10 seeds of each variety. Seeds were planted
126 in germination trays containing sterile soil to a depth of approximately 1 cm and
127 irrigated with different concentrations of mannitol (200, 400 and 600 mM). The
128 controls were irrigated with distilled water. Drought stress on was imposed on
129 treatment groups by irrigating the seeds with various concentrations of mannitol at an
130 interval of 3 days for two weeks. Observations on the rate of germination were scored
131 on the 17th day of treatment.

132

133 **Growth conditions drought treatment**

134 Germinated finger millet seedlings were grown for 2 weeks under greenhouse
135 conditions of 25 ± 2 °C and 60-70% humidity, with a 16/8-h photoperiod provided by
136 natural sunlight. The seedlings were subjected to osmotic stress by irrigating with
137 mannitol (200, 400 and 600 mM) for 21 days at an interval of 3 days. Control plants
138 were watered with distilled water. Shoot length and root length were measured after
139 the experiment.

140

141 **Determination of relative water content**

142 A leaf was excised from each plant on the 21st day of water deficit stress.
143 Immediately, the fresh weight (FW) of each leaflet was determined. Thereafter, the
144 leaflet was immersed in double distilled water and incubated under normal room
145 temperature for 4 hours. Afterwards, the leaflet was taken out, thoroughly wiped to
146 remove the water on the blade surface and its weight measured to obtain turgid weight

147 (TW). the leaflet was afterwards dried in an oven for 24 hours and its dry weight
148 (DW) measured. The relative water content (RWC %) was calculated using the
149 formula: $RWC = [(FW - DW) / (TW - DW)] \times 100$.

150

151 **Total chlorophyll content**

152 Total chlorophyll (TC) content was determined using the method of described by
153 Arnon (1949). Fresh leaves (0.2 g) of leaves plants were crushed in 80% acetone. The
154 extract was centrifuged at 5000g for 3 minutes. The absorbance of the obtained
155 supernatants was measured at 645 and 663 nm using 1240 UV-Vis Spectrophotometer
156 (Shimadzu, Kyoto, Japan). The total chlorophyll content in each sample, expressed in
157 mg/g fresh mass (FM) was calculated using the formula: $TC = 20.2(A_{645}) +$
158 $8.02(A_{663}) \times V/1000 \times W$ where V corresponds to the volume of total extract per litre,
159 W is the mass of the fresh material and A is the absorbance as 645 and 663 nm.

160

161 **Estimation of proline content**

162 The amount of free proline in fresh plant leaves was determined as reported by Bates
163 et al. (1973). Fresh leaf tissues (50 mg) from each variety and treatment was
164 homogenized in 10 ml of 3% w/v sulphosalicylic acid and the homogenate filtrated.
165 The resulting solution was mixed with acidic ninhydrin solution [40% (w/v) acidic
166 ninhydrin (8.8 μ M ninhydrin, 10.5 M glacial acetic acid, 2.4 M orthophosphoric acid),
167 40% (v/v) glacial acetic acid and 20% (v/v) of 3%(v/v) sulphosalicylic acid].
168 Thereafter, the reaction mixtures were put in a water bath at 100 °C for 60 minutes to
169 develop colors. The reaction was terminated by incubating the mixtures in ice for 5
170 minutes. Toluene was added to separate chromophores. The optical density was
171 measured at 520 nm using 1240 UV-Vis Spectrophotometer. Free proline content
172 [μ mol/g fresh weight (F. WT)] in leaf tissues was calculated from a standard curve
173 made using 0-100 μ g L-proline.

174

175 **Lipid peroxidation assay**

176 Fresh upper second fully expended leaves (0.3 g) were harvested and homogenized in
177 0.1 % (w/v) trichloroacetic acid and the homogenates were centrifuged at 10,000 g for
178 15 minutes at 4 °C. The supernatant was mixed with 0.5 ml of 1.5 ml 0.5%

179 thiobarbituric acid diluted in 20% trichloroacetic acid and the resulting mixture was
180 heated to 95 °C for 25 minutes in water bath before incubating it on ice for 10
181 minutes. The absorbance was measured at 532 and 600 nm using UVmini-1240 UV-
182 Vis Spectrophotometer with 1% thiobarbituric acid in 20% trichloroacetic acid as
183 control. The amount of malondialdehyde ($\mu\text{mol/g FW}$) calculated as a measure of
184 lipid peroxidation, was determined according to Heath and Packer, (1968).

185

186 **Statistics data analysis**

187 The experiment was completely randomized block design with five replications of 10
188 plants. For germination and physiological assays, 10 seeds per replication were
189 employed. Data collected were subjected to one-way analysis of variance (ANOVA)
190 followed by a Fisher's protected LSD test to compare the means. A confidence level
191 was set at of 95% ($p \leq 0.05$). All statistical procedures were performed using Minitab
192 statistical computer software v.17.

193

194 **Results**

195 **Effects of drought stress on seed germination**

196 The results demonstrated that the gemination rate of the tested finger millet varieties
197 was significantly influenced by seed variety and mannitol concentration (Table 1).
198 Under untreated conditions, results showed that the highest gemination rate was
199 recorded after 5 days in variety GBK043137 (83.75%) followed by varieties
200 GBK043124, GBK043128, GBK043122 and GBK043050 whose gemination rates
201 ranged from 65.0% to 72.5%, while GBK043094 recorded the lowest one at 51.25%.
202 Seeds geminated in absence of stress treatment recorded superior gemination
203 percentages. Imposition of increasing concentration of mannitol resulted to a decrease
204 in germination percentage. The decline was significantly pronounced at 400 mM
205 mannitol where 0% germination rate for varieties GBK043137, GBK043122,
206 GBK043094 and GBK043050 were recorded while varieties GBK043124 and
207 GBK043128 recorded 16.25% and 1.25% germination rates respectively (Table 1).
208 Under moderate drought stress of 200 mM mannitol, variety GBK043137 recorded
209 the highest germination rate of 41.25% compared to the other varieties whose
210 germination rates ranged from 3.75% to 16.25% (Table 1). In severe osmotic pressure

211 of 600 mM mannitol concentration, none of planted seeds were germinated. The
212 average germination period under 0 mM mannitol concentration was 5.2 to 7.4 days
213 for all varieties, while under 200 mM mannitol the germination interval was longer,
214 ranging from 7.5 days to 13.6 days.

215

216 **Effects of drought stress on growth**

217 The present study investigated the changes in the growth parameters (shoot and root
218 growth) under mannitol induced drought conditions in all six finger millet varieties
219 selected. The plant growth in the six varieties recorded remarkably higher responses
220 in terms of shoot growth in absence of stress treatment compared to those exposed to
221 mannitol induced drought stress (Fig. 1). The shoot length decreased progressively
222 with increase in mannitol concentration (Table 2). Under mannitol stress conditions,
223 higher growth responses were recorded at 200 mM mannitol, while the least responses
224 were recorded at 600 mM mannitol (Table 2). Under stress conditions, variety
225 GBK043128 recorded highest shoot length (3.00 cm) while the least response was
226 observed in varieties GBK043137 and GBK043094 at 1.20 cm respectively (Table 2).
227 Significance differences on the effect of mannitol on shoot length were only observed
228 at 200 mM mannitol concentration. Higher mannitol concentrations did not record any
229 significance differences among the varieties on shoot length (Table 2).

230

231 Contrary to shoot growth under mannitol osmotic stress conditions, the six finger
232 millet varieties recorded an increase in root growth with increase in drought severity.
233 The mannitol stressed plants recorded relatively higher responses when compared to
234 control plants (Table 3). Variety GBK043094 recorded the highest root length under
235 drought of 6.00 cm at 600 mM mannitol while GBK043050 and GBK043137 showed
236 the least response with 2.30 cm and 2.60 cm respectively, at 200 mM mannitol
237 treatment level (Table 3). The observed increase of root length across different
238 drought stress levels was variety dependent.

239

240 **Effects of drought stress on relative water content**

241 Table 4 presents the RWC changes in finger millet leaves along with increase in
242 water-deficit stress. Under irrigated conditions, all varieties maintained the highest

243 RWC. Exposition of the plants to progressive mannitol concentrations simultaneously
244 reduced RWC values of all varieties. The per cent reduction in RWC was the highest
245 in GBK043122 which exhibited the lowest RWC value under water deficit stress at all
246 the mannitol regimes. Variety GBK043128 sustained relatively high values of RWC
247 and also showed lower percent reduction when compared to other varieties under
248 water deficit stress. Plants under moderate water stress treatment of 200 mM mannitol
249 displayed the highest diversity RWC values. The leaves exhibited wilting symptoms
250 and leaf rolling at severe drought stress treatments.

251

252 **Effects of drought stress on total chlorophyll content**

253 Results from our study show an inverse relationship between mannitol induced
254 drought stress responses and total chlorophyll content values for all finger millet
255 varieties. Differences for chlorophyll content values were also observed among
256 varieties. At the beginning of the experiment, total chlorophyll content across the
257 varieties was similar ranging from 15.35 to 21.74 mg/g FW (Table 5). Imposition of
258 moderate drought stress conditions of 200 mM mannitol caused a slight decrease of
259 chlorophyll content ranging from 5.08% for GBK043094 to 14.2% for variety
260 GBK043128. Significant decrease of ranging from 33.04 to 45.59% was observed at
261 severe water stress conditions of 600 mM. Among the varieties exposed to severe
262 water stress, varieties GBK043137 and GBK042094 retained relatively high
263 chlorophyll content while drought-sensitive varieties GBK043050, GBK043128,
264 GBK043122 and GBK043124 recorded a higher decline in chlorophyll reduction,
265 ranging from 42.4% to 45.59% under mannitol induced drought stress (Table 5). The
266 high drought-induced decrease of the total chlorophyll content signifies that drought
267 stresses induced a high loss of photosynthetic reaction centers.

268

269 **Effect of mannitol on proline content**

270 The variations among the varieties in proline content under control conditions were
271 significantly different and also did not follow any pattern (Table 6). In response to
272 drought stress, all the varieties exhibited a steep increase in leaf proline content and
273 the amount increased with the increased severity to the water stress. Variety
274 GBK042094 had highest proline accumulation while GBK043128 had the least

275 proline concentration in all mannitol treatments. Varietal differences in drought stress
276 induced proline were clearly observed in finger millet, signifying a correlation
277 between proline accumulation and differential mannitol induced water deficit stress
278 tolerance response among the six finger millet varieties studied.

279

280 **MDA content**

281 Lipid peroxidation was determined by measuring the accumulation of MDA, which is
282 natural product of oxidation of polyunsaturated fatty acids present in the membrane
283 caused by accumulation of peroxy radicals (Kotchoni, et al. 2006). Our results
284 revealed that the MDA levels in finger millet leaves was significantly influenced by
285 severity of mannitol induced osmotic stress and variety. At the beginning of the
286 experiment, no significant difference was registered in MDA values for all finger
287 millet varieties (Table 7). The MDA content was lower in control plants ranging from
288 2.1 to 2.79 $\mu\text{mol/g}$ FW compared to plants subjected to mannitol induced drought
289 stress which ranged from 2.77 to 7.23 $\mu\text{mol/g}$ FW. A progressive increase in the level
290 of lipid peroxidation was observed with concomitant increase of mannitol
291 concentration. The maximum MDA content under severe osmotic drought conditions
292 (600 mM mannitol) was observed in GBK043128 followed by GBK043050 and
293 GBK043122 varieties while varieties GBK042094 and GBK043137 had the least
294 MDA accumulation at similar conditions (Table 7).

295

296 **Discussion**

297 Drought stress induces different physiological, genetic and metabolic responses
298 among several species of plant and varieties. These responses are also influenced by
299 edaphic, climatic and agronomic factors (Caliz et al., 2015). Vulnerability of plants to
300 drought stress differentially varies in depending on stress severity, interactions among
301 stressors, plant species and stages of their development (Demirevska et al., 2009).
302 This natural allelic difference may provide valuable information into the mechanisms
303 which underline the differential responses to agriculturally important traits and search
304 of the crops that can survive such harsh environments may assist to ensure stable and
305 sustainable food production (Budak et al., 2013). As a dry-land crop, finger millet
306 growth and productivity is highly affected by drought stress which is projected to

307 increase in severity and frequency with current adverse climate change era. In order to
308 overcome this, there is need to develop new finger millet varieties with strong drought
309 tolerance traits as an effective way to achieve high and stable yields. For this to be
310 successful, precise identification of stress tolerance of finger millet varieties forms the
311 basis of developing resistant finger millet varieties. Therefore, dissecting the natural
312 differences of finger millet varieties could be viable to explore the complex
313 mechanisms of its response to various stresses. This study was done to investigate the
314 differential responses of finger millet to seed germination, growth, physiological and
315 biochemical responses after exposure to different concentrations of mannitol, which
316 causes osmotic stress and is commonly used as a drought simulator (Ullah et al.,
317 2014; Kaya et al., 2013; Karakas et al., 1997).

318

319 In plants life cycle, seed germination is the most critical and sensitive stage. The
320 process of seed gemination is constrained or even completely prevented by drought
321 stress (Hubbard et al. 2012). Germination potential is therefore an ideal index which
322 is used to assess the seed germination rate and germination uniformity. The
323 germination rate under simulated drought stress showed the tolerance, though the
324 responses were variety dependent. In absence of stress treatment, the six finger millet
325 varieties recorded better germination percentages. However, the rate declined with
326 increase in mannitol concentration treatment. Similar results have been reported in
327 other plant species such as maize (Liu et al. (2015), wheat (Yang et al., 2016) and
328 sunflower (Ahmad et al., 2009). Seed germination process is divided into three
329 successive stages: inhibition, metabolism that leads initiation of radicle growth, and
330 radicle growth which primes radicle emergence. A threshold level of hydration is
331 essential for the ensuing radicle elongation (Ramagopal, 1990). In normal seed
332 germination process, a threshold of the embryo hydration level needs to be attained,
333 which is a critical precondition for the successive initiation of cell elongation and
334 radicle development (Hegarty, 1978). In our study, the presence of mannitol could
335 have severely reduced internal osmotic potential of the germinating seeds, therefore
336 permitting the water uptake which subsequently leads to germination initiation
337 processes.

338

339 Plants capability to retain high water status during desiccation stress is a vital strategy
340 for plant tolerance to drought stress. Accordingly, evaluation of relative water content
341 change is the best representation and a fast approach to evaluating genetic differences
342 in cellular hydration, plant water deficit and physiological water status after water
343 deficit stress treatments (Sánchez-Rodríguez et al. 2010). Normally, high relative
344 water content values are treated as index of drought stress tolerance, as demonstrated
345 by Pandey et al. (2015) on rice genotypes tolerant or sensitive to drought. The
346 differences in relative water content in all varieties observed in our study could be
347 correlated with their different ability of water absorption from soil. The decline in
348 relative water content recorded was a main factor that caused decreased growth
349 responding to osmotic stress in the finger millet plants. Under desiccation stress,
350 sensitive finger millet varieties were more affected by the decrease in relative water
351 content than tolerant varieties. This suggested that the six finger millet varieties had
352 different sensitivity when subjected mannitol induced drought. The enhanced water
353 retention capacity observed in some of finger millet even when challenged by drought
354 could play a vital role in for plant survival under drought conditions water deficit.

355

356 Plants chlorophyll content heavily depends on the species physiological responses and
357 their ability to resist environmental stresses (Anjum et al., 2011). Evaluation of leaf
358 chlorophyll concentration is one of the most effective diagnostic tool for studies of
359 drought tolerance identification, genotypic variation, altitudinal variation and has
360 been employed in many crops including cereals such as sorghum (Qadir et al., 2015)
361 and foxtail millet (Wang et al., 2016). Plants can overcome this assault by increasing
362 the accumulation of chlorophyll which protects the plants by getting rid of excessive
363 energy by thermal dissipation (Reddy et al., 2004). Consequently, decline of
364 chlorophyll concentration in response to drought stress is a common phenomenon,
365 occasioned by disordering chlorophyll synthesis and resulting to plant chlorosis.
366 Additionally, when plants are subjected to environmental stresses, leaf chloroplasts
367 are injured which leads to disrupted photosynthesis. At higher mannitol
368 concentrations above 200 mM, chlorosis was observed in all the varieties, and the
369 leaves turned into pale yellow which lead to plant death.

370

371 Proline plays significant role in the osmoregulation, allowing cells to retain more
372 water. Moreover, the amino acid also displays plant defense properties as a ROS
373 scavenger (Szabados and Savouré, 2010) and as a regulator of the cellular redox status
374 (Sharma et al., 2011). Proline accumulation has therefore a positive connection with
375 their tolerance to various environmental stresses (Szabados and Savouré, 2010). In
376 our study, the mannitol stressed plants showed significantly higher proline
377 concentration was than control plants, especially in GBK042094. Our results revealed
378 that free proline accumulation in the leaf tissues of drought susceptible finger millet
379 varieties was significantly lower than the tolerant ones. These findings are
380 corroborated by the data reported in previous research work which indicate that total
381 free proline in the leaves are higher in water deficit tolerant than in drought
382 susceptible lines of maize (Efeoğlu et al., 2009), sweetpotato (Mbinda et al., 2018),
383 and rice (Pandey et al., 2015). The responses across the plant lines were
384 concomitantly increased with progressive increment of mannitol dosage. Our results
385 suggest that higher proline content in drought tolerant finger millet lines could be due
386 to altered expression of drought responsive genes which potentially improve the
387 hydration status of the plants. Our results also reinforce a close association between
388 increased proline concentration and plant relative water content in drought tolerance
389 mechanisms.

390

391 It is vital for antioxidative systems of plants to scavenge excess ROS in order to
392 maintain a balanced equilibrium of cellular reactions when they challenged stress
393 conditions (van Breusegem et al., 2018). The toxicity of ROS is due to their reactions
394 with numerous cell components, which cause lipid peroxidation among other cascades
395 of oxidative reactions (Wang et al., 2012). Cellular lipid peroxidation damages the
396 plasma membrane, leading to leakage of contents, swift desiccation and cellular death
397 (Demidchik, 2015). The final product of lipid peroxidation, is malondialdehyde and
398 this solute is one of the best physiological biomarkers of drought tolerance in plants
399 (Anjum et al., 2011). In this work, we found varieties and GBK043137 and
400 GBK043094 having the least amounts of MDA when challenged by drought stress
401 (Table 7). Low MDA levels has been correlated with desiccation stress tolerance and
402 the ensuing lipid peroxidation could induce the activity of antioxidant enzymes

403 (Wang et al., 2012). Accumulation of MDA when challenged by environmental
404 stresses has also been found to be a good drought tolerance index in other plant
405 species pitanga (Toscano et al., 2016), melon (Sarabi, et al., 2017), desi chickpea
406 (Farooq et al., 2018) and wheat (Mickky and Aldesuquy, 2016). From all the
407 physiological responses examined, it evident that of finger millet responses to drought
408 stress largely depends on the genotype/cultivars used the length and severity of water
409 deficit stress and the stage of development of the plant.

410

411 **Conclusion**

412 In conclusion, our study provided a broad analysis of the physiological features of
413 several finger millet plants to drought stress. The results reported here demonstrate
414 the impact of drought stress on the analysed parameters with a wide range of
415 variability among the studied varieties. Finger millet varieties GBK042094 and
416 GBK043137 could tolerate water deficit better than four the other varieties, as
417 indicated by significant decreases in germination rate, shoot length, root growth,
418 relative water content, leaf total chlorophyll content, proline accumulation and lipid
419 peroxidation. We deduced that these varieties are promising resources with
420 considerable level of tolerance to drought stress and they can be used for further
421 evaluations and breeding programs. Further investigations on genomic and molecular
422 to deeply insight the detail mechanisms of drought tolerance in finger millet need to
423 explored.

424

425 **Contributions**

426 AM and AN carried all the experiments. AM helped with draft the manuscript. CM,
427 RO, MM and WM supervised the study, contributed in statistical analysis and writing
428 the manuscript, WM conceived the idea, obtained of funding, contributed with
429 experimental design, coordination and manuscript writing. All authors agreed on the
430 final appearance of the manuscript after careful review.

431

432 **Acknowledgement**

433 This work was supported financially by a grant from The World Academy of Sciences
434 (Ref. No. 17-357 RG/BIO/AF/AC_I – FR3240297745) through the generous

435 contribution of the Swedish International Development Cooperation Agency. The
436 authors gratefully acknowledge Kenya Agricultural and Livestock Research
437 Organization, Gene Bank, for providing the finger millet seeds used. The authors also
438 thank the Department of Biochemistry and Biotechnology, Kenyatta University for
439 providing facilities for the research.

440

441 **Conflict of interests**

442 The authors declare that the study was conducted without of any commercial or
443 financial relationships that could be interpreted as a potential conflict of interest.

679 **Table 6. Effects of mannitol on proline content (µmol/g FW)**

Variety	0 mM	200 mM	400 mM	600 mM
GBK043137	1.76±0.09 ^a	2.12±0.19 ^{ab}	3.22±0.26 ^a	4.28±0.29 ^a
GBK043128	1.76±0.27 ^a	1.90±0.16 ^c	2.76±0.21 ^b	3.76±0.18 ^c
GBK043124	1.74±0.27 ^a	1.98±0.19 ^{abc}	2.84±0.17 ^b	3.50±0.14 ^c
GBK043122	1.86±0.34 ^a	1.92±0.23 ^{bc}	2.86±0.21 ^b	3.80±0.17 ^b
GBK042094	1.70±0.21 ^a	2.16±0.19 ^a	3.28±0.18 ^a	4.52±0.22 ^a
GBK043050	1.74±0.27 ^a	1.98±0.15 ^{abc}	2.82±0.19 ^b	3.60±0.24 ^{bc}

680 Means (±SE) followed by different alphabets in each column are significantly
 681 different (P≤0.05) using Fishers LSD.

682

683 **Table 7. Effects of mannitol on malondialdehyde content (µmol/g FW)**

Variety	0 mM	200 mM	400 mM	600 mM
GBK043137	2.03±0.55 ^c	2.77±0.39 ^c	4.29±0.62 ^d	5.26±0.34 ^c
GBK043128	2.27±0.46 ^{abc}	3.43±0.49 ^b	5.75±0.36 ^a	7.23±0.36 ^a
GBK043124	2.58±0.33 ^{abc}	3.91±0.37 ^{ab}	5.00±0.45 ^{bc}	6.17±0.47 ^b
GBK043122	2.66±0.38 ^{ab}	4.21±0.33 ^a	5.72±0.35 ^a	7.03±0.53 ^a
GBK042094	2.79±0.63 ^a	3.74±0.67 ^{ab}	4.41±0.77 ^{cd}	5.39±0.51 ^c
GBK043050	2.10±0.15 ^{bc}	3.63±0.27 ^b	5.67±0.60 ^{ab}	7.62±0.97 ^a

684 Means (±SE) followed by different alphabets in each column are significantly
 685 different (P≤0.05) using Fishers LSD.
