## Supplementary Notes

In all figures and tables, the $R$. mucronata populations are labeled as $\mathrm{m} 1, \mathrm{~m} 2, \mathrm{~m} 3, \mathrm{~m} 4, \mathrm{~m} 5, \mathrm{~m} 6$, and m 7 , while $R$. stylosa populations are labeled as $\mathrm{s} 1, \mathrm{~s} 2, \mathrm{~s} 3$, and s 4 , where " m " stands for $R$. mucronata and " s " stands for $R$. stylosa (Table S1). To refer to all the $R$. stylosa or $R$. mucronata populations, we use " Salll " or " $\mathrm{M}_{\text {all }}$ ". We use " $\mathrm{S}_{\text {allo" }}$ " to refer to the allopatric R. stylosa populations s2-s4 and " $\mathrm{M}_{\text {allo }}$ " to the allopatric $R$. mucronata populations $\mathrm{m} 2-\mathrm{m} 7$.

## Additional introgression tests between sympatric species

i) When comparing the two species, we identified 11,756 fixed SNPs and 759,472 shared SNPs (Table S5). Removing m1 and s1 (or DR samples), changes the SNP counts to 194,172 and 268,132 respectively. Removing allopatric populations does not affect the locus counts much, and the numbers remain around 12,000 and 720,000 (Table S5). This suggests that incomplete lineage sorting as not the cause of the observed admixture in the DR samples.
ii) We also observed an increased genome-wide linkage disequilibrium (LD) in m 1 and s 1 (Supplementary Fig. S5). Hence, if the background admixture in the allopatric populations reflects ancient polymorphism (or incomplete lineage sorting), the excess admixture we observed in m 1 and s 1 can be reasonably attributed to introgression private to m 1 and s 1 .
iii) We further used the ABBA-BABA (or $D$ ) statistic to test for the excess of shared derived alleles due to introgression ${ }^{76,77}$. A positive " $D$ " or " $f d$ " value is an indicator of introgression (gene flow). The tests with m 1 and s 1 as the subject branches all showed significant positive " $D$ " and " $f_{d}$ " values ( $\mathrm{P}<0.01$, Supplementary Table S 6 ). In contrast, no mean $D$ values significantly deviated from 0 ( $\mathrm{P}>0.5$ ) in the tests without ml or s 1 (Supplementary Table S6). Using 500kb sliding windows, we constructed distributions of $D$ values across the genome. Between $98.17 \%$ and $99.48 \%$ of the windows had positive $D$ values in the tests with ml and s 1 (Supplementary Fig. S6). In other words, introgression was only found between m 1 and s1 locally in Daintree River, where $R$. stylosa and $R$. mucronata are found together.

## Detecting highly differentiated amino acids between R. mucronata and R. stylosa

To find highly differentiated amino acids in the 30 candidate genes in j -blocks, we obtained protein sequences of all 52 individuals for each gene (Table 2 and Supplementary Table S10). We used the following criteria to call highly differentiated amino acids: 1) the differentiated nucleotide in the codon is a non-synonymous site and with $F_{S T}>0.8$ between $\mathrm{M}_{\text {allo }}$ and $\mathrm{S}_{\text {allo }}$ samples; 2) there are no identical homozygotes between $R$. mucronata and $R$. stylosa. We found 30 such amino acids between $R$. mucronata and $R$. stylosa in the 30 genes (Supplementary Table S10). Fourteen of these sites are located in the seven genes involved in flower development (Table 2 and Supplementary Fig. S12).

## The possible evolutionary trajectory and speciation of $R$. mucronata and R. stylosa

These observations re-enforce the notion that species characters vary over geographic range. Accepting that, we then ask what additional circumstances would be needed for speciation to occur and how might these conditions appear for the two Rhizophora species in this case study?

The characters shown for the two closely related species by these genetic and morphological studies have revealed distinct patterns and traits that appear to follow an ordered series of features tending towards genetic isolation and speciation. The order of events may have followed a scenario similar to the following ${ }^{37}$ :

1) It started with the dispersal of Asian R. mucronata into a vacant habitat as conditions became suitable in the west and south, but with concurrent selection favoring drift towards arid and marine traits to differentiate East African $R$. mucronata;
2) Propagules were transported by their exceptional ability for long distance dispersal and a specialized capability for establishment and growth in marine coastal conditions in a broad range of wet and dry climatic conditions;
3) These circumstances would have transported populations south and east towards Australia (in one or more founder events that selected a subset of genotypes which at some point became R._stylosa);
4) The longer style of R._stylosa further implies some possibly greater reliance on a particular pollinator, but this has not been established;
5) Ancestral Australian R._stylosa migrates further east and north along northern Australian shorelines, and then into SE Asia as well as the western Pacific where at some point it re-unites with ancestral Asian R._mucronata (still ecologically conditioned for upstream brackish estuarine locations);
6) Before this event, Asian R._mucronata populations would have been expanding east and south as conditions became more suitable across the region, but the proximity and size of populations would likely have prevented significant isolation events and no further speciation would have occurred.
7) The geomorphic circumstances of continental drift and their timing were likely critical in the progress of the biological events of dispersal and speciation ${ }^{79}$.

Removed populations: we removed two populations from all samples each time and then calculate the polymorphisms in the retained $R$. mucronata and R. stylosa. "none" means we kept all samples.

Table S6 Patterson's $D$ statistic and improved $f_{d}$ statistic, showing evidence of gene flow between $R$. mucronata (m1) and $R$. stylosa (s1) in sympatry in Daintree River, Australia

Table S10 All functional genes within non-introgressable blocks (j-blocks) between R. mucronata and R. stylosa

| In Rhizophora |  |  |  | In Arabidopsis thaliana |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Gene | j-sites | L(aa) | Mutant | Gene | Function |
| RA_05397 | 1 | 85 | 0 | AT4G31940 | Encodes a cytochrome P450 enzyme, CYP82C. It is involved in the early Fe deficiency response. Other names: CYP82C4. |
| RA_07374 | 2 | 145 | 0 | AT4G26370 | RNA binding domain of NusB (N protein-Utilization Substance B). The NusB protein plays a key role in the regulation of ribosomal RNA biosynthesis in eubacteria by modulating the efficiency of transcriptional antitermination. |
| RA_07376 | 2 | 172 | 0 | AT1G55490 | Encodes the beta subunit of the chloroplast chaperonin 60, a homologue of bacterial GroEL. Mutants in this gene develops lesions on its leaves, expresses systemic acquired resistance (SAR) and develops accelerated cell death to heat shock stress. Other names: CPN60B, CPN60BETA1, CPNB1, LEN1. This gene can participate in embryo and seed development ${ }^{8081}$. |
| RA_08385 | 2 | 286 | 1 | AT4G31050 | Biotin/lipoate $\mathrm{A} / \mathrm{B}$ protein ligase family. Involved in: protein modification process, lipoate biosynthetic process; Located in: cytoplasm. Other names: LIP2, OCTANOYL- TRANSFERASE. |
| RA_08689 | 2 | 259 | 2 | AT4G37280 | MRG family protein. Regulating flowering through elevating the expression of flowering genes FLC and FT (FLOWERING LOCUS C and T). The mutant shows a late-flowering phenotype. Involved in pollen germination, tube growth and cotyledon development. |
| RA_08699 | 1 | 452 | 1 | AT3G22990 | Armadillo-repeat containing protein. Other name: LEAF AND FLOWER RELATED, LFR. Required for all stages of pollen development. The expression is particularly strong in the tapetal cells and pollen grains. The null allele is male-sterile. |
| RA_08760 | 2 | 1105 | 2 | AT1G31690 |  |
| RA_08805 | 1 | 289 | 0 | AT3G06200 | P-loop containing nucleoside triphosphate hydrolases superfamily protein. Involved in chloroplast,cytosol phosphorylation, regulation of developmental growth. Located in chloroplast and cytosol. |
| RA_08848 | 2 | 560 | 2 | AT2G39090 | Tetratricopeptide repeat (TPR)-containing protein. Other names: APC7, ATAPC7. Involved in cell cycle, cell division,protein ubiquitination. Located in nucleus. |
| RA_10417 | 1 | 461 | 3 | AT4G32440 | Plant Tudor-like RNA-binding protein. Involved in biological progress. Located in nucleus. Participating in pollen germination and tube growth. |
| RA_11619 | 2 | 300 | 2 | AT5G17200 | Pectin lyase-like superfamily protein. Involved in carbohydrate metabolic process. Located in endomembrane system. Participating in early stage of female gametophyte development. |

| RA_13641 | 2 | 551 | 1 | AT3G56600 | Phosphatidylinositol 4-kinase gamma-like protein. Involved in phosphorylation. Expressed during: L mature pollen stage, M germinated pollen stage, 4 anthesis, petal differentiation and expansion stage. Expressed in flower tissues. Participating in pollen germination and tube growth. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| RA_15569 | 2 | 754 | 1 | AT1G08520 | Encodes the CHLD subunit of the Mg-chelatase enzyme. Involved in chlorophyll biosynthesis. Located in chloroplast and extracellular regions. Participating in embryo and seed development ${ }^{82}$. Lines carrying recessive mutations of this locus are white and seedling lethal. Other names: ALB-1V, ALB1, ALBINA 1, CHLD, PDE166, PIGMENT DEFECTIVE EMBRYO 166, V157. |
| RA_15894 | 2 | 560 | 0 | AT3G23310 | AGC (cAMP-dependent, cGMP-dependent and protein kinase C) kinase family protein. Involved in protein phosphorylation. Located in cytosol, nucleus and plasma membrane. |
| RA_16076 | 2 | 1162 | 3 | AT2G30070 | Encodes a high affinity potassium transporter. Involved in cell tip growth, potassium ion transmembrane transport and potassium ion transport. Located in membrane. Other name: ATKT1, ATKT1P, ATKUP1, KT1, KUP1, POTASSIUM TRANSPOTER1, POTASSIUM UPTAKE TRANSPOTER1. |
| $R A \_16163$ | 2 | 167 | 0 | AT5G52370 | 28S ribosomal S34 protein. Involved in biological process, response to cold. Located in chloroplast, mitochondrion. |
| RA_16173 | 2 | 407 | 2 | AT5G59380 | Protein containing methyl-CpG-binding domain. Has sequence similarity to human MBD proteins. The mRNA is cell-to-cell mobile. Other name:MBD6. |
| RA_16231 | 10 | 1028 | 0 | AT3G45850 | P-loop containing nucleoside triphosphate hydrolases superfamily protein. Function in: microtubule motor activity, ATP binding; Involved in: microtubule-based movement. |
| RA_16232 | 5 | 1399 | 1 | AT3G45830 | Nuclear factor kappa-B-binding-like protein. |
| RA_19120 | 3 | 1053 | 4 | AT1G09730 | Encodes a SUMO protease. Other names: ASP1, SPF1. Positively regulating the transition to flowering in long and short days. Along with SPF2, its activity is required for fertility as asp1/spf2 double mutants have defects in gametogenesis and embroygenesis. |
| RA_20369 | 2 | 367 | 1 | AT5G45950 | GDSL-motif esterase/acyltransferase/lipase. Expressed during flower, leave and plant embryo development stages. <br> Expressed in flower, leaf, plant embryo, hypocotyl and shoot tissues. Participating in pollen germination, tube growth, seed germination and floral development. |
| RA_20370 | 2 | 292 | 0 | AT5G45960 | GDSL-motif esterase/acyltransferase/lipase. Enzyme group with broad substrate specificity that may catalyze acyltransfer or hydrolase reactions with lipid and non-lipid substrates. Expressed during flower and plant embryo development. Expressed in flower, plant embryo, leaf and shoot tissues. |

| RA_20660 | 2 | 228 | 0 | unknown | Function unknown. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| RA_20751 | 1 | 453 | 0 | AT1G10020 | Formin-like protein (DUF1005). |
| RA_21335 | 2 | 620 | 1 | AT3G17000 | Group XIV ubiquitin-conjugating enzyme that functions negative regulation of drought stress. Other names: UBC32. |
| RA_22657 | 1 | 473 | 1 | AT3G55580 | Regulator of chromosome condensation (RCC1) family protein. Other names: TCF1, TOLERANT TO CHILLING AND FREEZING1. TCF1 encodes a member of the RCC1 gene family and is required for chromatin based gene regulation of cold responsive genes in a CBF-independent manner. It is expressed in response to cold but not ABA . |
| RA_23070 | 2 | 352 | 0 | AT1G29660 | GDSL-motif esterase/acyltransferase/lipase. Enzyme group with broad substrate specificity that may catalyze acyltransfer or hydrolase reactions with lipid and non-lipid substrates. Expressed during flower, leaf development and plant embryo globular stage. Expressed in flower, leaf, plant embryo, root, shoot and stem tissues. Participating in both early and late stages of female gametophyte development ${ }^{53}$. |
| RA_23103 | 1 | 136 | 0 | AT3G19900 | Hypothetical protein. |
| RA_23104 | 1 | 960 | 2 | AT3G22980 | Ribosomal protein S5/Elongation factor G/III/V family protein. |
| RA_24027 | 1 | 476 | 0 | AT5G63290 | Radical SAM superfamily protein. Function in oxidoreductase activity, iron-sulfur cluster binding, coproporphyrinogen oxidase activity, catalytic activity; Involved in oxidation reduction, porphyrin biosynthetic process. Located in chloroplast, cytoplasm. |

The seven bolded genes are involved in flower development (Table 2).
$j$-sites: the number of non-introgressable sites within the gene.
$L(a a)$ : amino acid sequence length of the gene.
${ }^{1}$ Site: No. of highly differentiated amino acids between $R$. mucronata and $R$. stylosa are given (see also Supplementary Fig. S12).

Table S11 Summary of non-introgressable blocks (j-blocks), including singleton blocks.

| No. of j-blocks (No. scaffolds with j-blocks) | $1,189(168)$ |
| :--- | :--- |
| Length of j-blocks - Range (mean) | $10 \mathrm{bp}-149.4 \mathrm{~Kb}(1,365 \mathrm{bp})$ |
| No. of j-sites in a block - Range (total non-i sites) | $1-7 \mathrm{bp}(1,398 \mathrm{bp})$ |
| Total length of j-blocks (\% of the genome) | $1,622,664 \mathrm{bp}(0.71 \%)$ |
| No. of genes within j-blocks | 395 |
| No. of genes containing j-sites | 263 |

A j-block has >= 1 non-introgressable sites ( j -sites).

## Supplementary Figures

Fig. S1. Phylogenetic relationships of $R$. mucronata and $R$. stylosa samples with (a) or without (b) sympatric populations ml and s 1 . Branches of $R$. mucronata populations (or individuals) are colored in orange while those of $R$. stylosa are in green. The Maximum Likelihood (ML) trees were generated by IQTREE ${ }^{39}$. Bootstrap values are provided on each branch.

Fig. S2. Phylogenetic relationships of $R$. mucronata and $R$. stylosa samples with (a) or without (b) sympatric populations ml and s1. Branches of $R$. mucronata populations (or individuals) are colored in orange while those of $R$. stylosa are in green. The Neighbor-joining (NJ) trees were generated by MEGA $7^{40}$. Bootstrap values are provided on each branch.

Fig. S3. PCA plot of all populations ${ }^{41}$. R. mucronata individuals are colored in orange while $R$. stylosa individuals in green. Allopatric populations ( $\mathrm{M}_{\text {allo }}$ and $\mathrm{S}_{\text {allo }}$ ) are highlighted by dotted lines.

Fig. S4. Cross-validation errors corresponding to different $K$ values in ADMIXTURE ${ }^{44}$. The best K is 2 with the lowest cross-validation score.

Fig. S5. Decay of linkage disequilibrium in $R$. mucronata and $R$. stylosa populations measured by $r^{2}$. Four groups: group1 contains population $m 6$ and $m 7$; group 2 includes population $m 2, m 3, m 4$, and m 5 ; group3 represents population s 2 and s 4 ; and group4 is population s 3 . The populations in the same group are genetically closely related to each other.

Fig. S6. Patterson's $D$ statistic scan across the genome for the genealogy models above, showing genome wide evidence of gene flow between sympatric populations ml and s 1 . The models colors correspond to the curves colors. In the last two genealogy models, $\mathrm{m}_{\mathbf{x}}$ represents $R$. mucronata population $\mathrm{m} 2, \mathrm{~m} 3, \mathrm{~m} 4, \mathrm{~m} 5, \mathrm{~m} 6$ or m 7 , and $\mathrm{s}_{\mathbf{x}}$ represents $R$. stylosa population $\mathrm{s} 2, \mathrm{~s} 3$ or s 4 (see Supplementary Table S7 for detail information).

Fig. S7. The site distributions in m 1 (orange) and s 1 (green) samples, classified by the occurrence of the i-allele (introgressed allele), which ranges from 0 to 10 (given five diploid individuals, or 10 genomes). The actual numbers of sites are shown. Sites in the orange (in m1) and green (in s1) solid boxes correspond to the site distributions in Fig. 3B. The orange and green dotted boxes contain the i-sites (with $>=8$ occurrences of i-allele) in m 1 and s1 populations, respectively. The black dotted box shows non-introgressable sites ( j -sites) with $<=1$ occurrences of i -allele both in m 1 and s1 samples.

Fig. S8. Examples of i-blocks (in blue dotted boxes) in ml genomes ( $\mathrm{a}, \mathrm{b}$, and c ) and in s 1 genomes ( $\mathrm{d}, \mathrm{e}$, and f ) at the site level. Only the d - and i -sites are displayed. Each site is color-coded for the MM, MS, and SS type (M for the R. mucronata variant and S for the $R$. stylosa variant, see Materials and Methods).

Fig. S9. The genome-wide landscape of i-blocks in m 1 and s 1 samples. All 52 . mucronata and $R$. stylosa individuals are shown. In each ideogram, all d- and i-sites are displayed consecutively. Each site is color-coded for the MM, MS, and SS types as in Fig. S10.

Fig. S10. GO (gene ontology) enrichment analysis of all genes in the j-blocks (or non-introgressable blocks) in Table S11, using WEGO 2.0 (Web Gene Ontology Annotation Plot, http://wego.genomics.org.cn/ $)^{83}$.

Fig. S11. Simulated introgressions in haploid 100 Kb genomes. Speciation genes are marked by red stars at the bottom. Sites of introgression and non-introgression are marked blue and pink, respectively. (A) Simulated results of 10000 generations under strong selection ( $s=-0.05$ ), low recombination rate ( $r=0.1$ for per 100 Kb per generation), and low introgression ( $1 / 1000$ per generation). Native alleles are not purified at non-selected sites. (B) Simulated results of 10000 generations under weak selection ( $s=-0.01$ ), low recombination rate ( $r=0.1$ for per 100 Kb per generation), and low introgression ( $1 / 1000$ per generation). Selected sites have introgressions, too. (C) Simulated results of 10000 generations under strong selection $(s=-0.05)+$ four loci under selection (\#41, \#51, \#71 and \#76), low recombination rate ( $\mathrm{r}=0.1$ for per 100 Kb per generation), and high introgression (10/1000 per generation). Selected sites have introgressions as well. (D-F) Simulated results under strong selection ( $\mathrm{s}=-0.05$ ), high recombination ( $\mathrm{r}=1.0$ for per 100 Kb per generation), and low introgression (1/1000 per generation). Three time points are given. This is closest to the expected pattern.

Fig. S12. Highly differentiated amino acids between R. mucronata and R. stylosa samples in the seven genes involved in flower development. Sites marked by red stars are fixed between allopatric R. mucronata (m2-m7) and R. stylosa (s2-s4) samples, and the rest each has 1-4 (number in red) heterozygotes in s 3 ( $R$. stylosa) population. Each site is color-coded for the M type (orange), Heterozygote (light green), and S type (green) (M for allopatric R. mucronata dominant amino acid and S for allopatric $R$. stylosa dominant amino acid).

[^0]:    ${ }^{\mathbf{i}}$ Effective sites: the sites that have at least one individual mapped (depth $>=2$ ) for each population.
    ${ }^{\text {ii }}$ Coverage rate: the ratio of effective sites and reference genome size. The reference ( $R$. apiculata) genome size equals to $232,430,847 \mathrm{bp}$.

[^1]:    ${ }^{\mathrm{i}}$ Effective sites: all sites that have at least two reads mapped (depth>=2) in each site.
    ${ }^{\text {ii }}$ Coverage rate: the ratio of effective sites and reference genome size. The reference genome size equals to 232430847 bps .
    ${ }^{\text {iii }}$ Mean depth: the average number of reads mapped at those sites.
    ${ }^{\text {iv }}$ Mean genome-wide heterozygosity (Ht) : the proportion occupied by heterozygotes of the genome.

[^2]:    ${ }^{\mathrm{i}}$ Effective sites: all sites that have at least two reads mapped (depth>=2) in each site.
    ${ }^{\text {ii }}$ Coverage rate: the ratio of effective sites and reference genome size. The reference genome size equals to 232430847 bps .
    ${ }^{\text {iii }}$ Mean depth: the average number of reads mapped at those sites.
    ${ }^{\text {iv }}$ Mean genome-wide heterozygosity $(\mathrm{Ht})$ : the proportion occupied by heterozygotes of the genome.

[^3]:    ${ }^{\text {a }}:$ code of $D$ statistic models. Models 1-11 exclude sympatric populations m 1 and s1; models 12-20 contain sympatric populations ml and s 1 .
    ${ }^{\mathrm{b}}$ : Pop1, Pop2, Pop3 and Outgroup respectively refer to the three ingroups and outgroup (ra: R. apiculata) followed the genealogical relationship (((Pop1, Pop2), Pop3), Outgroup).
    ${ }^{\text {c }}$ : result of $D$ statistic, given as a ratio $D \pm$ standard error.
    ***: the genome-wide average $D$-statistic value $D$ is significantly derived from 0 with $\mathrm{P}<0.01$, indicating the existence of gene flow between m 1 and s 1 populations.
    ${ }^{\text {d }}$ : result of $f_{d}$ statistic, given as a admixed proportion $f_{d} \pm$ standard error.
