Abstract

Water intake is regulated by neocortical top-down circuits, but their identity and the cellular mechanisms involved are scantily known. Here, we show that endogenous activation of type-1 cannabinoid receptors (CB₁) promotes water intake and that endocannabinoid modulation of excitatory projections from the anterior cingulate cortex to the basolateral amygdala is sufficient to guarantee physiological drinking. These data reveal a new circuit involved in the homeostatic control of water intake.

Water intake is crucial for maintaining body fluid homeostasis and animals' survival¹. Complex brain processes trigger thirst and drinking behavior, which arise upon losing blood volume (i.e. extracellular dehydration) or increasing blood osmolality (i.e. intracellular dehydration)¹. However, the central mechanisms promoting water intake are still poorly understood. In the brain, the anterior wall of the third ventricle formed by the subfornical organ (SFO), the median preoptic nucleus, and the organum vasculosum of the lamina terminalis (OVLT) constitutes the primary structure sensing thirst signals and promoting water intake^{2,3}. These subcortical regions are connected with the neocortex¹. In particular, insular and anterior cingulate cortices (IC and ACC, respectively) have been shown to receive indirect projections from the SFO and OVLT in rats⁴, and water consumption after dehydration decreases ACC activity in humans⁵. Furthermore, recent evidence shows that stimulation of the anterior part of IC promotes drinking behavior, whereas stimulation of the posterior part exerts the opposite effect⁶. These studies highlight the importance of cortical regions in the regulation of water intake^{1,4-6}.

Type-1 cannabinoid receptors (CB₁) are widely and abundantly expressed in the central nervous system where they modulate a variety of functions, including feeding behavior⁷⁻⁹. However, the role of CB₁ receptors in the control of water intake is still a matter of debate, since pharmacological activation or blockade of CB₁ receptors produced contradictory results in drinking behavior experiments^{10,11}. In this study, we identified a novel and specific cortical circuit where CB₁ receptors modulate water intake.

To examine the role of CB₁ receptors in the control of water intake, we first tested CB₁ knockout mice (CB₁-KO)¹² under different experimental conditions. No significant difference was observed between CB₁ wild-type (CB₁-WT) and CB₁-KO littermates in daily water intake (**Supplementary Fig. 1a**). However, CB₁-KO mice drank less than WT littermates after 24-hour water deprivation (**Fig. 1a, Supplementary Fig. 1b**), without any change in food intake (**Supplementary Fig. 1c**), indicating that CB₁ receptors participate in water deprivation-induced drinking behavior. Water deprivation triggers both intracellular and extracellular dehydration that can lead to water intake through different pathways¹. To discriminate the impact of CB₁ receptor signaling on either of these mechanisms, we first applied systemic (intraperitoneal, IP) or intracerebroventricular (ICV) injections of sodium chloride (NaCl), which are known to induce water intake by mimicking intracellular dehydration¹. As compared to wild-type littermates, mice lacking CB₁ receptors displayed a lower water intake induced by both IP or ICV NaCl administration (**Fig. 1b, c, Supplementary Fig. 1d**). Extracellular dehydration promotes the production of angiotensin II (ANG), which can induce drinking behavior and salt appetite¹. Thus, to mimic this condition, mice received ICV injections of ANG. Notably, the ANG-induced water intake was blunted in CB₁-KO mice (**Fig. 1d**), indicating that endocannabinoid signaling controls drinking behavior induced by both intracellular and extracellular dehydration mechanisms. Importantly, the acute systemic pharmacological blockade of CB₁ receptors decreased drinking under water deprivation and NaCl injections (**Fig. 1e, f**), indicating that endocannabinoid signaling is required at the moment of drinking and that the

phenotype of CB_1 -KO mice is not due to the long-lasting deletion of the gene¹³. Concomitantly with the abundant brain expression, CB_1 receptors are also present in peripheral organs⁷, suggesting that peripheral control of body water levels or blood osmolality might underlie the endocannabinoid-dependent regulation of water intake. However, measurements of body water composition and blood osmolality did not reveal any difference between CB_1 -KO mice and CB_1 -WT littermates (**Supplementary Fig. 1e, f**). Altogether, these results indicate that endogenous activation of CB_1 receptors contributes to drinking behavior induced by both intracellular and extracellular dehydration conditions, likely through central mechanisms.

CB_1 receptors are expressed in many different brain regions and in distinct cell types^{7,8,13}. To identify the specific cell-type involved in CB_1 receptor-dependent control of water intake, we used conditional mutant mice carrying deletion of the CB_1 gene in specific cell types, such as cortical glutamatergic neurons (Glu- CB_1 -KO)^{14,15}, forebrain GABAergic neurons (GABA- CB_1 -KO)^{14,15}, glial fibrillary acidic protein-positive cells (mainly astrocytes, GFAP- CB_1 -KO)^{14,16} and dopamine receptor D₁-positive cells (D₁- CB_1 -KO)^{14,17}. All these cell types have been implicated in the control of water intake¹⁻³. Surprisingly, however, none of these mutant lines displayed significant phenotypes in drinking behavior induced by water deprivation or NaCl injections (**Supplementary Fig. 2a-h**).

It is particularly puzzling how global, but not cell type-specific, CB_1 deletion can impact water intake. This may be due to the redundancy of CB_1 receptor-dependent

pathways controlling a function as vital as water intake. In this context, despite the general necessary role of the endocannabinoid system in controlling drinking behavior, this redundancy would decrease the specific *necessity* of selected subpopulations of CB₁ receptors. This, however, does not exclude that CB₁ receptor-dependent control of specific cell populations might play *sufficient* roles in controlling stimulated water intake. To address this possibility, we adopted a rescue approach and we used mice carrying specific and exclusive re-expression of the CB₁ protein in specific cell types (Stop-CB₁ mice approach)^{18,19}. A “floxed-stop” cassette prevents the expression of CB₁ receptors in the stop-CB₁ mutant line, similarly as in global CB₁-KO mice. Viral or transgenic expression of the Cre recombinase, however, induces the re-expression of the CB₁ receptors in particular brain regions and/or cell types over a “knockout-like” background^{18,19}.

First, we verified that Stop-CB₁ mice displayed the same impaired water intake as CB₁-KO mice and that global re-expression of the CB₁ protein is able to fully rescue water intake under deprivation and NaCl injections (CB₁-RS for CB₁ “rescued”; **Fig. 1g,h**)^{18,19}. Re-expression of CB₁ protein in GABAergic neurons (GABA-CB₁-RS mice)¹⁸, which include the large majority of brain CB₁ receptors^{7,8,13}, did not rescue drinking behavior either after water deprivation or IP NaCl injection (**Supplementary Fig. 2i, j**). Interestingly, however, re-expression of CB₁ receptors in cortical glutamatergic neurons (Glu-CB₁-RS)¹⁹, which represents a minority of the receptor in the brain^{7,8,13}, significantly rescued water intake induced by water deprivation, by systemic or central injection of NaCl, or by ICV ANG administration (**Fig. 1i-l**). These

data indicate that the presence of CB₁ receptors in cortical glutamatergic neurons is sufficient to promote water intake induced by different conditions.

Amongst other neocortical areas, the insular cortex (IC) has been directly shown to regulate water intake⁶. Therefore, we tested whether specific re-expression of CB₁ receptors in this brain region might rescue the impairment of water intake observed in Stop-CB₁ mice. Multiple local injections of an adeno-associated virus expressing Cre recombinase (AAV-Cre) into the IC of Stop-CB₁ mice resulted in a consistent CB₁ re-expression in both anterior and posterior portions of this brain region (IC-CB₁-RS; **Supplementary Fig. 3a-e**). However, this manipulation did not rescue the water intake associated with lack of CB₁ receptor protein (**Supplementary Fig. 3f,g**). Recent evidence points to the idea that the anterior and posterior parts of the IC play opposite roles in the control of drinking behavior⁶. In particular, activation of neurons located in the anterior IC (aIC) increases water intake, whereas the same manipulation of the posterior IC (pIC) exerts the opposite effect⁷. Considering that activation of CB₁ receptors generally reduces neuronal activity¹⁰, we reasoned that endocannabinoid control of the pIC leads to decreased neuronal activity and promotes drinking behavior. To test this possibility, we re-expressed the CB₁ protein exclusively in the pIC of Stop-CB₁ mice (pIC-CB₁-RS, **Supplementary Fig. 4a,b and 3e**), where the lack of the receptor should logically induce a reduction of drinking. However, also this partial re-expression did not rescue the phenotype of Stop-CB₁ mice (**Supplementary Fig. 4c,d**), strongly suggesting that CB₁ receptors in this brain region do not play a major role in water intake.

Recent studies suggest that the anterior cingulate cortex (ACC) might participate in the regulation of water intake^{1,4,5}. Using a similar approach as above, we generated ACC-*CB₁*-RS mice, in which the *CB₁* protein is re-expressed only in ACC principal neurons (**Fig. 2a-c**). Notably, ACC-*CB₁*-RS mice displayed significantly higher water intake than Stop-*CB₁* littermates (ACC-*CB₁*-SS) both after water deprivation and IP NaCl injection (**Fig. 2d,e**), indicating that the presence of *CB₁* receptors in principal neurons of the ACC is sufficient to promote drinking behavior induced by water deprivation and NaCl treatment.

As the ACC is a heterogeneous structure targeting multiple downstream regions, we next aimed at identifying which *CB₁*-positive projections from ACC are responsible for the stimulation of drinking behavior. First, we mapped the ACC neuronal projections interested by our local viral treatments. The injection of an AAV-CaMKII α -GFP virus into the ACC revealed that principal neurons of this neocortical region project to many brain areas, including the basolateral amygdala (BLA), the claustrum (Cl), the medial caudate putamen, the lateral habenula (**Supplementary Fig. 5 and video 1**). In order to analyze the expression of presynaptic *CB₁* receptors in these ACC projections, we evaluated the distribution of the *CB₁* protein in ACC-*CB₁*-RS mice. Interestingly, *CB₁* receptors were mainly present in the claustrum, the BLA, as well as in the ectorhinal and perirhinal cortices (**Fig. 2f-h, Supplementary video 2**). Recent evidence actually indicates that BLA is involved in the control of drinking behavior^{6,20}. We therefore asked whether *CB₁* receptors expressed in ACC to BLA projections (ACC-BLA) are sufficient to promote

water intake (**Fig. 3a**). To obtain selective rescue of the CB₁ protein in ACC-BLA terminals, we used a retrograde viral approach in the Stop-CB₁ mice. The injection of a retrograde AAV (rAAV2-retro) expressing flippases coupled to blue fluorescent protein (rAAV2-retro-FLIPo-EBFP) into the BLA of Stop-CB₁ mice was associated with the simultaneous infusion of another AAV carrying a FLIPo-dependent expression of Cre recombinase (AAV-FRT-iCre) into the ACC (**Fig. 3b**). These combinatorial viral manipulations resulted in a strong re-expression of CB₁ protein in ACC-BLA projecting neurons of Stop-CB₁ mice (ACC-BLA-CB₁-RS mice; **Fig. 3c-e**). Strikingly, after water deprivation and IP NaCl injection, ACC-BLA-CB₁-RS mice consumed significantly more water than control mice (**Fig. 3f,g**), revealing the key role of CB₁ receptor-dependent control of drinking in this specific brain circuit.

This study reveals an unforeseen circuit mechanism for top-down control of a fundamental life function such as water intake. Specifically, general CB₁ receptor activity is necessary to promote water intake, and its control of ACC principal neurons impinging onto BLA is sufficient to promote drinking behavior. These data highlight the complexity of brain control of water intake and underline the importance of top-down regulatory circuits in these processes.

Mice. All experiments were approved by the Committee on Animal Health and Care of INSERM and the French Ministry of Agriculture and Forestry. The authorizing number from the ethical committee is 15493. Maximal efforts were made to reduce the suffering and the number of used mice. All behavioral experiments were performed during the light phase and animals were kept in individual cages under standard conditions in a day/night cycle of 12/12 hours (lights on at 7 am). Male wild-type C57BL/6n mice purchased from Janvier (France) were used for the pharmacological experiments. All the used mutant mice were generated and identified in previous studies, e.g. global CB₁ knockout (CB₁-KO) mice¹², deletion of CB₁ receptors is specific in cortical glutamatergic Nex positive neurons (Glu-CB₁-KO)^{14,15}, forebrain GABAergic Dlx5/6 positive neurons (GABA-CB₁-KO)^{14,15}, astrocytes (GFAP-CB₁-KO)^{14,16}, and dopamine receptor type 1 positive neurons (D₁-CB₁-KO)^{14,17}. The stop-CB₁ mice^{18,19} (lack of CB₁), global re-expression of CB₁ receptors (CB₁-RS)^{18,19}, re-expression of CB₁ receptors is specific in forebrain GABAergic Dlx5/6 positive neurons (GABA-CB₁-RS)¹⁸ and cortical glutamatergic Nex

positive neurons (Glu-*CB₁*-RS)¹⁹. The mice used in this study were 7-10 weeks old at the beginning of the experiments.

Water intake assays. Water intake was observed at 30, 60 and 120 minutes after 24-hour water deprivation and intraperitoneal (IP) injection of 1M sodium chloride (NaCl, VWRV0241) with 10ml/kg body weight. In the pharmacological experiments, Rimonabant (3mg/kg, 9000484, Cayman Chemical Company US) and vehicle (4% ethanol, 4% Cremophor, 92% saline) were injected half an hour prior to the water intake test of the water deprivation or IP injection of 1.5 M NaCl with 10ml/kg body weight. For the mice of ICV injection, water intake was observed at 30 minutes after intracerebroventricular (ICV) injection of Angiotensin II (ANG, Bachem, H-1705.0025) and NaCl. We started to test water intake 7 days after the ICV cannula implantation. ICV injection was once a day in each mouse. In the progressive ANG dose-response experiments, we did ICV injections of saline, 5 ng, 15 ng, and 45 ng ANG (2µl/mouse) in different days. Then, we start the ICV NaCl injection 3 days after the last ICV ANG injection, ICV injection was once a day in each mouse. In the progressive NaCl dose-response experiments, we did ICV NaCl injections of 0.15M, 0.3M, 0.6M, and 1.2M NaCl (1µl/mouse) in the different days. In order to make sure that mice were drinking normally before the treatments, each mouse was observed the daily water intake during the experiments.

Body water composition analysis. The basal body water composition test was performed in mice by using a mouse-specific nuclear magnetic resonance whole body composition analyzer (EchoMRITM-900, EchoMedical Systems, Houston, TX).

Mice were placed in a specific chamber without strong movements, each readout was done within 1 minute. Mice were put back to home cages after the test.

Plasma osmolality analysis. Plasma osmolality was tested by Osmometer 3320 (Advanced Instruments, France). Facial vein blood collection was applied in this experiment. Blood was collected and put in the Micro tube 1.3 ml K3E (SARSTEDT, 41.1395.005), then blood samples were remained in room temperature for 30 minutes. By using a refrigerated centrifuge (VWR Micro Star 17R), blood samples were centrifuged with 4000 rpm for 15 minutes at 4°C. Following centrifugation, the plasma was immediately transferred to a clean eppendorf tube and put on the ice for the osmolality test.

Surgery and viral administration. Mice were anesthetized by isoflurane (5% induction, then, 2% during the surgery) and placed on a stereotaxic apparatus (Model 900, KOPF instruments, CA, USA) with a mouse adaptor and lateral ear bars. For viral vectors delivery, AAV vectors were loaded in a glass pipette and fused by a pump (UMP3-1, World Precision Instruments, FL, USA). AAV-GFP (Hybrid AAV1/2, 5 x 10E10 vg/ml), AAV-Cre-GFP (Hybrid AAV1/2, 4.5 x 10E10 vg/ml) were injected into the insula (IC) (200nl/side, 100nl/min). The coordinate of anterior IC injection is AP +1.2mm, ML $\pm$ 3.0mm, DV 3.5mm, and the coordinate of posterior IC injection is AP -0.3mm, ML $\pm$ 3.7mm, DV 4.0mm. AAV-CaMKII α -GFP (Hybrid AAV1/2, >1 x 10E10 vg/ml) or AAV-CaMKII α -Cre-HA (Hybrid AAV1/2, >1 x 10E10 vg/ml). The plasmids were provided by Karl Deisseroth, Stanford University, Stanford, CA) were injected into the anterior cingulate cortex (ACC) (200nl/side, 100nl/min). The coordinate of

ACC injection is AP +0.6mm, ML $\pm$ 0.3mm, DV 2.0mm, For the ACC-BLA-CB₁-RS or ACC-BLA-CB₁-SS mice, the AAV-FRT-iCre-GFP (Addgene #24593, ZNZ VVF v245, 6.3 x 10E12 vg/ml) was injected into ACC with the coordinates mentioned above in both group mice (200nl/side, 100nl/min). The rAAV2-retro-FLIPo-EBFP (Addgene #60663, ZNZ VVF v151, 6.4 x 10E12 vg/ml) or rAAV2-retro-EBFP (ZNZ VVF v140, 4.1 x 10E12 vg/ml) were injected into the BLA with the coordinates AP -1.6mm, ML $\pm$ 3.3mm, DV 4.9 mm (150nl/side, 100nl/min). AAV-FRT-iCre-GFP, rAAV2-retro-FLIPo-EBFP, and rAAV2-retro-EBFP were produced by the Viral Vector Facility (VVF) of the Neuroscience Center Zurich (ZNZ). The re-expression of CB₁ receptors was verified by the immunohistochemistry in all the mice used in the behavioral experiments. Above coordinates were according to the mouse brain in stereotaxic coordinates by Paxinos and Franklin, 2001 (Second edition).

Immunohistochemistry and imaging. After the behavioral experiment, mice were anesthetized with pentobarbital (Exagon, 400 mg/kg body weight), transcardially perfused first with the phosphate-buffered solution (PBS, 0.1M, pH 7.4), then fixed by 4% formaldehyde. After brain extraction, serial brain coronal sections were cut at 40 μ m and collected in PBS at room temperature (RT). Sections were permeabilized in a blocking solution of 4% donkey serum, 0.3% Triton X-100 and 0.02% sodium azide prepared in PBS for 1 hour at RT. For the CB₁ immunohistochemistry, free-floating sections were incubated with goat CB₁ receptors polyclonal primary antibodies (CB₁-Go-Af450-1; 1:2000, Frontier Science Co. ShinKO-nishi, Ishikari, Hokkaido, Japan) for 48 hours at 4°C. The antibody was prepared in the blocking solution. After

three washes, the sections were incubated with a secondary antibody anti-goat Alexa Fluor 555 (A21432, 1:500, Fisher Scientific) for 2 hours at RT and then washed in PBS at RT. For the HA immunohistochemistry, it is similar with the CB₁. Sections were incubated in anti-HA tag monoclonal antibody (1:1000, Fisher Scientific, 2-2.2.14) for 18 hours at 4°C and in secondary antibody anti-mouse Alexa Fluor 488 (A21202, 1:500, Fisher Scientific) for 2 hours at RT. All sections were mounted, dried and cover slipped. The sections were analyzed with a Nanoscope microscope (Hamamatsu, Japan) and Leica SP8 confocal microscope (Leica, Germany). Images were analyzed by Image J (NIH). For the mouse brain reconstruction, images were collected by Nanoscope, Z-stack images were made by Image J, and the 3D reconstruction and videos were made by Imaris software (Imaris, Oxford instrument, UK).

Statistics. Data handling and statistical analysis were performed using Microsoft Excel and GraphPad Prism 6 software. For the dose-response experiments of ICV NaCl and ICV ANG, and body water composition data were statistically analyzed by two-way analysis of variance (ANOVA). For the water intake test with several time points, data were statistically analyzed by the two-way repeated measures ANOVA. The data of IP NaCl dose response and plasma osmolality were statistically analyzed by two-tailed Student's t-test. P values of ≤ 0.05 were considered statistically significant at a confidence interval of 95%. For detailed statistical analysis, see statistical tables (Supplementary tables 1-2).

Supplementary Figure 1

Supplementary figure 1. Decrease of stimulated water intake in *CB₁*-KO mice is independent of food intake, body water composition, and plasma osmolality. **a**, Daily water intake of *CB₁*-WT (Black circles, n=9) and *CB₁*-KO (Open circles, n=8). **b**, Water intake in 24 hours after 24-hour water deprivation in *CB₁*-WT (White, n=10) and *CB₁*-KO (Gray, n=8) mice. **c**, Food intake in 24 hours after 24-hour water deprivation in *CB₁*-WT (White, n=10) and *CB₁*-KO (Gray, n=8) mice. **d**, Water intake in 1 hour after IP NaCl, 10ml/kg body weight at different doses in *CB₁*-WT (White, n=10) and *CB₁*-KO (Gray, n=8) mice. **e**, Body water composition test in *CB₁*-WT (White, n=8) and *CB₁*-KO (Gray, n=9) mice. **f**, Blood plasma osmolality test in *CB₁*-WT (White, n=8) and *CB₁*-KO (Gray, n=8) mice. All data are showed as mean $\pm$ s.e.m. Data of IP NaCl dose response and 24-hour water intake after water deprivation were statistically analyzed by two-tailed Student's t-test. * $P < 0.05$, ** $P < 0.01$.

Supplementary Figure 2

Supplementary figure 2. Deletion or re-expression of CB₁ receptors in specific cell

types did not affect water intake.

a-d, Cumulative water intake after 24-hour water deprivation in Glu-CB₁-WT (Black circles, n=18) and Glu-CB₁-KO (Open circles, n=11), GABA-CB₁-WT (Black circles, n=6) and GABA-CB₁-KO (Open circles, n=10), GFAP-CB₁-WT (Black circles, n=7) and GFAP-CB₁-KO (Open circles, n=11), D₁-CB₁-WT (Black circles, n=5) and D₁-CB₁-KO (Open circles, n=7). **e-h**, Cumulative water intake after IP 1M NaCl, 10ml/kg body weight in Glu-CB₁-WT (Black circles, n=18) and Glu-CB₁-KO (Open circles, n=11), GABA-CB₁-WT (Black circles, n=6) and GABA-CB₁-KO (Open circles, n=10), GFAP-CB₁-WT (Black circles, n=7) and GFAP-CB₁-KO (Open circles, n=11), D₁-CB₁-WT (Black circles, n=5) and D₁-CB₁-KO (Open circles, n=7). **i**, Cumulative water intake after 24-hour water deprivation in stop-CB₁ (Open squares, n=8) and GABA-CB₁-RS (Black squares, n=8). **j**, Cumulative water intake after IP NaCl, 10ml/kg body weight in stop-CB₁ (Open squares, n=10) and GABA-CB₁-RS (Black squares, n=8). All data are showed as mean ± s.e.m, and were statistically analyzed by the two-way repeated measurements ANOVA.
