21 **Abstract—50 words**

22 Historically described as a commensal of the swine upper-respiratory tract, *Streptococcus*
 23 *equi* subsp. *zooepidemicus* was only reported previously in Asia as an important swine pathogen.
 24 Here we report the isolation and whole genome characterization of *Streptococcus equi* subsp.
 25 *zooepidemicus* associated with a sudden death outbreak in pigs in North America.

26 **Text—764 words**

27 *Streptococcus equi* subsp. *zooepidemicus* (*S. zooepidemicus*) is considered a commensal
 28 and opportunistic pathogen of several warm-blooded hosts, including humans, horses, different
 29 canines and swine. It is a Gram-positive, β -hemolytic coccus belonging to the Lancefield group
 30 C. It can cause severe disease characterized by pneumonia, septicemia and meningitis (1, 2). *S.*
 31 *zooepidemicus* has been suggested as a normal inhabitant of the palatine tonsils of pigs, being
 32 detected by both culture and high-throughput sequencing in samples collected from healthy
 33 animals (3). However, strains virulent to pigs have also been reported in the literature,
 34 particularly associated with high-mortality outbreaks of sudden death and respiratory disease in
 35 China (4). Currently, there are no vaccines available for this pathogen and control and prevention
 36 methods are hardly applied, given its commensal nature in swine. Here, we report an outbreak of
 37 sudden death associated with *S. zooepidemicus* in pigs housed in intensive rearing, commercial
 38 facilities in North America.

39 In April 2019 an outbreak of sudden death and abortions occurred in 4 loose-housed,
 40 commercial sow farms (approximately 9000 sows) in a large vertically integrated swine system
 41 within the province of Manitoba. This outbreak increased the cumulative mortality in the 3

affected sows herds by more than 1000 sows in the following 12 weeks. The abortion rate during this time period was approximately 11 x the normal rate. Animals were often described as apparently healthy during morning checks. Over the course of hours, sows would become unwilling to stand, develop fever, lethargy and die with no other apparent clinical signs. Other sows would abort and then go on to develop similar symptoms. Stressing factors in these farms, such as mixing of animals and the presence of other sick animals appeared to exacerbate outbreaks within pens. Animals were fed a commercial grade, nutritionally balanced diet as per ESF (electronic sow feeding) and had access to water *ad libitum*. Gross *post-mortem* examination of multiple animals, either euthanized or recently deceased, revealed the following common observations: rhinitis (mucopurulent discharge, mild, diffuse), pulmonary edema, gall bladder edema, hemorrhagic lymphadenopathy (tan to haemorrhagic) consisting of submandibular, cervical neck and bronchial lymph nodes, which taken together are suggestive of sepsis. All animals tested negative for PRRSV, *Mycoplasma hyopneumoniae*, SIV-A, PCV-3 and PCV-2 by real-time PCR. In parallel, Gram positive cocci were observed in imprints from heart and submandibular lymph nodes. Aerobic bacterial culture followed by Matrix-Assisted Laser Desorption/Ionization-Time Of Flight (MALDI-TOF) for identification of isolates revealed varying levels of *S. zooepidemicus* in liver, kidney, heart, brain, lung, spleen, and submandibular lymphnodes. Isolate identification was confirmed by two different veterinary diagnostic laboratories. Isolates (n=7, SAMN13058951, SAMN13058952, SAMN13058953, SAMN13058954, SAMN13058955, SAMN13058956, SAMN13058957) were found resistant to lincomycin, neomycin and tetracycline and susceptible to ampicillin, ceftiofur, penicillin and tilmicosin in a Kirby-Bauer disk diffusion assay.

DNA extraction was performed from isolates (DNeasy Powersoil Pro kit, Qiagen), quantified by Nanodrop (3300) and PicoGreen (Quant-iT dsDNA) and processed for sequencing (Illumina Nextera XT library prep kit). Sequencing was performed using MiSeq Nano V2 (2x250 paired-end). Samples yield an average of 149,017 high quality reads, suggesting 50x coverage (genome size averaged 2.1 mbp). Genome assembly, annotation and downstream analyses were conducted using the PATRIC package (5). Genomes averaged 2.1 million bp in size, and 41.34% in GC content. All isolates were similar to previously published *S. zooepidemicus* genomes (Figure 1), demonstrating a whole-genome average nucleotide identity (ANIScore) of 99.7% to strain *S. zooepidemicus* ATCC35246. This particular strain was reported as isolated from a septicemic pig during an outbreak that killed over 300,000 pigs in Sichuan province, China, in 1976 (6). Interestingly, all isolates had an average ANIScore of 97.3%, when compared to *S. zooepidemicus* strain 4047, an isolate considered virulent, obtained from a horse diagnosed with strangles in the United Kingdom (7). In addition, all isolates obtained from pigs, regardless of what outbreak, were profiled as MLST (multi-locus sequence type) ST-194, including strain ATCC35246. Antimicrobial resistance genes identified in isolates from this outbreak included *gidB*, *S12p* (streptomycin), *rpoB* (rifampin), *S10p* (tetracycline), *kasA* (triclosan), *PgsA*, *LiaR*, *LiaS* (daptomycin), *folA*, *Dft* (trimethoprim), *folP* (sulfadiazine) and *FabK* (triclosan). Virulence factors found included the previously described *szm*, *lmb*, *fbpZ*, *skc*, *has* operon and *mag* regulon, which help explain the highly-virulent lifestyle of these isolates.

Taken together, these findings suggest the emergence of *S. zooepidemicus* ST-194 as a cause of mortality in pigs in North America. This specific sequence type seem to be particularly virulent to pigs, for reasons that remain unexplained. Given the clinical presentation described

here, this pathogen requires special attention and should no longer be overlooked, due to its historically accepted commensal lifestyle, when conducting diagnostic investigations.
