23 Abstract

24 Clonorchis sinensis-a fluke dwelling on the intrahepatic bile ducts causes
 25 clonorchiasis. During C. sinensis infection, worm-host interaction results in activation
 26 of PRRs and further triggers immune responses which determine the outcome of
 27 infection. However, the mechanisms by which pathogen-associated molecules
 28 patterns from C. sinensis interacted with TLRs were poorly understood. In the present
 29 study, we identified a ~34 kDa lipoprotein CsHscB from C. sinensis which physically
 30 bound with TLR2. We also found that recombinant CsHscB (rCsHscB) potently
 31 activated macrophage to express various proteins including TLR2, CD80, MHCII,
 32 and cytokines like IL-6, TNF- α , and IL-10 in a TLR2-dependent manner but rCsHscB
 33 failed to induce IL-10 in macrophages from *Tlr2*^{-/-} mice. Moreover, ERK1/2
 34 activation was required for rCsHscB-induced IL-10 production in macrophages. In
 35 vivo study revealed that rCsHscB triggered a high induction of IL-10 in the wild-type
 36 (WT) but not in *Tlr2*^{-/-} mice. Our data thus demonstrate that rCsHscB from C. sinensis
 37 is an unidentified TLR2 agonist with immune regulatory activities, and may have
 38 some therapeutic implications in future beyond parasitology.

46 **Introduction**

47

48 During helminth infection, the complex host-parasite interaction triggers host immune
 49 responses which ultimately drive the resistance to infection or immune evades
 50 accompanying with the course of immunopathogenesis. For this view, type 2 immune
 51 responses including IL-4, IL-9, IL-5 and IL-13 secreted by ILC2, Th2 or alternatively
 52 activated macrophage (AAM or M2) are typically considered as protective immunity
 53 against helminths to results in parasite expulsion ultimately [1]. However, the
 54 regulatory cells (Treg, Breg, ILCreg, M2c etc) can produce the regulatory cytokines
 55 (IL-10, etc) to ameliorate the bias of type II immune responses, which appears to be
 56 mainly responsible for the worms survival with the limited immunological damages
 57 and further establishment of chronic infection [2]. Further studies have demonstrated
 58 that MAPK (such as ERK, p38) and NF- κ B signaling (NF- κ B p50 homodimers)
 59 contribute to the mechanisms that control the production of IL-10 [3, 4]. However, the
 60 mechanisms by which the complex immune responses are initiated and
 61 finely-orchestrated remains poorly elucidated.

62 Toll-like receptors represent one of most important pattern recognition receptors
 63 (PRRs) that sense the conserved pathogen products (also called pathogen-associated
 64 molecular pattern, PAMP) from worms or alarming (also called dangers-associated
 65 molecular pattern, DAMP) sourced from damage tissues in the early event of
 66 infection. For example, TLR2 collaborated with TLR1 or TLR6 recognize triacylated

67 or diacylated lipoproteins, respectively and thereby activate signal transduction
68 cascades to result in the expression of pro-inflammatory or anti-inflammatory
69 mediator genes [5-7]. So far several TLR2 ligands from *S. mansoni*,
70 *Wolbachia*-endosymbiotic bacteria of *Brugia malayi* have been identified and
71 demonstrated as potent immune regulators to determine the polarization of immune
72 and even the outcome of helminth infection. For example, lysophosphatidylserine
73 (Lyso-PS) from *S. mansoni* bound with TLR2 on dendritic cells allows DC to train
74 IL-10 producing Tregs, which enables the long term survival of the parasite, as well as
75 ameliorates of immunopathogenesis due to polarized type 2 immune responses [8].
76 Diacyl WoLP sourced from *Wolbachia* induces dendritic cell maturation and
77 activation as well as drives CD4 T cell polarization and antibody switching in a
78 TLR2-dependent manner [9].

79 Clonorchiasis caused by *Clonorchis sinensis* remains a major parasitic disease in
80 eastern Asia such as China, Korea, Vietnam and eastern Russia [10]. There are
81 approximately 15 million people infected worldwide whereas 12.5 million people are
82 distributed in China, posing a severe public health issue in these regions. The adult
83 worms dwelling on the intrahepatic bile duct cause cholelithiasis, cholangitis,
84 cholecystitis, biliary fibrosis and even cirrhosis due to its long-term survival.
85 Additionally, chronic infection with this fluke has been shown to cause
86 cholangiocarcinoma (CCA) and *C. sinensis* is now defined as Group 1 human
87 biological agents (carcinogens) by International Agency of Research on Cancer
88 (IARC) due to sufficient pieces of evidence in human [11, 12]. Previous studies have

89 shown that the components of *C. sinensis* excretory/secretory products (ESPs) and
90 crude antigen (CA) can potentially induce a type 2 or a mix type1/type2 immune
91 responses *in vitro* [13-15]. *In vivo* study, during *C. sinensis* infection, the interaction
92 between worms and host immune cells also potentially drives type I immune responses
93 with type 2 becoming more prevalent after worms are well-developed in susceptible
94 hosts [16]. Furthermore, our previous study also showed that the expression of TLR2
95 is dramatically changed with the prolonged infection, which suggested that TLR2
96 might be involved in this dramatically immunological changing [17]. However, the
97 mechanisms that account for this phenotypic shifting is poorly understood so far. In
98 view of this background, the objectives of the present study were to identify the
99 molecules from *C. sinensis* that are responsible for activation of TLR2 and investigate
100 its possible effects on the activation on macrophage. In our present study, we
101 identified a lipoprotein-rCsHscB interacted with TLR2 acting as an unidentified
102 TLR2 agonist induce the activation of macrophage secreting high levels of
103 pro-inflammatory and anti-inflammatory cytokines in a TLR2-dependent manner. Our
104 present study will contribute to a better understanding of the interaction between the
105 *C. sinensis* and host cells. In addition, in view of regulatory immune capacities of
106 rCsHscB, our study also provides an alternative therapeutic approach for implications
107 beyond parasitology.

108

109 **Materials and Methods**

110

111 **Ethics**

112 Animal care and all experimental perform in this study were conformed to the
113 guidelines of the National Laboratory Animal Center. The main procedures and
114 protocol were reviewed and approved by the Animal Care and Use Committee of
115 Xuzhou Medical University License (2016-SK-03).

116

117 **Mice**

118 Male C57BL/6 mice (specific pathogen-free, SPF) aged 8 weeks (20-22g) were
119 purchased from the Beijing Vital River Laboratory Animal Technology Co. Ltd. The
120 mice were group-housed in a specific pathogen-free condition with
121 temperature-control room (25 °C). All mice were given standard chow diet and tap
122 water *ad libitum*.

123 To obtain *C. sinensis*-positive sera, BALB/c mice were orally infected by 45
124 nangyou and the mice were sacrificed on 28 days and 56 day post-infection (p.i.), the
125 sera from *C. sinensis*-infected mice and no-infected mice were collected for further
126 use.

127 Mice were immunized with around 10 µg of *C. sinensis* crude antigen in IFA. Two
128 booster doses in IFA were injected in 15 days interval. Titers of antibody against to *C.*
129 *sinensis* crude antigen were determined by ELISA.

130

131 **Preparation of rCsHscB and control protein**

132 rCsHscB and control protein (only His-tagged protein encoded by pET-28a vector

without CsHscB open reading frame) were routinely expressed by *E. coli* (Ec).
rCsHscB was purified by nickel-affinity and ion-exchange chromatography. For more
details, see the Supplementary Material.

Development of specific rCsHscB polyclonal antibody

The Ab to the rCsHscB protein was generated in rabbits that were maintained in the
animal house facility of Xuzhou Medical University. In brief, rabbits were immunized
with around 10 µg of rCsHscB in IFA. Two booster doses in IFA were injected in 15
days interval. After measuring the rCsHscB-specific Ab titer by ELISA, animals were
sacrificed at day 45 to collect and separate sera. The poly-antibody against rCsHscB
was purified by metal affinity chromatography. In an immunoblot, the Ab raised
against the rCsHscB protein specifically recognized single band of ~36 kDa.

Immunohistochemistry

rCsHscB was stained on paraffin-embedded adult worm *C. sinensis* by
immunohistochemistry using the affinity-purified anti-rCsHscB antibody. Reactivity
was detected using Dako REAL™ EnVision™ Detection System ((Dako, Glostrup,
Denmark). Sections were counterstained with hematoxylin and photographed by a
microscope.

Cell culture and stimulation

Mouse mononuclear macrophage leukemia cells RAW264.7 with 5~10 passages were

155 cultured in DMEM (Hyclone, US) containing 10% fetal bovine serum (FBS) (Serana,
156 AUS), 1% penicillin/streptomycin (Beyotime, China) in a humidified atmosphere with
157 5% CO₂ at 37°C. RAW264.7 cells were stimulated by rCsHscB (5~20 µg/ml) for 6 h,
158 12 h and 24 h. Supernatants were collected for assessing the concentrations of
159 cytokines using ELISA. For TLR2 blocking assay, RAW 264.7 cells were pretreated
160 with MAb-mTLR2 (2 µg/ml) or isotype (Invivogen, US) for 2 h. The cells were then
161 stimulated by rCsHscB (20 µg/ml) or Pam₃CSK₄ (200 ng/ml) (Invivogen, US) for 24
162 h in a humidified atmosphere with 5% CO₂ at 37 °C. The supernatants and cultured
163 cells were collected for flow cytometry assays for ELISA, respectively.

164 Bone marrow cells were obtained from the long bones of 8- to 10-week-old C57BL/6
165 mice (WT or *Tlr2*^{-/-}). Bone marrow cells were cultured in the presence of M-CSF (20
166 ng/mL) (PeproTech, USA) for six days to generate the bone marrow-derived
167 macrophages (BMDMs). BMDMs were cultured in DMEM (Hyclone, US) containing
168 10% fetal bovine serum (FBS) (Serana, AUS), 1% penicillin/streptomycin (Beyotime,
169 China) in a humidified atmosphere with 5% CO₂ at 37°C. Thereafter, BMDMs were
170 stimulated by rCsHscB (5~40 µg/ml) or production of *E. coli* transfected by pET-28
171 control vectors for 24h and supernatants were obtained for determining the
172 concentration of IL-10 using ELISA. For ERK1/2 inhibitor assay, PD98059 (1 µM)
173 (Sigama, US) was pre-incubated with cells for 2 h, BMDMs from WT or *Tlr2*^{-/-} mice
174 were stimulated by rCsHscB (20 µg/ml) or Pam₃CSK₄ (200 ng/ml) (Invivogen, US)
175 and supernatants were used for ELISA.

176

177 **Western blotting analysis**

178 Total cell lysates or rCsHscB were separated by 10% SDS-polyacrylamide gel
179 electrophoresis (PAGE) and transferred onto Immobilon-P Transfer Membranes
180 (PVDF) (Millipore, USA). For detection specific antibodies against to rCsHscB in
181 vivo, sera from *C. sinensis*-infected and non-infected mice, as well as *C. sinensis*
182 crude antigens immunizing sera as primary antibodies for 12 h at 4°C, and then
183 horseradish peroxidase-conjugated secondary antibody (Beyotime, China) were
184 incubated. For detection of MAPK signaling, the PVDFs were blocked with 5%
185 non-fat-milk in PBS-Tween (PBS-T) and incubated with anti-His (ZSGB-Bio, China),
186 anti-phospho ERK (CST, US), anti-phospho p38 (CST, US), anti-TLR2 (CST, US),
187 anti-β-actin (Beyotime, China), and horseradish peroxidase-conjugated secondary
188 antibody (Beyotime, China). The PVDFs were visualized by ECL exposure to X-ray
189 film. Densitometry analyses were performed by Image Lab software.

190

191 **Flow cytometry**

192 Following stimulation, RAW264.7 were stained with TLR2 (eFlour 660), CD80 (PE),
193 CD86 (eFlour 450), major histocompatibility complex class II (FITC), CD206
194 (PE/Cy7), CD11b (APC-Cy7). BMDMs were stained with TLR2 (eFlour 660), CD11b
195 (APC-Cy7), F4/80 (Percp-Cy5.5). Antibodies were purchased from BD Pharmigen
196 (US). Samples were analyzed with FlowJo software.

197

198 **ELISA**

Supernatants from RAW264.7 or BMMs cultures were analyzed using commercially available ELISA kits for IL-10, IL-6 and TNF- α (all from eBioscience, San Diego, CA, US).

Pull-down assay

The cells were stimulated by supernatant of lysate from *E. Coli* transfecting with Vector controls (pET-28, His-tagged control), pET-28a-CsHscB vectors (pET-28-CsHscB, unpurified), purified rCsHscB-stimulated cells, binding buffer and medium for 24 h, subsequently, the cells from each group were lysed for further use. The rCsHscB were incubated with Ni-NTA beads (QIAGEN, GER) for 12h at 4°C after the agaroses were balanced with binding buffer at 4 times in 4°C. rCsHscB immobilized on bead were incubated with total cell lysates (RAW264.7) for 12h at 4°C. The supernatant was discarded after centrifuged at 2500 rpm for 5 minutes in 4°C. The bead-bound proteins were subjected to 10% SDS-PAGE and then transferred electrophoretically to PVDF membranes. The membranes were incubated with anti-His antibody or anti-TLR2 antibody, followed by horseradish peroxidase-conjugated secondary antibody (Beyotime, China). The PVDFs were visualized by ECL exposure to X-ray film.

Statistical analysis

All data were expressed as the mean $\pm$ standard error of the means (SEM). One-way ANOVA was used to analyze the significance of the differences between groups,

221 followed by Tukey's test using SPSS 13.0. For all tests, $P < 0.05$ was considered
222 statistically significant.

223

224 **Results and discussion**

225

226 **Identification, characterization and immunogenicity of recombinant *C. sinensis***

227 **HscB**

228 As most TLR2 agonists or ligands have been reported as lipoproteins or lipopeptides
229 [18], to identify potential agonist of TLR2 sourced from *C. sinensis*, we collected all
230 the amino acid sequences encoding *C. sinensis* proteins from the proteome data
231 (<http://www.ncbi.nlm.nih.gov/bioproject/PRJDA72781>) and then putative lipoproteins
232 from *C. sinensis* proteome were screened and predicted using a combination of
233 DOLOP, lipoP and Lipo database as previously described [9]. We ultimately identified
234 a lipoprotein named molecular chaperone HscB (CsHscB), which had 283 amino
235 acids with three domains as followed: DnaJ, Co-chaperone HscB (COHscB) and
236 C-terminal oligomerization (CTO) (Fig. 1A). Alignment of amino acid sequences
237 analysis showed that the sequences of *C. sinensis* HscB had more than 90%
238 similarities to *Opisthorchis viverrini* hypothetical protein (XP_009168973.1), but only
239 had 40.91% similarities to the putative co-chaperone protein HscB from *Schistosoma*
240 *mansoni* and 33.64% to the co-chaperone HscB from *Echinococcus granulosus* (Fig.
241 1B). The candidate lipoproteins were further selected for prediction of N-terminal
242 signal peptide using SignalIP server 3.0 (<http://www.cbs.dtu.dk/services/SignalP-3.0/>)

243 by a hidden Markov model (HMM) [19]. CsHscB had a signal peptide (the probability
244 was 0.759, Fig. 1C) and the predicted cleavage sites was at between N-terminal 34
245 and 35 sites (Fig.1C).

246 However, it was very difficult to isolate and purify CsHscB directly from the worms
247 due to lack of the sufficient background information as well as the low yield. We
248 therefore used a recombinant CsHscB (rCsHscB) that was routinely expressed by *E.*
249 *coli* (Ec). rCsHscB was purified by nickel-affinity and ion-exchange chromatography,
250 and the purified rCsHscB was assessed by western-blot (Fig 1D). The molecular
251 weight of rCsHscB including a 6×his tag was approximate 36 kDa (Fig 1D).

252 Furthermore, we prepared the specific rCsHscB antibody to examine the expression
253 and distribution of CsHscB in worm body using immunohistochemistry (IHC). IHC
254 data showed that CsHscB mainly expressed on the oral sucker (OS), genital pore (GP),
255 vitelline gland (VF), ovary (OV), testis (TT) and eggs (EG) (Fig. 1E). It could be
256 detected by the sera from *C. sinensis*-infected mice as well as *C. sinensis* crude
257 antigen- immunized mice, suggesting that rCsHscB was recognized by pool of
258 antibodies induced by *C. sinensis* and crude antigen as well. It is also suggested that
259 CsHscB naturally existing in *C. sinensis*- infection mice and worm's crude antigens
260 can trigger host immune responses (Fig. S 1).

261 **rCsHscB induces the activation of macrophage and cytokine production**

262 To test whether rCsHscB has the capacity to induce the activation of innate immune
263 cells or not, we used a macrophage cell line-RAW 264.7 that were stimulated by
264 various concentrations of rCsHscB at different time-points. Firstly, we test toxicity of

265 rCsHscB to macrophages, lactate dehydrogenase (LDH) test showed that up to 20 μg
266 /ml of rCsHscB protein displayed no cellular toxicity against macrophages (the data is
267 not shown). Furthermore, endotoxin (LPS) in the purified rCsHscB was removed by
268 Endotoxin Erasol Solution (Tiandz, Beijing, China) in order to exclude any potential
269 effects of LPS produced during preparation of rCsHscB. The concentration of
270 endotoxin was detected by Limulus Amebocyte Lysate (LAL) and rCsHscB solution
271 with less than 0.1 EU/ml of endotoxin should be further studied. For assessment of the
272 activation of macrophages, we detected activation markers of macrophages upon
273 stimulation using flow cytometry. The data showed that stimulation of macrophage
274 with rCsHscB (20 $\mu\text{g}/\text{ml}$) for 24 h augmented the surface expression of activation
275 markers such as TLR2, CD80, CD86, MHCII, CD206 and CD11b (Fig. 2A~F). We
276 also detected these cytokines with various concentrations (5~20 $\mu\text{g}/\text{ml}$) of rCsHscB at
277 different time courses, it was shown that macrophages stimulated by 5~20 $\mu\text{g}/\text{ml}$
278 rCsHscB for 12 h produced high levels of TNF- α (Fig. 2G). In addition, rCsHscB
279 with the concentration of 5~10 $\mu\text{g}/\text{ml}$ but not 20 $\mu\text{g}/\text{ml}$ for 24 h still induced a robust
280 secretion of TNF- α produced by macrophage (~3 times greater than
281 DMEM-stimulated cells, Fig. 2G). The cells also produced high levels of IL-6 under
282 the stimulation with 5~20 $\mu\text{g}/\text{ml}$ rCsHscB for 12 h or 24 h, compared with
283 medium-stimulated cells (Fig. 2H, $P<0.05$). With regard to IL-10, cells stimulated
284 with 5~20 $\mu\text{g}/\text{ml}$ rCsHscB for 12 h or 24 h could produce a robust increase of IL-10,
285 of note, the secretion of IL-10 in macrophage stimulated by 20 $\mu\text{g}/\text{ml}$ rCsHscB for 24
286 h was more than 10 times greater than that of DMEM-stimulated cells (Fig. 2I). We

also tested the levels of IL-4 and IL-12 produced by rCsHscB-stimulated macrophage, but the data showed that the macrophage stimulated by rCsHscB didn't increase the production of IL-4 and IL-12 (the data is not shown). To exclude any potential effects of endotoxin and other potential component produced during preparation of rCsHscB on the activation of macrophage, we also compared the productions of *E. Coli* induced by pET-28a vector with or without CsHscB open reading frame (pET-28a-CsHscB or control vector), the production induced by control vector could not stimulate macrophage to secrete high levels of IL-10 and TNF- α (Fig. S2A and Fig. S2B). However, it seems that the cells that were stimulated by the production expressed by control vector also secreted a higher level of IL-6, compared with DMEM stimulated cells, although the level of IL-6 was still lower than that of pET-28a-CsHscB-induced cells, suggesting that the increased secretion of IL-6 may be not exclusively induced by rCsHscB (Fig. S2C). Together, these data demonstrate that rCsHscB induces the activation of macrophage and triggers a robust cytokines production by the macrophage.

302

rCsHscB is an unidentified agonist for TLR2 to induce immune responses of macrophage

305

As the lipoproteins or lipopeptides have been reported as TLR2 agonist or ligand [18], we next test whether rCsHscB as an agonist for TLR2 to promote the activation of macrophage or not. Firstly, we performed *in silico* molecular docking using the crystal

structure of the extracellular domain (ECD) of mouse TLR2 and modeled 3D structure of rCsHscB by homology modeling. Molecular docking showed that CsHscB could bind with TLR2 at its leucine-rich region (LRR) 11~15 sites of ECD (Fig. 3A). To further ascertain whether rCsHscB physically interacts with the TLR2 molecule or not, we performed a pull-down assay using whole-cell extracts from RAW247.6 cells stimulated by rCsHscB. The cell extracts were incubated with rCsHscB immobilized on Ni-NTA beads. TLR2 Pull down assay revealed that supernatant of lysate from *E. Coli* transfecting with pET-28a-CsHscB vectors as well as purified rCsHscB proteins could pull-down TLR2 molecule as showed by western-blot (Fig. 3B line 2 and line 3), demonstrating that TLR2 and rCsHscB could be physically interacted. However, if rCsHscB (control vectors for example) absence, no bands were observed on the gel of western-blot, which suggested there is no interactions between TLR2 and other molecules except rCsHscB (Fig. 3B line 1 and line 4). Collectively, these data suggested that rCsHscB interacts specifically and predominantly with TLR2.

To test whether rCsHscB induced the cytokines production is dependent on TLR2 or not, TLR2 was blocked by pretreating RAW 264.7 cells with anti-TLR2 antibody (T2.5) for 2 h prior to the addition of rCsHscB. The secretion of IL-6 and IL-10 induced by rCsHscB were almost abrogated following the addition of TLR2 blocking antibodies to the medium (Fig. 3D and Fig. 3E). Similarly, rCsHscB-induced TNF- α was also significantly abolished due to the presence of the TLR2 blocking antibody (Fig. 3F).

331

332 **rCsHscB-induced IL-10 production partly depends on phosphorylation of**
 333 **ERK1/2 but not p38 in RAW 264.7 cells**

334 IL-10 has been known as one of the mechanisms that contribute to induced regulatory
 335 responses induced by helminth infection (30). As our and others' previous studies
 336 suggest that IL-10 might play a regulatory role in immune responses during *C.*
 337 *sinensis* infection[17, 20-22], which highlight the significance of rCsHscB induced a
 338 strong IL-10 production in macrophage in our study, it is necessary to further study
 339 the mechanisms that IL-10 induced by rCsHscB. For this sense, to determine which
 340 downstream molecules mediated by TLR2 are responsible to robust rCsHscB-induced
 341 IL-10 production by macrophage, we screened the activation of transcription factors
 342 nuclear factor- κ B (NF- κ B), p38 mitogen-activated protein kinase and ERK1/2 in
 343 RAW264.7 cells using optimal concentrations (20 μ g/ml) of rCsHscB during various
 344 time courses, western blot showed that rCsHscB induced a robust phosphorylation of
 345 ERK1/2 after 20~30 min and then the levels of phosphorylation of ERK1/2 was
 346 attenuated during 60 min~120 min following stimulation with rCsHscB (Fig. 4A).
 347 Surprisingly, there was no obviously activation of NF- κ B nor p38 during these time
 348 courses. Furthermore, we also examined whether the rCsHscB-induced
 349 phosphorylation of ERK1/2 was mediated by TLR2 signaling. RAW264.7 cells were
 350 pretreated with blocking antibodies of TLR2 or with isotype control and
 351 phosphorylation of ERK1/2 was measured by western blot. Western blot showed
 352 that phosphorylation of ERK1 but not ERK2 was solely abolished following the

addition of TLR2 blocking antibodies to the cultures, compared with isotype-matched control. Furthermore, we used a specific inhibitor for ERK1/2 (PD98059) to examine whether rCsHscB-induced cytokines was mediated by ERK signaling pathway or not. The RAW264.7 cells were pretreated with 10 μ M PD98059 for 2 h, and then stimulated by 20 μ g/ml rCsHscB for 24 h, the supernatants were collected for IL-10 detection. The data showed that the level of IL-10 was significantly decreased when ERK1/2 was inhibited by PD98059 in macrophage that was stimulated by rCsHscB for 24 h (Fig. 4C, $P < 0.001$, ~50% decreased).

361

rCsHscB-induced IL-10 production depends on TLR2-mediated ERK1/2 signaling in bone marrow-derived macrophage

364

To ascertain the roles of TLR2-regulated ERK1/2 signaling in rCsHscB-induced IL-10 in macrophage, we induced bone marrow-derived macrophage (BMDM) from *Tlr2* wild type and *Tlr2*^{-/-} mice. Similar to our previous data, rCsHscB could potentially induced a strong TLR2 expression on the surface of BMDM sourced from wild type mice (Fig. 5A, almost 2 fold changes) and the levels of IL-10 were significantly increased when BMDM cells from *Tlr2* wild-type mice were stimulated at various concentration of rCsHscB (5~40 μ g/ml), compared with medium or the production of *E. coli* transfected by empty vector (Fig. 5B, $P < 0.001$). Furthermore, the production of IL-10 reached peak at the concentration of 20 μ g/ml (almost 6 times increase). However, rCsHscB-induced IL-10 production in BMDM from TLR2 knockout mice

375 was nearly abrogated (Fig. 5C).

376

377 To verify whether rCsHscB-induced IL-10 production was depended on TLR2
378 mediated ERK1/2 signaling pathway, we used an inhibitor of ERK1/2 pretreated
379 BMDM cells sourced from TLR2 wild type and TLR2 knockout mice and then
380 stimulated by 20µg/ml rCsHscB for 24 h, IL-10 production in the culture were
381 detected using ELISA. Again, the secretion of IL-10 in BMDM cells from TLR2
382 knockout mice was almost abolished when BMDM cells were stimulated by rCsHscB
383 for 24 h (Fig. 5C). For TLR2 wild type BMDM cells, it showed that there was a
384 significant decrease of IL-10 production in the BMDM cells with pretreatment of
385 PD98059, compared with the cells pretreated by DMSO (the vehicle for PD98059).
386 Furthermore, the data also demonstrated that the production of IL-10 was remarkably
387 decreased (~4 times decreased, Fig. 5C) in rCsHscB stimulated BMDM cells derived
388 from *Tlr2*^{-/-} mice compared with that from *Tlr2* wild type mice. Collectively, our data
389 demonstrated that rCsHscB induced IL-10 production in macrophage depends on the
390 activation of TLR2-depended ERK1/2 signaling.

391

392 **rCsHscB could induce IL-10 in the liver of mice dependently by TLR2 mediated**
393 **signaling pathway**

394

395 To test whether rCsHscB could induce IL-10 production mediated by TLR2/ERK1/2
396 signaling pathway *in vivo* or not, the mice with or without *Tlr2* were both received

397 rCsHscB (5 mg /kg body weight) or PBS by *i. v.* for 24 h, the levels of IL-10 in the
398 hepatic homogenate were determined. The data showed that rCsHscB induced a
399 higher level of IL-10 in the liver of mice, compared with the PBS group (Fig. 6A,
400 $P<0.01$). However, IL-10 production in the liver from *Tlr2*^{-/-} mice were significantly
401 lower than those in wild type mice when they were both received with the same dose
402 of rCsHscB (Fig. 5D, $P<0.01$), but there was no any statistic difference in IL-10 in
403 supernatant of hepatic homogenate in rCsHscB *Tlr2*^{-/-} mice and those from PBS
404 treated *Tlr2*^{-/-} mice (Fig. 5D, $P>0.05$), suggesting that rCsHscB also induced IL-10
405 production in a TLR2 dependent manner *in vivo*. Furthermore, we also found that the
406 phosphorylation of ERK1/2 in livers of *Tlr2*^{-/-} mice was also attenuated, compared
407 with *Tlr2* wild type mice following administration of the same dose of rCsHscB (Fig.
408 5E). Collectively, these data demonstrated that rCsHscB could induce IL-10
409 production mediated by TLR2/ERK1/2 signaling pathway *in vivo*.

410 *C. sinensis* has evolved complex mechanisms for resistance to immune responses.
411 Zhao et al demonstrated that total protein from *C. sinensis* inhibited Th1 immune
412 responses by activation of mannose receptor (MR), but not TLR2 or TLR4 to induce
413 Th2-skewed response [14]. Our previous study showed that TLR4 plays a regulatory
414 role in the secretion of *C. sinensis* ESPs induced type I-relative cytokines (such as
415 IFN- γ , IL-12, IL-6, TNF- α) [13]. However, the evidence suggests that the complex
416 mechanisms for host-parasites interaction during *C. sinensis* infection are still poorly
417 understood.

418 Many lipoproteins or lipo-peptide have been reported to display TLR2 ligands or

agonists activities such as *Mycobacterium tuberculosis* (Mtb) LprG [5], Mtb LprA [23], *schistosomal* lyso-PS [8] and filarial Diacyl WoLP [9]. Thus, to identify the potential TLR2 agonist sourced from *C. sinensis*, we screened the *C. sinensis* proteome data and predicted the potential lipoproteins using bioinformatic analysis. A lipoprotein from the family Co-chaperone Hsc20 (CsHscB) was ultimately selected for further study. However, it is very difficult to purify CsHscB directly from the worms due to lack of sufficient the background information as well as the low yield. We therefore used a recombinant CsHscB by *E. coli*, which was also recognized by sera of *C. sinensis* infect-mice, suggesting that rCsHscB remains the immunogenicity of *C. sinensis* rCsHscB. It was found that rCsHscB with the concentration of 5~20 µg/ml could induce a strong production of IL-10 by macrophage in a dose-dependent manner. Similarly, it have been also demonstrated that recombinant PPE18 from *M. tuberculosis* or Pam₃CSK₄ known as the TLR2 ligands also trigger the activation of macrophages and production of IL-10 in a dosed manner by specifical interaction with TLR2 [24, 25]. Therefore, 20 µg/ml of rCsHscB was used as the optimized concentration for further study.

Pull-down assay is a useful approach to verify the protein-protein interaction *in vitro*. Using this assay, Chen et al. demonstrated that recombinant MPT83 derived from *M. tuberculosis* interacts specifically with TLR2 to promote the function of macrophage [26]. Our data suggested that rCsHscB sourced from *C. sinensis* might acting as a TLR2 agonist plays a regulatory role in the immune responses to *C. sinensis* infection. However, the mechanisms by which TLR2 interact with rCsHscB

are not known due to its complexity and further studies should be warranted.

During chronic infection, parasite products trend to induce strong regulatory responses which may be in charge of balanced host-parasite interaction whereby the tissues damages were impeded and worms' survival was favored. IL-10 has been known as one of the mechanisms that contribute to induced regulatory responses induced by helminth infection [27]. For example, the increase production of IL-10 is mainly responsible for induction of CD4⁺ T cell hypo-responsiveness in the skin-draining lymph nodes after repeated exposure to *Schistosoma mansoni* larvae [28]. It is also evident that IL-10 sourced from CD4⁺CD25⁻ effector T cells impairs IFN- γ production for the control of acute inflammation and myositis in the diaphragm caused by *Trichinella spiralis* as well[29, 30]. In respect of *C. sinensis*, it showed that augment IL-10 was triggered by dendritic cells treated by *C. sinensis* crude antigen [14, 31]. Furthermore, it found that IL-10 secreted by lymphocytes from FVB was significantly higher than by those of BALB/c mice, which suggests that IL-10 may contribute to the susceptibility of different strains mice [21, 32]. In our present study, rCsHscB interacted with TLR2 can potently IL-10 production in macrophage with various concentrations (5~20 μ g/ml), which may account for mechanisms underlying production of IL-10 driven by *C. sinensis* infection.

Macrophage is one of the important sources of IL-10 in responses to TLRs or other PRRs ligands. But the intrinsic mechanisms that tailored production of IL-10 are still poorly understood. MAPKs signaling pathway (such as ERK, p38 etc) have been suggested to be involved in the control of the production of IL-10[33]. In our present

study, we found that phosphorylated ERK but not p38 was activated in the responses to the stimulation of rCsHscB for 20~30 min. Furthermore, the phosphorylated ERK1/2 was inhibited when the cells were pretreated by TLR2 blocking antibodies whereby the production of IL-10 was almost impaired, which suggest that the activation of ERK induced by rCsHscB in macrophage is mediated by TLR2. Interesting, although the production of IL-10 in rCsHscB induced cells was significantly decreased when the cells were pretreated by PD98059, these amounts were still higher than DMEM controls. To confirm these data, we also used another macrophage model-bone marrow-derived macrophage isolated from TLR2 wild and TLR2 knockout mice. Similar to our previous observation, the BMDM from TLR2 knockout mice impaired the secretion of IL-10 using the same amount of rCsHscB for stimulation, compared with those from *Tlr2*^{-/-} mice, but IL-10 secreted by rCsHscB-induced macrophages from TLR2 wild type mice were partial depressed when ERK1/2 inhibitor were pretreated. These data suggested that, in addition to ERK, other signaling pathways may be also involved in TLR2-dependent the production of IL-10 in macrophage-induced by rCsHscB. In addition, we also found that rCsHscB could induced the production of IL-10 via TLR2/ERK signaling pathway in mice following intraperitoneal injection with rCsHscB 5 mg/kg body weigh for 24 h, although there was limitation that the concentration of rCsHscB used the study might be not associated with real *C. sinensis* infection. To exclude any potential other effects of rCsHscB, we employed bull serum albumin (BSA) as a control for *in vivo* study, the data showed that BSA had little effects on the production

of IL-10 as well as the activation of p-ERK *in vivo* (the data is not shown), which demonstrated rCsHscB could specially induce high level of IL-10 both *in vivo* and *in vitro*.

In conclusion, in the present study, we identified CsHscB sourced from *C. sinensis* acting as a novel TLR2 agonist to induce potently activation of macrophage, our study also demonstrates that a robust IL-10 production by rCsHscB-induced macrophage is dependent by TLR2-mediated ERK1/2 signaling pathway, which may reveal a novel mechanism for host-parasites recognition during *C. sinensis* infection. The present study will contribute to a better understanding of the interaction between the worms and host cells. In addition, rCsHscB might be suggested in the development of novel therapeutic strategies with implications beyond parasitology due to its potential regulatory capacities of immune responses.

Author Contributions

CY and KYZ conceived and designed the experiments. FF and ZYZ performed the majority of experiments. YZ, JW, DX, HLL, YGW, QY and RXT contributed to the acquisition of data. CY and ZYZ wrote the paper. All authors read and approved the final manuscript.
