51 **Abstract**

52 Optimal selection of threat-driven defensive behaviors is paramount to an
53 animal's survival. The lateral habenula (LHb) is a key neuronal hub
54 coordinating behavioral responses to aversive stimuli. Yet, how individual LHb
55 neurons represent defensive behaviors in response to threats remains
56 unknown. Here we show that, in mice, a visual threat promotes distinct
57 defensive behaviors, namely runaway (escape) and action-locking (immobile-
58 like). Fiber photometry of bulk LHb neuronal activity in behaving animals
59 revealed an increase and decrease of calcium signal time-locked with
60 runaway and action-locking, respectively. Imaging single-cell calcium
61 dynamics across distinct threat-driven behaviors identified independently
62 active LHb neuronal clusters. These clusters participate during specific time
63 epochs of defensive behaviors. Decoding analysis of this neuronal activity
64 unveiled that some LHb clusters either predict the upcoming selection of the
65 defensive action or represent the selected action. Thus, heterogeneous
66 neuronal clusters in LHb predict or reflect the selection of distinct threat-driven
67 defensive behaviors.

73

74 **Introduction**

75 When facing an external threat, animals select from a repertoire of innate
76 behavioral responses ranging from escape (runaway) to immobile-like (action-
77 locking) strategies (Evans et al., 2019). These behaviors ultimately increase
78 individual survival, rely on the external environment, and can be adopted by
79 the same animal (De Franceschi et al., 2016; Eilam, 2005). The detection of a
80 threat and the optimal selection of such threat-driven actions (i.e. runaway or
81 action-locking) require the coordination of complex brain networks. The recent
82 analysis of threat-driven escape behaviors unraveled the essential
83 contribution of neuronal circuits including the amygdala, the superior
84 colliculus, the periaqueductal grey, the hypothalamus or the midbrain. All of
85 these are pivotal neuronal nodes for aversive processing (Evans et al., 2018;
86 Headley et al., 2019; Silva et al., 2016; Tovote et al., 2016; Zhou et al., 2019).
87 Neurons located in the epithalamic lateral habenula (LHb) signal the negative
88 valence of a stimulus contributing to aversive behaviors (Matsumoto and
89 Hikosaka, 2007). Accordingly, habenular neurons in fish, rodents and non-
90 human primates, as opposed to midbrain dopamine neurons, respond mainly
91 with an excitation to a variety of aversive stimuli, and reduce their activity after
92 reward presentation (Andalman et al., 2019; Lecca et al., 2017; Matsumoto
93 and Hikosaka, 2007; Wang et al., 2017). Specifically, aversion-driven LHb
94 neuronal excitation requires hypothalamic glutamate release to shape
95 behavioral responses upon unexpected and predicted aversive events
96 (Lazaridis et al., 2019; Lecca et al., 2017; Trusel et al., 2019). Indeed,
97 reducing the efficacy of hypothalamus-to-LHb projections impairs behavioral
98 escape driven by foot shocks, shock-predicting cues and predator-like

99 looming stimulus (Lecca et al., 2017; Trusel et al., 2019). The latter evidence
100 indicates a relevant contribution of LHb in encoding environmental threats.
101 Yet, whether specific neuronal representations in the LHb participate in the
102 selection of threat-driven defensive behaviors (runaway or action-locking),
103 remains unknown.

104

105 To examine this question, we performed deep-brain Ca^{2+} -imaging of large
106 LHb neuronal populations using a head-mounted miniaturized microscope in
107 mice engaging visual threat-driven defensive responses (Resendez et al.,
108 2016). We combined such large-scale recordings with unsupervised
109 classification of response patterns. This led to the identification of functionally
110 distinct LHb neuronal subpopulations during threat-driven runaway and
111 action-locking. Analysis of responses indicates that multiple neuronal clusters
112 emerge during behavioral strategies holding independent information (i.e.
113 prediction vs action) related to the temporal expression of the behaviors.
114 Altogether, these data support the participation of LHb neuronal populations in
115 the selection of defensive behaviors when facing an external threat.

116

117 **Results**

118 **Opposing behavioral strategies in response to a visual threat**

119 Ethological studies posit a relationship between the animal-nest distance and
120 the strategy adopted to react to a threat. The closer to a nest, the more likely
121 it is for animals to rapidly runaway to hide. Action-locking responses, instead,
122 occur with higher frequency when the animal is located far from the shelter
123 (Yilmaz and Meister, 2013).

124 Here we investigated these independent threat-driven behavioral strategies in
125 mice using an innately aversive overhead expanding spot (Looming) (Yilmaz
126 and Meister, 2013), while mice explore an experimental arena provided with a
127 nest. We randomly triggered the looming stimulus when the mouse explored
128 different zones of the arena with variable distance with respect to the nest
129 (Figure 1A and B). Mice predominantly adopted threat-driven high-speed
130 runaway responses (Figure 1A-D). In a smaller fraction of trials, however, the
131 same animals engaged in a looming-driven action-locking, a behavior outlined
132 by significant speed reduction (Figure 1A-D). Such opposite threat-driven
133 behavioral strategies related to the distance from the nest (Figure 1D).
134 Multiple looming presentations (maximum of 12) revealed comparable
135 average onset time between runaway and action-locking responses, yet
136 different offset timing, with action-locking events lasting up to tens of seconds
137 (Figure 1E). Altogether, mice can display divergent defensive behaviors to the
138 same visual threat stimulus in a context-dependent fashion.

139

140 **Threat encoding in the lateral habenula**

141 We next employed fiber photometry to measure fluorescent calcium transients
142 (Ca^{2+} ; (Cui et al., 2014)) and examined the population dynamics of LHb
143 neurons in freely behaving mice (Figure 2A). We injected rAAV2.5-hSyn1-
144 GCaMP6f into the LHb and implanted an optical fiber above the injection site
145 (Figure 2A and Figure 2– figure supplement 1A). The onset of threat-driven
146 runaway occurred along with a robust increase in Ca^{2+} fluorescence from LHb
147 neurons (Figure 2A, B and movie 1). In contrast, looming-driven action-locking
148 developed together with a significant reduction in LHb fluorescence (Figure

149 2A, B and movie 2). Notably, a significant shift in fluorescence emerged time-
150 locked with the visual looming stimulus and prior the behavior (Figure 2–figure
151 supplement 1B, C). The magnitude of this fluorescence rise was comparable
152 between runaway and action-locking trials (Figure 2–figure supplement 1B,
153 C). The observation that no fluorescence transients occurred in animals
154 injected only with a rAAV2.5-hSyn1-GFP, supports the specificity of signal
155 detection (Figure 2–figure supplement 2A, B). Both runaway and action-
156 locking expressed along with an abrupt change in speed at the behavioral
157 onset (Figure 1C). However, speed changes outside the looming presentation
158 did not coincide with fluorescence transients, supporting that spontaneous
159 locomotion does not engage LHb activity (Figure 2–figure supplement 3A, B;
160 (Lecca et al., 2017)). Altogether, these data suggest that a threat recruits
161 differential LHb neuronal responses throughout the expression of diverse
162 behavioral strategies (i.e. from stimulus detection to action completion).

163

164 **Heterogeneity of habenular neuronal activity emerges during defensive** 165 **behaviors**

166 Analysis of neuronal function with fiber photometry (Figure 2A, B) lacks
167 cellular-level resolution, and provides only aggregated activity from large
168 neuronal populations (Resendez et al., 2016). Such limitation can be
169 circumvented through the use of gradient-refractive-index (GRIN) lenses,
170 which enable visualization of deep-brain neuronal activity with single-cell
171 resolution. We next examined how individual LHb neurons represent threats
172 via their activity patterns. We used a miniature fluorescence microscope to
173 track the relative changes in Ca²⁺ fluorescence in LHb neurons in freely

174 moving mice during threat-driven behaviors (Figure 3A; 62 ± 14.6 neurons per
175 animal; $n_{\text{mice}} = 4$). Lhb neurons exhibited diverse activity patterns, with sharp
176 elevations in Ca^{2+} fluorescence during runaway. The response was in the
177 opposite direction during action-locking trials (Figure 3B and Figure 3–figure
178 supplement 1A). The average Ca^{2+} signal across all neurons recorded from a
179 single animal recapitulated the response profiles observed with photometric
180 analysis, supporting the validity of these experimental approaches (Figure 3B,
181 Figure 3–figure supplement 1A and Figure 2B). Thus, single cell analysis of
182 Ca^{2+} signal indicates that opposite neuronal responses in the Lhb reflect
183 independent threat-driven behavioral strategies.

184

185 Individual Lhb cells displayed variable profiles of runaway-excited/action-
186 locking inhibited responses (Figure 3–figure supplement 1A, B). Furthermore,
187 the activity of single neurons during a given defensive strategy across trials
188 was also variable (Figure 3–figure supplement 1C). Altogether, this argues in
189 favor of functional heterogeneity across Lhb neuronal responses after threat.
190 We thereby used an unsupervised clustering algorithm to group the trial-
191 averaged time-locked response of each cell after runaway and action-locking
192 onset ($n = 248$ from $n = 4$ mice; Figure 3C and Figure S4A). This analysis
193 revealed eight clusters of neurons based on their responses surrounding the
194 behavioral onset (Figure 3C, Figure 3–figure supplement 2A, B). Clusters
195 were represented in each animal, supporting the strength of independent
196 neuronal representations (Figure 3–figure supplement 2C). The responses of
197 clusters 1 to 5, qualitatively recapitulated fiber photometry Ca^{2+} dynamics
198 time-locked to runaway and action-locking onset (Figure 3C). Cluster 7 and 8,

199 instead, were weakly modulated during looming-triggered defensive
200 responses. Interestingly, Clusters 3 and 6 stood out as their pre-action Ca^{2+}
201 dynamics discriminated the upcoming behavior (Figure 3C). Altogether, this
202 supports the existence of distinct clusters of individual neurons participating
203 throughout threat-driven behavioral responses.

204

205 **Decoding the contribution of habenular clusters to threat-driven** 206 **behaviors**

207 The existence of clusters with neuronal activity that distinguishes the
208 defensive behaviors *prior* to the onset of the action (especially 3 and 6)
209 raised the intriguing possibility that LHb neurons may predict the upcoming
210 selection of runaway or action-locking. To test this idea, we examined the
211 neuronal coding of LHb ensembles by testing whether the defensive strategy
212 on a given trial was identifiable from individual neuron activity patterns (Figure
213 4A). We defined three time epochs as “prediction of action” (-3 to 0 s from
214 action), “immediate action” (0 to 3 s from action), and “delayed action” (3 to 6
215 s from action) (Figure 4B). Using leave-one-out cross-validation of a Naïve
216 Bayes classifier (Namboodiri et al., 2019), we calculated the decoding
217 accuracy per neuron above the chance decoding obtained when shuffling trial
218 identity. We then averaged these accuracies across all recorded neurons
219 (Figure 4C) or across all neurons within a cluster (Figure 4D). The null
220 hypothesis was that the average decoding accuracy (above chance) per
221 timeframe and (sub)population is zero. We found that the average decoding
222 accuracy across all recorded neurons was significant for each time epoch
223 (Figure 4C). Interestingly, decoding accuracies showed cluster-specific

224 patterns. Most notably, we found that clusters 3 and 6 showed significant
225 decoding (after correcting for multiple comparison) during the “prediction of
226 action” epoch, whereas other clusters (also including cluster 3) showed
227 significant decoding after the action (Figure 4D). Matching the cluster identity
228 with the topographical neuronal localization during the recordings, revealed
229 that the clusters related to prediction, (clusters 3 and 6), were located caudally
230 with respect to the rest of the clusters (Figure 3–figure supplement 2D).
231 Overall, these results demonstrate that distinct neuronal subpopulations within
232 the LHb either predict or reflect defensive behavioral selection in response to
233 a threat.

234

235 **Discussion**

236 **Dissecting specific contribution of LHb activity for aversion**

237 The past decade witnessed exponentially growing interest in the essential role
238 the LHb has in regulating negatively motivated behaviors. It is of a general
239 consensus within the field that LHb neurons are a homogenous population of
240 glutamatergic cells mostly controlling the function of neuromodulatory systems
241 (Meye et al., 2013). It is also largely accepted that LHb neurons are uniformly
242 excited by aversive external stimuli (Lecca et al., 2017; Matsumoto and
243 Hikosaka, 2007; Wang et al., 2017). Here, we challenge this vision of
244 homogeneity showing that in response to an identical aversive stimulus (the
245 looming), LHb cells dynamics follow opposite logic in a behavior-dependent
246 manner: an escape reaction (runaway) recruits mainly an activation of LHb
247 cells. In contrast, action-locking responses occur along with a decrease in
248 calcium activity, potentially reflecting neuronal inhibition (Namboodiri et al.,

249 2019; Shabel et al., 2019; Wang et al., 2017). Accordingly, aversive foot-
250 shock inhibited neuronal activity of a small and territorially distinct subset of
251 LHb cells (Congiu et al., 2019). Based on this, future work should avoid
252 generalizing that LHb contribution to aversion encoding solely relates to its
253 excitation. Notably, the opposite responses emerging after the looming can
254 occur within the same neuron. It is therefore plausible that a given external
255 stimulus drives dissimilar responses in single cells. The substrate (i.e.
256 connectivity or gene) enabling such neuronal population to encode both
257 behavioral aspects remains however an open question.

258

259 **Functional heterogeneity in LHb for threat-driven behaviors**

260 On the basis of recordings and analysis of around 250 LHb cells while
261 animals experience a threat, here we show how ensembles of neurons
262 represent threat-driven behavioral defensive strategies. An unsupervised
263 clustering reveals that independent sets of active neurons form during the
264 expression of threat-mediated behavioral responses (Gründemann et al.,
265 2019; Namboodiri et al., 2019). Such discrete neuronal clusters are stable and
266 define timeframes of threat detection and behavioral action (Gründemann et
267 al., 2019). It remains unclear however which neurobiological substrate defines
268 LHb clusters. Within the amygdala and the cortex, genetically distinct
269 neuronal subtypes contribute to different phases of adaptive behaviors (Abs et
270 al., 2018; Douglass et al., 2017; Krabbe et al., 2019). Recent studies identified
271 molecular-level neuronal diversity within the LHb (Wallace et al., 2019;
272 Hashikawa et al., 2019). Exploiting this genetic knowledge may provide an
273 entry point to specifically probe the functional and behavioral relevance of

274 individual LHb neuronal clusters identified in this study. Alternative to a
275 genetic basis, clusters may emerge according to topographical organization,
276 input-specific connectivity or discrete projection targets (Cerniauskas et al.,
277 2019; Lecca et al., 2017; Meye et al., 2016; Shabel et al., 2012; Valentinova
278 et al., 2019). Our analysis indicates that some LHb neuronal clusters are
279 topographically distinct. This heightens the need of future studies to address
280 this unresolved questions. Notably, the multilevel heterogeneity (functional,
281 anatomical, molecular) emerging lately replaces the initial uniform connotation
282 attributed to the LHb. Further studies will need to determine the relationship
283 across these multiple levels of heterogeneity and establish their behavioral
284 relevance.

285

286 **Complex neuronal networks for defensive behaviors**

287 The initial observation that limiting excitation onto LHb impairs escape
288 behaviors implicated this structure in the encoding of innate escape (Lecca et
289 al., 2017). An original aspect of the present work lies on the demonstration
290 that LHb activity changes when animals escape or action-lock after looming
291 presentation. In contrast, recent studies support the contribution of several
292 midbrain nuclei mostly for threat-driven escape (Evans et al., 2018; Seo et al.,
293 2019). Indeed, Ca²⁺ imaging and brain circuit manipulation approaches
294 demonstrate that glutamatergic neurons of the dorsal periaqueductal grey
295 encode decision making and escape (Evans et al., 2018). In addition, a visual
296 pathway engaging superior colliculus and amygdala also contributes to
297 defensive strategies (Shang et al., 2018). Finally, GABAergic neurons in the
298 ventral tegmental area (VTA) projecting to the central amygdala (CeA) seem

299 to be similarly instrumental for threat-driven escape responses (Zhou et al.,
300 2019). Intriguingly, LHb axons innervate these VTA-GABA cells projecting to
301 CeA. Future studies should test how diverse defensive strategies engage
302 wide interconnected networks activity to ultimately build an integrated
303 framework for threat-driven behavioral responses. Defensive strategies are a
304 combination of behavioral sets relying on unique features including
305 trajectories, or stereotyped movements (Evans et al., 2019). The use of deep
306 neural network analysis tracking facets of animal behaviors (Nath et al., 2019;
307 Wiltschko et al., 2015) may pave the way to differentiate precise aspects of
308 defensive behaviors. This will allow a refined alignment with the neuronal
309 dynamics in defined neuronal circuits (Klaus et al., 2017).

310

311 The relationship between LHb function and optimal selection of defensive
312 strategies remains correlative after the analysis of the photometric signal. Yet,
313 the unsupervised clustering and decoding analysis support: *i.* that LHb activity
314 codes for distinct behavioral strategies, *ii.* that the dynamics of discrete LHb
315 neuronal clusters reflect precise time epochs of defensive behaviors and *iii.*
316 that these clusters can predict upcoming selection of the action or represent
317 an action itself (Grewe et al., 2017; Namboodiri et al., 2019). Opto or
318 chemogenetic interrogation of LHb neuronal population offers a mean to
319 probe causality between neuronal activity and behaviors (Saunders et al.,
320 2015). However, this intervention is challenging in the present context, as it is
321 limited by the lack of population-specific viral targeting within LHb (i.e. lack of
322 genetic tools for LHb diversity). The manipulation of LHb function in a non
323 cell-specific fashion remains a poor approach to test for causality. This would

324 not fulfill the requirement of precise neuronal cluster targeting, a feature
325 highlighted in the functional and topographical analysis provided in this work.
326 The latest insights of genetic profiling may soon provide the tools to assess
327 these outstanding questions.

328

329 In summary, our results identify the evolution of individual neuronal responses
330 in a deep structure like the LHb during threat-driven behavioral strategies, an
331 objective so far proven challenging due to technical difficulties. We
332 demonstrated that LHb neuronal clusters participate to the optimal selection of
333 defensive strategies. Future studies can provide a link between this functional
334 heterogeneity with genetic and anatomical aspects to establish a
335 comprehensive knowledge of LHb contribution to threat encoding. Altogether,
336 these findings advance our understanding of the neuronal basis of
337 ethologically-relevant innate behaviors.

338

339 **Contributions**

340 S.L. and M.M. conceptualized the project. S.L. performed and analyzed
341 behaviors and in vivo calcium imaging. L.R. provided support for behavioral
342 analysis and experiments. N.G. performed independent calcium imaging
343 analysis. G.P. provided analytical support for the photometric detection.
344 V.M.K.N. and G.D.S. provided support, and analysis for calcium imaging
345 analysis and help in editing the manuscript. M.M. and S.L. wrote the
346 manuscript with the help of all authors.

505 **Figure legends**

506 **Figure 1. Threat exposure promotes divergent defensive strategies.**

507 (A) Schematic of the looming protocol.

508 (B) Extracted video frames depicting a mouse during looming-driven runaway
509 (top) and action-locking (bottom).

510 (C) Representative single mouse runaway and action-locking trials to multiple
511 looming stimuli.

512 (D) Top: representative track of a single mouse during a runaway and an
513 action-locking trials. Bottom: strategy probability in function of the mouse-nest
514 distance ($n_{\text{runaway trials}} = 56$; $n_{\text{action-locking trials}} = 23$; $n_{\text{mice}} = 11$; *Mouse-nest distance*
515 (*Max distance = 1*): R trials vs AL trials; 0.3: 4 vs 0; 0.4: 7 vs 0; 0.5: 8 vs 0;
516 0.6: 10 vs 2; 0.7: 11 vs 0; 0.8: 9 vs 6; 0.9: 3 vs 3; 1.0: 4 vs 12; $X^2_7 = 31.68$;
517 *** $p < 0.0001$, Chi Square test). The lines fitting a sigmoidal distribution reports
518 the correlation between the mouse-nest distance and the selected strategy
519 (Runaway: $r = -0.883$, $R^2 = 0.78$, ** $p = 0.003$; Action-locking: $r = 0.884$,
520 $R^2 = 0.78$ ** $p = 0.003$, Pearson correlation coefficient)

521 (E) Left: Single mouse runaway (R, in red) and action-locking (AL, in blue)
522 timeframe reported for each trial (dot: onset response, line: offset response).
523 Right: pooled data ($n_{\text{runaway trials}} = 56$; $n_{\text{action-locking trials}} = 23$) for onset (R vs AL;
524 1.631 ± 0.14 vs 1.797 ± 0.34 s; $t_{77} = 0.53$; $p = 0.59$, unpaired t-test) and duration
525 (R vs AL; 1.52 ± 0.14 vs 9.58 ± 2.37 s; $t_{77} = 5.29$; *** $p < 0.0001$, unpaired t-test)
526 of runaway and action-locking.

527 Data are presented with boxplots (median and 10-90 quartile) or mean \pm
528 S.E.M.

529

530 **Figure 2. Opposite habenular neuronal dynamics during divergent**
531 **defensive strategies.**

532 (A) Top: schematic of the experiment. Bottom left: representative brain
533 coronal section showing GCamp6f transduction and the fiber implantation
534 track in the LHb. Bottom right: representative Ca^{2+} traces during runaway (R,
535 red, top) and action locking (AL, blue, bottom) trials (Looming, gray bar).
536 (B) Top, time-course of averaged traces and boxplots reporting respectively
537 normalized photons (R = 56 trials, $F_{3850} = 50.88$, $***p < 0.0001$; AL=23 trials,
538 $F_{1540} = 3.642$, $*p = 0.012$; RM One way ANOVA) and area under the curve (R vs
539 AL, 11.70 ± 5.95 vs -12.96 ± 6.85 ; $t_{77} = 2.40$, $*p = 0.019$, Unpaired t-test) for
540 single trials aligned to the behavioral onset.
541 Bottom: same as top but aligned to the offset (R: $F_{3850} = 65.71$, $***p < 0.0001$;
542 AL: $F_{1540} = 6.79$, $***p < 0.0001$; RM One way ANOVA; AUC analysis: R vs AL, -
543 42.07 ± 4.01 vs 26.16 ± 5.71 ; $t_{77} = 9.401$, $***p < 0.0001$, Unpaired t-test).
544 Data are presented with boxplots (median and 10-90 quartile) or mean \pm
545 S.E.M.

546

547 **Figure 3. Distinct LHb neuronal ensembles during defensive behaviors**

548 (A) Top: schematic of the experiment. Bottom, pictures showing mouse with
549 miniscope attached, GRIN lens placement, GCaMP6f expression, field of view
550 with identified cells (max intensity projections), map of active LHb neurons
551 and respective sample traces (right).
552 (B) Mean Ca^{2+} responses (z-score) across runaway (left) and action locking
553 (right) trials for 46 LHb neurons imaged within a single mouse, aligned to the
554 onset of the behavioral reaction. Highlighted on the top, the average response

555 of a single cell (Cell ID: 15) . Bottom, averaged time-course of all cells for
556 runaway and action locking strategies.

557 (C) Cluster identification by unsupervised classification during runaway (top)
558 and action-locking (center) including all neurons recorded. Bottom, average
559 trace across all neurons within cluster. Plots are aligned to the action onset.
560

561 **Figure 4. Identified LHb neuronal clusters code for behavioral**
562 **preparation and execution**

563 (A) Single cell activity across trials during runaway and action locking reported
564 as heat plots (left) and mean z-score (right). Note, trials are time-locked with
565 the behavior and presented different onset due to trial by trial variability in
566 reaction time (blank spaces in the heat plots)

567 (B) Workflow for decoding analysis of single neurons activity. The decoder
568 was run in three different time epochs (-3 to 0 s, burgundy bar; 0 to 3 s, green
569 bar; 3 to 6 s yellow bar) relatively to the behavioral onset.

570 (C) Single cell decoding accuracy above chance averaged across all recorded
571 neurons. Red dots highlights significance above chance. Error bars reflect
572 standard error of the mean. $t_{247} = 3.23$ for -3 to 0 s, $t_{247} = 9.37$ for 0 to 3 s, t_{247}
573 $= 7.54$ for 3 to 6 s; p values for the three epochs = 2.67×10^{-3} , 1.56×10^{-18} and
574 6.84×10^{-13} after Benjamini-Hochberg multiple comparisons correction across
575 all epochs.

576 (D) Decoding results split by the clusters. Red dots highlights significance
577 above chance. $t_{247} = (0.44, 0.12, 2.54, 1.20, 0.35, 2.58, 0.78, 1.94)$ for the 8
578 clusters for -3 to 0 s, $t_{247} = (6.62, 5.03, 4.16, 4.20, 2.07, -0.19, 2.25, 4.33)$ for
579 the 8 clusters for 0 to 3 s, $t_{247} = (3.13, 8.66, 2.99, 4.43, 3.27, -2.44, 2.42, 1.67)$

580 for the 8 clusters for 3 to 6 s; p values for the three epochs per cluster =
581 $(7.55 \times 10^{-1}, 9.07 \times 10^{-1}, 2.99 \times 10^{-2}, 2.96 \times 10^{-1}, 7.97 \times 10^{-1}, 2.63 \times 10^{-2}, 5.28 \times 10^{-1},$
582 $7.91 \times 10^{-2})$ for -3 to 0 s, $(2.87 \times 10^{-7}, 4.07 \times 10^{-5}, 5.35 \times 10^{-4}, 3.39 \times 10^{-4}, 6.54 \times 10^{-2},$
583 $4.43 \times 10^{-1}, 4.54 \times 10^{-2}, 1.89 \times 10^{-4})$ for 0 to 3 s, and $(7.78 \times 10^{-3}, 1.18 \times 10^{-10},$
584 $1.12 \times 10^{-2}, 1.89 \times 10^{-4}, 5.67 \times 10^{-3}, 9.84 \times 10^{-1}, 3.22 \times 10^{-2}, 1.31 \times 10^{-1})$ for 3 to 6 s
585 after Benjamini-Hochberg multiple comparisons correction across all clusters
586 and epochs.

587

588

589

590

591 **Supplementary figures legends**

592

593 **Figure 2–figure supplement 1. Looming-locked shift in LHb Ca²⁺ signal**
594 **occurs prior runaway and action-locking**

595 (A) Schematic of fiber placement in the LHb (brown rectangles represent fiber
596 tip placement)

597 (B) Representative averaged traces and boxplots for Runaway (R, 56 trials)
598 and Action-locking (AL, 23 trials) reporting the slope 0.5 s before the
599 behavioral onset (R vs AL, 0.030 ± 0.012 vs 0.032 ± 0.015 , $t_{77}=0.127$, $p=0.91$
600 Unpaired t-test)

601 (C) Normalized photon traces and area under curve showing the LHb activity
602 time-locked with the looming onset for Runaway (51 trials, $F_{480}= 4.10$;
603 $***p<0.0001$, RM One way ANOVA) and Action-locking trials (18 trials, $F_{153}=$
604 2.45 ; $**p=0.002$, RM One way ANOVA). Boxplots reported the AUC for the
605 same set of data (R vs AL, 0.87 ± 0.22 vs 0.63 ± 0.15 ; $t_{67}= 0.612$, $p=0.54$
606 Unpaired t-test). Note that for this analysis trials displaying a behavioral onset
607 < 0.5 sec were discarded to avoid behavior-dependent signal contamination.
608 Data are presented with boxplots (median and 10-90 quartile) or mean \pm
609 S.E.M.

610

611 **Figure 2–figure supplement 2. Lack of fluorescent transients in absence**
612 **of GCamp6f expression.**

613 (A) Schematic of the experiment and representative brain coronal section
614 showing eGFP injections in the LHb ($n_{mice}= 5$).

615 (B) Left: Normalized photons time-course graph showing averaged traces of
616 Runaway (R, $n_{\text{trials}}=21$, $F_{1400}=2.46$, $p=0.065$, RM One way ANOVA) and
617 Action-locking (AL, $n_{\text{trials}}=12$, $F_{770}=0.946$, $p=0.401$ RM One way ANOVA)
618 trials time-locked with the behavioral onset. Right: area under curve (AUC) for
619 the same data set (R vs AL, 2.662 ± 1.96 vs -0.6096 ± 2.18 ; $t_{31}=1.063$,
620 $p=0.295$, Unpaired t-test).

621 (C) Same as (B) but trials are locked with the offset of the behavior (R:
622 $F_{1400}=0.83$, $p=0.394$; AL: $F_{770}=0.906$, $p=0.452$; RM One way ANOVA. AUC
623 analysis: (R vs AL, 1.051 ± 1.58 vs 0.3684 ± 2.24 ; $t_{31}=0.253$, $p=0.801$ Unpaired
624 t-test).

625 Data are presented with boxplots (median and 10-90 quartile) or mean \pm
626 S.E.M.

627

628 **Figure 2—figure supplement 3. LHb neuronal Ca^{2+} transients are**
629 **independent of locomotion.**

630 (A) Representative traces and boxplots reporting increase in speed (Looming
631 on vs Looming off; 11 vs 11; 4.1 ± 0.56 vs 3.3 ± 0.28 pixel/frame; $t_{20}=1.28$,
632 $p=0.21$ Unpaired t-test) and the relative LHb activity (Looming on vs Looming
633 off; 11 vs 11, 1.19 ± 0.02 vs 1.00 ± 0.012 normalized photon; $t_{20} = 7.35$,
634 $***p < 0.0001$ Unpaired t-test) in presence or absence of the looming stimulus.

635 (B) Same as (A) but for decrease in speed (Looming on vs Looming off; 10 vs
636 10; -0.7558 ± 0.10 vs -0.9987 ± 0.176 pixel/frame; $t_{18}=1.190$, $p=0.249$
637 Unpaired t-test) and relative LHb photon change (Looming on vs Looming off;
638 10 vs 10, 0.9204 ± 0.014 vs 0.9807 ± 0.007 normalized photons; $t_{18}=3.61$,
639 $**p=0.002$ Unpaired t-test).

640 For this comparison, we selected the first runaway and action locking
641 response for each mouse. Then we looked for a single episode outside
642 looming presentation with a comparable change in speed for the same
643 mouse. Note that one mouse did not display any action locking response
644 throughout the recording session.
645 Data are presented with boxplots (median and 10-90 quartile) or mean \pm
646 S.E.M.

647

648 **Figure 3—figure supplement 1. Opposite threat-driven responses occur**
649 **in the same LHb neuronal ensemble**

650 (A) Mean Ca^{2+} responses for runaway (left) and action-locking (right) trials
651 time-locked with the behavioral onset, including all cells recorded in 4 mice
652 (n=248). Cells are sorted for response magnitude in runaway trials.
653 On the bottom, runaway- and action-locking-locked averaged signals. Data
654 are reported as z-score.
655 (B) On the top, heat-map showing the cell distribution in the different
656 categories according to their response to runaway and action-locking
657 (Runaway/Action-locking: excited/inhibited=73, excited/non responsive=47,
658 excited/excited=4, non responsive/inhibited=62, non responsive/non
659 responsive=35, non responsive/excited=16, inhibited/inhibited=6,
660 inhibited/non responsive=4, inhibited/excited=3). On the bottom, correlation
661 analysis of single cell average Ca^{2+} responses (z-score) to runaway vs action
662 locking displaying variability (Runaway vs Action-locking; $n_{\text{cells}}=248$, $r=-0.208$;
663 $R^2=0.043$; $***p<0.0001$, Pearson correlation coefficient).
664 (C) Top: Raster plots showing active (red squares) and non-active cells

665 (black squares), imaged over different runaway trials in a single mouse. On
666 the right, the boxplot reports single cell reliability (%) for runaway responses
667 ($n_{\text{cells}}=248$, Runaway, $38.01 \pm 1.3\%$). Bottom, same mouse as top. Raster
668 plots showing cells inhibited (red squares) or not (black squares), imaged over
669 different action-locking trials. On the right, the boxplot show reliability for
670 single cells in percentage for action-locking reposes ($n_{\text{cells}}= 248$, Action-
671 locking, $32.71 \pm 1.37\%$).

672

673 **Figure 3—figure supplement 2. Cluster detection and topography during**
674 **runaway and action-locking**

675 (A) Plot of the percentage variance explained per principal component,
676 showing the number of principal components retained (dashed line).

677 (B) Individual retained principal components, showing response vectors to
678 both runaway and action-locking trials.

679 (C) The graph reports the percentage of cells in each cluster (Cluster 1 to 8,
680 number of cells per cluster: 26, 30, 22, 33, 28, 35, 29, 45) and single-mouse
681 contribution per cluster (Cluster 1 to 8, number of cells per cluster. Mouse 1:
682 16, 10, 0, 7, 3, 6, 7, 3. Mouse 2: 4, 4, 12, 8, 9, 22, 5, 10. Mouse 3: 4, 9, 0, 8,
683 1, 1, 0, 4. Mouse 4: 2, 7, 10, 10, 15, 6, 17, 28).

684 (D) Topographical distribution of the clusters in LHb (action-predictive vs
685 action-decoding clusters; rostral vs caudal cell distribution; Action-predictive:
686 57 cells, 9 rostral vs 48 caudal. Action-decoding: 191 cells, 83 rostral vs 108
687 caudal. $X^2= 14.4$; $z=3.79$; $***p=0.0001$, Chi-Square test).

688

689

690 **Material and methods**

691 **Experimental subjects**

692 The experiments were performed on C57Bl/6J mice wild-type males of 10-18
693 weeks. Mice were housed at groups of five per cage with water and food ad
694 libitum on a 12:12 h light cycle (lights on at 7 a.m.). All procedures aimed to
695 fulfill the 3R criterion and were approved by the Veterinary Offices of Vaud
696 (Switzerland; License VD3171).

697

698 **Behavioral paradigm**

699 Mice were tested for behavior in a looming visual stimulus test, as described
700 elsewhere (Yilmaz and Meister, 2013). Animals were placed in an open-top
701 plexiglas box (58cm Lx 38cm Wx 32cm H). A triangular shaped nest (20 × 12
702 cm) was placed in one corner. Recordings were performed under illumination
703 provided by the projector screen (52 cm × 30 cm; Dell) and an infrared light-
704 emitting diode (LED) illuminator (Pinnacle Technology), both placed above the
705 arena. Experiments were recorded at 60 frames per second with a near-IR
706 GigE camera (acA1300-60gmNIR, Basler) positioned in one side of the arena.
707 Video recording, was controlled with Ethovision and synchronized with the
708 photometric and endoscopic recordings using hardware-time signals
709 controlled with a I/O box (Noldus). All the mice tested underwent a period of
710 habituation to the fiber/camera spanning from 15-20 min session every day for
711 3 consecutive days. For the experiment, after 5-10 min of acclimatization, a
712 looming stimulus (always delivered at 50% contrast), was randomly presented
713 from the screen in the center of the arena while the mouse was actively
714 exploring (independently by its position in the arena). The stimulus of 0.5 s

715 duration was repeated 5 times with an inter-stimulus interval of 0.5 s. Each
716 mouse received from 7 to 20 trials with a minimum inter-trial interval of about
717 5 minutes. The video analysis of the behavior was performed off-line.

718

719 *Automated detection of mouse shape and position.* A fully convolutional
720 neural network was used to extract the shape of the mouse across the arena.
721 Each video (1920 x 1088 @ 60 fps) was converted to a sequence of images
722 (8-bit, 256 x 144 pixel). The training dataset was composed of 112 images
723 and it was used to trace a set of 112 masks (8-bit, 256 x 144 pixel binary
724 images) delineating the contour of the mouse body and to output the files
725 storing the coordinates of the center of mass of each individual mask. Each
726 image in the training dataset was passed through three convolutional layers
727 (channels: 16, 32, 64; kernels: 3, 5, 3, stride: 1, ReLU units), two max-pooling
728 operations (kernel size: 2), and three transposed convolutional layers. The
729 frames were processed in batches of 64 images for 171 epochs). The network
730 was built with the open source library PyTorch 1.2 (<https://pytorch.org/>) and
731 trained to minimize (Adam optimizer, learning rate: 0.003) the Mean-Squared
732 Error loss function. Accuracy was measured as the Euclidean distance
733 between the centroid of the mask of the training set and the centroid of the
734 score map predicted by the network. An arbitrary cutoff was used to define
735 the boundaries of the estimated mouse shape on the score map. The mean
736 accuracy on the test set was 1.65 px (+/- 1.51 px, standard deviation), with
737 96.4% of the frames showing a distance between centroids (i.e. label Vs
738 predicted) less than 7 px. The output coordinates of the center of mass were
739 then used to compute the speed (pixels/seconds) and the location of the

740 mouse inside the arena. The onset of runaway was measured as the peak of
741 the first derivative of the mouse speed tracking curve. The runaway offset was
742 coinciding with the mouse entrance in the nest. The score map was used to
743 estimate the size of the mouse (e.g. total number of pixel above the arbitrary
744 threshold) across the arena and used for further calculations to score action-
745 locking behavior.

746

747 *Automated classification of action-locking behavior.* An observer blind to the
748 experimental condition of the animals manually scored the action locking
749 behavior, defined as a sudden blockade of all -except respiratory-
750 movements. In contrast to freezing, action locking was not associated with a
751 particular body posture (i.e. crouching). The sudden immobility had to last at
752 least two seconds in order to score the animal as actively producing an
753 action-locking behavior. Data obtained from the manually labeled frames were
754 then merged with the data (speed and size) obtained from the automatic
755 detection of the mouse position to train a random forest classifier to predict in
756 each frame whether the animal was in action-locking. Both speed and size
757 were convolved with a Max function (window = 60 frames) and a total of four
758 features were used: speed (v), size (s), es, and ev. A 5-fold cross-validation
759 yielded an overall accuracy of 98%. The accuracy achieved on the test set
760 was 97.5% with a false positive rate of 2.6%.

761

762 **Surgical procedures**

763 *Viral injections.* All mice were anaesthetized with ketamine (150
764 mg/kg)/xylazine (10 mg/kg) (Sigma-Aldrich, France). We unilaterally injected

765 in the LHb (-1.4 mm AP, 0.45 ML, 3.1 mm DV) rAAV2.1-hSyn-GCaMP6f-
766 eGFP or rAAV/DJ-hSyn- -GCaMP6f-eGFP or rAAV2.5-hSyn-eGFP (University
767 of North Carolina, US) using a glass pipette on a stereotactic frame (Kopf,
768 France). Volumes ranged between 200 and 300 nl, at a rate of approximately
769 100-150 nl/min. The injection pipette was withdrawn from the brain 10 minutes
770 after the infusion. Animals were allowed to recover for a minimum of two
771 weeks before fiber or GRIN lenses implantation.

772

773 *Chronic implants.* For fiber photometry experiments, a single fiber probe was
774 placed and fixed (C and B Metabond, Parkell) 150 μ m above the injection site
775 in isoflurane anesthetized (induction: 4%, maintenance: 1.8-2%) mice.
776 For endoscope experiments, mice were anaesthetized (as described above)
777 and implanted with a GRIN (Graded-Index) lens (6.1mm length, 0.5mm
778 diameter; Inscopix, #100-000588). The lens was targeted to be ~ 150–200 μ m
779 above the injection site using the following coordinates: -1.40 mm posterior to
780 bregma, 0.45 mm lateral from midline, and -2.85 to -2.9 mm ventral to skull
781 surface (lowered at a speed of 1 μ m/s). To increase stability of the implants
782 the lenses were implanted into the dorsal portion of the region allowing
783 imaging ventral LHb neurons. Two week after lens implantation, mice were
784 again anaesthetized (isoflurane, as above) and a baseplate (Inscopix, #100-
785 000279) was secured above the lens. A baseplate cover (Inscopix, #100-
786 000241) was attached to prevent damage to the microendoscope lens. Out of
787 23 mice that were injected with GCaMP6f virus, 4 had successful lens
788 implantation/viral expression and were used for this study.

789

790 **Fiber photometry recordings**

791 Fiber photometry measurements were carried out by the ChiSquare X2-200
792 system (ChiSquare Biomaging, Brookline, MA). Briefly, blue light from a 473-
793 nm picosecond-pulsed laser (at 50 MHz; pulse width ~ 80 ps FWHM) was
794 delivered to the sample through a single mode fiber. Fluorescence emission
795 from the tissue was collected by a multimode fiber with a sample frequency of
796 100Hz. The single mode and multimode fibers were arranged side by side in a
797 ferrule that is connected to a detachable multimode fiber implant. The emitted
798 photons collected through the multimode fiber pass through a bandpass filter
799 (FF01-550/88, Semrock) to a single-photon detector. Photons were recorded
800 by the time-correlated single photon counting (TCSPC) module (SPC-130EM,
801 Becker and Hickl, GmbH, Berlin, Germany) in the ChiSquare X2-200 system.

802

803 **Endoscope recordings**

804 All calcium imaging was recorded at 20 frames per second, 200-ms exposure
805 time, and 10–40% LED power (0.4-0.9mW at the objective, 475nm) using a
806 miniature microscope from Inscopix (nVista). Calcium recording files were
807 down-sampled (spatial binning factor of 4) to reduce processing time and file
808 size, filtered, corrected for rigid brain movement and the $\Delta F/F_0$ was
809 calculated using as F_0 the average fluorescence for all the video (Inscopix,
810 IDP). Individual component analysis and principle component analysis
811 (ICA/PCA) applications were used to identify individual cells and to extract
812 their respective calcium traces.

813 In addition, to compare ROI detections and relative traces obtained with the
814 PCA/ICA we also performed constrained non-negative matrix factorization for

815 endoscopic data (CNMF-E) for a subset of data. Briefly, we denoised,
816 deconvolved, and demixed calcium-imaging dynamics
817 (http://www.github.com/zhoup/cnmf_e). This method allows accurate single
818 neurons fluorescence traces extraction (Zhou et al. 2018). Calcium imaging
819 frames were initially pre-processed in Mosaic (Inscopix) for motion correction.
820 We use a Gaussian kernel width 4 μm , maximum soma diameter 16 μm ,
821 minimum local correlation 0.8, minimum peak-to-noise ratio 8 and merging
822 threshold was set to 0.65 for optimal discrimination of temporal and spatial
823 overlap.

824

825 **Analysis**

826 Photometric signal as well as ICA/PCA derived traces were smoothed
827 (constant time factor, 0.1 s) and further processed according to the trials using
828 Spike2 software (Cambridge Electronic Design). We obtained an average
829 peri-stimulus time histogram (PSTH) trace aligned to the stimulus or
830 behavioral onset/offset (3 s prior and 7 sec after a given event). For the
831 photometric recordings we calculate the photon change normalizing for the 3
832 sec prior each trial. For the endoscope recordings we z-scored each trials in
833 reference to their baseline (3 s prior to behavior onset).

834 We identified functional sub-classes of neurons by comparing the
835 fluorescence Ca^{2+} signals of individual cells before and after a given event,
836 using 2s time span. For runaway trials we consider a cell excited if the signal
837 2 s post runaway onset was higher than the baseline plus 2 SD. Vice versa a
838 cell was inhibited if its signal in the 2s post runaway resulted 2 SD lower than
839 their baseline. For action-locking responses we considered 3 epochs (2s each

840 epoch) of analysis post event according with the average duration of this
841 behavior (6s). If the signal in at least one epoch resulted higher or lower than
842 2 SD of the baseline the cell was considered action-locking excited or
843 inhibited respectively.
844 For the analysis of the single trials we follow the same logic above-mentioned
845 except that the epochs considered for the action locking were updated each
846 time according with the duration of the response.

847

848 **Clustering and decoding**

849 For clustering neurons based on their average responses around action onset
850 for both action-locking and runaway trials, we followed a similar general
851 procedure as in Namboodiri et al. 2019. Briefly, we first calculated the
852 average peri-event time histogram (PETH) for each neuron around each
853 action by averaging all trials. Due to the variability in reaction times from
854 looming stimulus onset until the action, we calculated the PETHs around a
855 time window from -0.5 s to +7s surrounding the action. This ensured that only
856 activity after the looming stimulus onset was included in all trials. The PETH
857 surrounding both action-locking and runaway trials were treated as features of
858 the response of a neuron. This feature space was then reduced in
859 dimensionality using principal components analysis (Fig S5). The number of
860 principal components to keep was decided based on the bend in the scree
861 plot (Namboodiri et al. 2019). A spectral clustering algorithm along with
862 optimal selection of number of clusters using silhouette scores (Namboodiri et
863 al. 2019) was used on the principal component scores to test for presence of
864 clusters. The number of clusters was chosen by maximizing the silhouette

865 score. Once cluster identities were assigned, all PETHs were recalculated
866 using the activity from -3 s to +7 s surrounding the actions. Only activity
867 following looming stimulus onset was included. If the looming stimulus onset
868 was less than 3 s prior to action on a trial, these data were treated as “not a
869 number (nan)” in our analysis pipeline.

870

871 We then tested for significant decoding by analyzing whether the activity of a
872 single neuron could be used to decode the chosen behavioral action on a trial.
873 To calculate a decoding accuracy, we trained a Naïve Bayes classifier on all
874 but one trial (leave-one-out cross-validation) and tested the decoding
875 accuracy on the remaining trial for each time epoch (Figure 4B). Within each
876 epoch, three “response features” were used for decoding analysis: slope of
877 the linear fit to fluorescence within the epoch, y-intercept of this fit, and lastly,
878 the standard deviation of fluorescence within the epoch (Figure 4B). Only
879 three features were used to avoid overfitting and maximize generalizability of
880 decoding on test trials. This procedure was repeated with each trial as the test
881 trial, to obtain an overall decoding accuracy above chance accuracy obtained
882 by shuffling trial identity. For the shuffled null, we calculated the mean chance
883 accuracy per neuron as the mean accuracy across ten different shuffles. We
884 applied this procedure to one neuron at a time to obtain a decoding accuracy
885 per neuron, which was then averaged across all neurons recorded, or all
886 neurons within a cluster. The decoding accuracy above chance was simply
887 calculated as the difference in population mean between the true accuracies
888 and the shuffled accuracies. Significance was tested based on a two-sample
889 t-test between the true accuracies and the shuffled accuracies.

890 **Statistical analysis.**

891 Offline analyses were performed using Prism 8 (Graphpad, US). Single data
892 points are always plotted. Sample size was pre-estimated from previously
893 published research and from pilot experiments performed in the laboratory.
894 Each mouse represents an analytical unit, for each experiment we stated the
895 replication factor. Compiled data are expressed as boxplots (median and
896 quartiles) or mean \pm S.E.M. Significance was set at $p < 0.05$ using two-sided
897 unpaired t-test, one or two-way ANOVA. Correlational analysis was performed
898 with Pearson test. Frequency distribution was analyzed with χ^2 test. The use
899 of the paired t-test and two way ANOVA for repeated measured were stated in
900 the legend figure text.
