23   **Abstract**

24   Changes in cell identities and positions underlie tissue development and disease progression.

25   Although, single-cell mRNA sequencing (scRNA-Seq) methods rapidly generate extensive lists of

26   cell-states, spatially resolved single-cell mapping presents a challenging task. We developed

27   SCRINSHOT (Single Cell Resolution IN Situ Hybridization On Tissues), a sensitive, multiplex

28   RNA mapping approach. Direct hybridization of padlock probes on mRNA is followed by

29   circularization with SplintR ligase and rolling circle amplification (RCA) of the hybridized padlock

30   probes. Sequential detection of RCA-products using fluorophore-labeled oligonucleotides profiles

31   thousands of cells in tissue sections. We evaluated SCRINSHOT specificity and sensitivity on

32   murine and human organs. SCRINSHOT quantification of marker gene expression shows high

33   correlation with published scRNA-Seq data over a broad range of gene expression levels. We

34   demonstrate the utility of SCRISHOT by mapping the locations of abundant and rare cell types

35   along the murine airways. The amenability, multiplexity and quantitative qualities of SCRINSHOT

36   facilitate single cell mRNA profiling of cell-state alterations in tissues under a variety of native and

37   experimental conditions.

45

46 **INTRODUCTION**

47 Recent advances in single-cell RNA sequencing technologies (scRNA-Seq) enabled

48 transcriptome analysis of individual cells and the identification of new cellular states in healthy

49 and diseased conditions (1). These methods however fail to capture the spatial cellular

50 organization in tissues due to cell dissociation. New spatial transcriptomic methods aim to

51 circumvent the problem of lost cellular topology (2). They can be divided into two categories: First,

52 targeted methods that directly detect specific mRNAs with single-cell resolution like ISS (3),

53 MERFISH (4), osmFISH (5) and second global methods, which are based on barcode annotated

54 positions and next generation sequencing to resolve RNA topology. The spatial resolution of

55 global methods is still larger than the typical cellular dimensions (6, 7).

56 Targeted methodologies are based on nucleic acid probes (mainly DNA), complementary to the

57 RNA species of interest, as in all *in situ* hybridization assays (8). Single-molecule fluorescence *in*

58 *situ* hybridization (smFISH) is the most powerful among the spatial transcriptomic methods and

59 has been used to supplement scRNA-Seq data with spatial information. It utilizes multiple

60 fluorophore-labeled probes, which recognize the same RNA molecule along its length and

61 visualize single RNA molecules as bright fluorescent dots (9, 10). Nonetheless, this method still

62 retains some limitations such as low signal-to-noise ratio, reduced sensitivity on short transcripts,

63 false positive signal due to unspecific-binding of the labeled probes and low capacity for multiplex

64 detection of many RNA molecules (11-13). Multiplex detection with smFISH was initially

65 addressed by the sequential fluorescence *in situ* hybridization (seqFISH) (14, 15) and the

66 multiplexed error-robust FISH (MERFISH) (4). These approaches utilize sequential rounds of

67 hybridization of FISH probes or barcode-based primary probes to detect multiple RNA species.

68 The outstanding throughput of these methods makes them strong candidates for generation of

69 spatial transcriptome maps in tissues. However, since the principle of these techniques is similar

70 to smFISH, they require large number of gene-specific probes, confocal or super-resolution

71   microscopy to deconvolve the signals and complicated algorithms for both probe design and

72   analysis. Nevertheless, the low signal-to-noise ratio still remains a major technical challenge of

73   these methods, especially for tissue sections with strong auto-fluorescence from structural

74   extracellular matrix components like collagen and elastin (16). New strategies for signal

75   amplifications, such as branched-DNA amplification (RNAScope) (17) and hybridization chain

76   reaction (18, 19), have been recently combined with sophisticated probe design (AmpFISH) (20)

77   to increase sensitivity and specificity of smFISH.

78   Padlock probes have been successfully used to detect RNA species (21). They are linear DNA

79   molecules, with complementary arms to the target mRNA sequence and a common "backbone".

80   Upon hybridization with the target sequence, they can be ligated, creating circular single-stranded

81   DNA molecules, which are used as templates for signal amplification using Φ29 polymerase-

82   mediated rolling circle amplification (RCA) (22). RCA products are large single stranded DNA

83   molecules containing hundreds of copies (23) of the complementary padlock-probe sequence.

84   They can be detected with fluorophore labelled oligos, which recognize either their RNA-specific

85   sequence or their backbone. Because each RCA-product contains hundreds of repeats of the

86   same detected sequence, the signal-to-noise ratio increases significantly, facilitating signal

87   detection by conventional epifluorescence microscopy. Also, multiplexity has been integrated into

88   the method by sequencing by ligation (24, 25). Since commercial ligases such as T4 DNA ligase,

89   T4 RNA ligase 2 and Ampligase show low activity on DNA/RNA hybrids, RNA has to be reverse-

90   transcribed to cDNA fragments before introducing padlock probes (3). However, cDNA synthesis

91   on fixed tissue sections is a challenging and expensive procedure (26), prompting new elegant

92   approaches trying to circumvent reverse-transcription by introducing Click-chemistry to ligate

93   DNA probes after hybridization on their RNA targets (ClampFISH (27)). More recently, "H-type"

94   DNA probes, which are hybridized to both RNA and padlock probes (PLISH (28)), or SNAIL-

95   design probes have been successfully used to facilitate intramolecular ligation of the padlock

96   probes (STARmap (25)).

97   PBVC-1 DNA ligase (also known as SplintR ligase) shows strong ligase activity of DNA

98   sequences in DNA/RNA hybrids. This enzyme is a DNA ligase encoded by *Paramecium bursaria*

99   *Chlorella* virus 1, first discovered by Ho et al.,(29). A number of studies have successfully applied

100   SplintR ligase for RNA species detection in cultured cells (26, 30-32). However, the fidelity of

101   SplintR ligation in end-joining is questionable because it tolerates mismatches at the padlock

102   probe junction and its usefulness is debated. In addition, SplintR ligase shows 1% of its ligation

103   activity on a 1-nucleotide gap of a nicked duplex DNA substrate (26, 33).

104   We present SCRINSHOT an optimized protocol for multiplex RNA *in situ* detection on

105   paraformaldehyde-fixed (PFA) tissue sections. We validated the sensitivity, specificity and

106   multiplexity of SCRINSHOT and showed that it is quantitative over a broad range of gene

107   expression levels. It is based on the *in situ* sequencing protocol (3) but bypasses the costly and

108   inefficient reverse transcription on fixed tissue to gain higher detection efficiency, by utilizing

109   SplintR ligase. To minimize false positive artifacts, we utilized 40nt long target-specific sequences

110   in the padlock probes in combination with stringent hybridization conditions. SCRINSHOT

111   performs on a variety of tissues including lung, kidney and heart and readily detects several

112   epithelial, endothelial and mesenchymal cells. We tested the multiplexing of SCRINSHOT on

113   mouse and human tissue sections, by simultaneous detection of characterized cell-type-selective

114   markers. SCRINSHOT successfully identified distinct cell-types and helped to create spatial maps

115   of large tissue areas at single cell resolution.

116 **RESULTS AND DISCUSSION**

117 **SCRINSHOT overview**

118 SCRINSHOT evolved from our attempts to improve the detection sensitivity and reduce the cost

119 of the *in situ* sequencing method, using PFA-fixed material. PFA fixation significantly improves

120 the histology but makes RNA less accessible to enzymes and padlock probes (24, 26). We

121 focused on stringent padlock probe hybridization to RNA targets and omitted the inefficient *in situ*

122 cDNA synthesis step (Figure 1 and Supplementary Figure 1). Gene-specific padlock probes are

123 first directly hybridized to 40nt long, unique sequences on the mRNA targets. Upon ligation of

124 bound padlock probes, we amplify the padlock probe sequence using Φ29 polymerase dependent

125 rolling cycle amplification. RCA products are subsequently detected by fluorophore-labelled oligos

126 which recognize the gene specific part of the padlock, as previously described (3). Multiplexity is

127 reduced compared to sequencing by ligation (24), which theoretically allows the detection of 256

128 transcript species in 4 hybridization runs, or to other barcode based approaches (4, 26). To

129 increase the number of detected genes we used sequential hybridization cycles of fluorophore-

130 labelled, uracil-containing oligos. After each detection cycle, fluorescent probes are removed by

131 enzymatic fragmentation by uracil-N-glycosylase (UNG) and stringent washes. Sequential

132 detection also enables the separate detection of low, medium and high abundant RNA species,

133 increasing the dynamic range of detection (34). Our detection probes were each labelled by one

134 of three commonly-used fluorophores and allowed up to 10 hybridization and imaging cycles,

135 typically detecting 30 genes. After image acquisition, we utilized manual segmentation of nuclei

136 and open access analysis tools for image stitching and signal quantification to construct a simple

137 pipeline for quantitative mapping of expression counts for 20-30 genes to thousands of cells on

138 tissue sections. The detailed protocol starting with tissue fixation and leading to mapping is

139 presented in the "Additional File 1".

140

SCRINSHOT specificity depends on stringent hybridization of the padlock probe

The specificity of SCRINSHOT crucially relies on the specific targeting of the SplintR ligation activity to the correct sites of the interrogated mRNA. A recent study (33) reported that the fidelity of this ligase is poor as it tolerates mismatches at padlock probe junctions. In addition, SplintR shows 1% of its ligation activity on a 1-nucleotide gap of a nicked duplex DNA substrate and it is unable to join ends across a 2-nucleotide gap (35). These results question the specificity of SplintR ligase-based methods for *in situ* RNA detection. We reasoned that the choice of padlocks with high melting points (Tm around 70°C) followed by stringent washes after DNA/RNA hybridization would circumvent SplintR promiscuity. We tested the dependence of SCRINSHOT signals on the hybridization and ligation steps of the padlock, by generating mutant padlocks, predicted to affect either the hybridization of the 3′padlock arm or the sequence of the ligation site. The 3′-scrambled arm of this padlock is expected to fail in hybridizing with the *Scgb1a1* mRNA, resulting in a linear, unligated padlock and therefore in a block in RCA. The single mismatch probe contains a single replaced nucleotide at the ligation site in 5′-end (C to G). This substitution was designed to address the effect of promiscuous ligation on the signal. In the same experiment, we included a slide, where we omitted the SplintR ligase from the reaction mixture to test whether padlock hybridization alone is sufficient to generate some RCA (SplintR[neg]; Figure 2 D, D′). In all tested conditions we also used the *Actb* normal padlock probe. This transcript was detected at similar levels in all slides and served as a control for the reactions with the mutated padlocks. We first counted the dots of *Scgb1a1* and *Actb* signals in all airway cells of sequential lung tissue sections and plotted their ratios at the different conditions (Figure 2). The signal from single-mismatch padlock probe was reduced by 20%, compared to the normal *Scgb1a1* probe demonstrating the low SplintR fidelity for the sequence of the ligation site (Figure 2 B, B′, E). The *Scgb1a1* signal was lost when we used the 3′-scrambled padlock, indicating that padlock probe hybridization is necessary for circularization and subsequent RCA (Figure 2 C, C′, E). The

166   omission of SplintR from the ligation mixture resulted in undetectable signal for both *Scgb1a1* and

167   *Actb* indicating the central role of ligation in signal amplification (Figure 2 D, D´, E). We noticed

168   that the *Scgb1a1* signal showed significant crowding and a potential saturation leading to

169   underestimation of the total number of RCA-products for this highly expressed gene (see below).

170   This crowding was evident even when we added 5-fold less *Scgb1a1* padlock probe (0.01 µM) to

171   the reactions in comparison to all other padlock probes. In an attempt to more accurately quantify

172   the differences between the signals from normal and mutated padlocks we measured the overall

173   fluorescence intensity (Raw Integrated Density) of the airway cell-ROIs. This showed that the

174   single mismatch at the ligation site of *Scgb1a1* padlock probe causes 3-fold fluorescence signal

175   reduction arguing that the *in situ* SplintR activity is substantially reduced, but not abolished by

176   single nucleotide substitutions at the ligation site (Figure 2F). We conclude that the specificity of

177   SCRINSHOT assay is largely provided by the hybridization stringency of the padlock probes,

178   since SplintR is unable to ligate off-target padlock probes, but can ligate single-mismatch probes

179   with low efficiency.

180

181   **A *Scgb1a1* antisense oligonucleotide competes with padlock probe hybridization and**

182   **signal detection**

183   If the padlock hybridization is the critical step for signal generation then competition by an

184   oligonucleotide, which recognizes the binding to the mRNA is expected to proportionally reduce

185   the detected RCA signal. We used the *Scgb1a1* and *Actb* padlocks together with increasing

186   concentrations of a competing, unlabeled oligonucleotide complementary to the mRNA sequence

187   recognized by the *Scgb1a1* padlock. Inclusion of the competitor reduced the *Scgb1a1* signal, in

188   a dose-dependent manner. Equal molar ratios of padlock probe and competitor caused signal

189   reduction by 10-fold and the signal was eliminated when 5-fold excess of the competitor was used

190   (Figure 3). This suggests that the SCRINSHOT signal is proportional to the target expression

191   levels because it can be proportionally competed with increasing concentrations of a synthetic

192   oligo masking the hybridization site. It also highlights the importance of proper padlock design to

193   achieve similarly high Tm values and hybridizations conditions for the different probes.

194

195   **Application of SCRINSHOT in other organs**

196   To evaluate SCRINSHOT applicability to other tissues, we performed the assay using PFA-fixed

197   sections from adult mouse kidney and heart and human embryonic lung. On murine tissues, we

198   used a common panel of padlocks targeting validated lung cell type markers. We targeted *Actb*

199   as a generic marker, *Pecam1* as an endothelial cell marker, *Scgb1a1* as a club cell marker, *Sftpc*

200   *and Napsa* as alveolar epithelial type II (AT2) cell markers and *Lyz2*, as a marker for AT2 cells,

201   macrophages and neutrophils (36). As expected, *Actb* was uniformly expressed in kidney and

202   heart while *Scgb1a1* and *Sftpc* were undetectable (Supplementary Figure 2 A, B). In both tissues,

203   *Lyz2* was expressed by a few scattered cells, which presumably correspond to macrophages (37,

204   38) (Supplementary Figure 2). In a subset of kidney tubular structures, we detected *Napsa*

205   (Supplementary Figure 2 A), which agrees with the previously described immunohistochemical

206   detection of the marker in renal proximal tubule cells (39). In the vessel walls of the heart, we

207   detected sparse signal for the endothelial cell marker *Pecam1* but the myocardial cells were

208   negative for the marker (Supplementary Figure 2 B). In the human embryonic lung sections, we

209   used probes targeting transcripts encoding 3 transcription factors, *SOX2*, *SOX9* and *ASCL1*

210   (Supplementary Figure 3), which have previously been detected by antibody staining in subsets

211   of epithelial cells (40, 41). In agreement with the published results, the SCRINSHOT signal for

212   *SOX2* was confined mainly in the proximal part of the branching epithelium, whereas *SOX9* was

213   selectively expressed in the distal tips. *ASCL1* expression overlapped with *SOX2* (Supplementary

214   Figure 3). These experiments show that SCRINSHOT can be readily applied to map cell-type

215   heterogeneity in a variety of tissues.

216

217 **SCRINSHOT generates quantitative gene expression profiles in single cells**

218 We first tested the quantitative power of SCRINSHOT by correlating its detection performance

219 with the fluorescence of a transgenic red fluorescent protein (RFP) in mouse lung tissue sections.

220 In the *Sftpc-CreER;Rosa-Ai14* reporter mouse, the RFP expression is activated in AT2 cells, upon

221 Tamoxifen induction of the Cre recombinase (42). Cre recombines out a

222 transcriptional/translational STOP cassette (43) of the Rosa26 locus and allows RFP protein

223 expression and fluorescence in AT2 cells (44). We injected pups with Tamoxifen on postnatal day

224 1 (P1) and analyzed the lungs on day P21. In the same experiment, we also used lungs from

225 *Sftpc-CreER*[neg]*-Rosa-Ai14*[pos] mice sacrificed at P21 and lungs from *wild type* mice sacrificed at

226 P60 as controls for the RFP induction and the potential effects of tissue autofluorescence in young

227 and fully developed lungs.

228 We first analyzed 14167 *Sftpc-CreER*[pos]*-Rosa-Ai14*[pos] cells and found a reliable correlation

229 (R^2=0.7233) between the endogenous RFP fluorescence and the SCRINSHOT-detected *RFP*

230 mRNA molecules in each cell (Figure 4 B). By contrast, there was no correlation between *RFP*

231 SCRINSHOT signal and the endogenous fluorescence (R^2=0.0671) in 3355 *Sftpc-CreER*[neg]-

232 *Rosa-Ai14*[pos] cells. As expected, in the 1008 analyzed *wild type* cells, the correlation of RFP

233 fluorescence and SCRINSHOT dots was very low. Upon closer inspection most of the signal in

234 this lung was due to high auto-fluorescence from red blood cells, illustrating the specificity of

235 SCRINSHOT (Figure 4 A, B).

236 Considering that the *Sftpc-CreER;Rosa-Ai14* reporter specifically labels the alveolar AT2 cells

237 (42), we used SCRINSHOT to identify the *Sftpc*[pos] AT2 cells and analyze their RFP expression in

238 both RNA (SCRINSHOT) and protein fluorescence (Raw Integrated Density) level (Figure 5 A, B,

239 D). In *Sftpc-CreER*[pos] cells the mean number of SCRINSHOT detected *RFP* mRNA molecules

240 was 6-fold higher compared to *Sftpc-CreER*[neg] cells. In the same comparison the RFP

241   endogenous fluorescence was 5-fold higher. In *wild type* cells, the SCRINSHOT *RFP* signal was

242   hardly detectable. We observed a slight increase in RFP fluorescence, in *wild type* cells compared

243   to the ones from the *Sftpc-CreER^{neg}* mouse, presumably due to different levels of tissue

244   autofluorescence depending on developmental stage and fixation time of the tissues (4 hours for

245   P21 *Sftpc-CreER* and 8 hours for *wild type* P60).

246   Apart from the AT2 cells, the lung alveolus contains additional cells types, including endothelial,

247   inflammatory, epithelial AT1 cells and fibroblasts (45). In the *Sftpc-CreER^{pos}-Rosa-Ai14^{pos}* lung,

248   AT2 cells should be both *RFP^{pos}* and *Sftpc^{pos}* whereas the rest should be *RFP^{neg}*. To evaluate the

249   specificity and sensitivity of SCRINSHOT in the strict context of a transgenic, knock-in marker

250   expression, we analyzed the *Sftpc* signal in *RFP^{pos}* and *RFP^{neg}* alveolar cells and the

251   SCRINSHOT *RFP* signal in *Sftpc^{pos}* and *Sftpc^{neg}* alveolar cells from the *Sftpc-CreER^{pos}-Rosa-*

252   *Ai14^{pos}* mouse. Both genes are highly expressed, therefore we applied a threshold of 3 dots/cell

253   to score a cell as positive (see also Supplement for details on setting detection thresholds). Of

254   the 1429 analyzed *RFP^{pos}* cells only 1.1% did not express *Sftpc* and were thus scored as false

255   negatives. Among the 6848 *RFP^{neg}* cells, 7.4% were positive for *Sftpc* and were considered as

256   false positives. Conversely, we failed to detect *RFP* signal in 4% of the 1679 analyzed Sftpc^{pos}

257   cells and counted them as false negatives. Among the Sftpc^{neg} cells 7% scored as positive for

258   SCRINSHOT *RFP* signal and were designated as false positives (Figure 5 C, D). Thus, the levels

259   of false positive and false negative cell annotations by SCRINSHOT are on average 5%. This is

260   likely an overestimate because Tamoxifen-induced recombination is rarely 100% efficient and

261   because leaky RFP transcripts from the *Rosa* locus may escape nonsense-mediated RNA decay

262   (NMD) (46). In conclusion, the analysis of the inducible knock-in reporter shows that the

263   SCRINSHOT *RFP* signal highly correlates with RFP endogenous fluorescence intensity in *Sftpc-*

264   *CreER^{pos}* AT2 cells only. The low levels of false positive and false negative SCRINSHOT signals

265   for *RFP* and *Sftpc* argue for the efficiency of SCRINSHOT in the identification and quantification

266   of gene expression in alveolar cell-types.

267

268   **Multiplex performance and gene expression quantification using SCRINSHOT**

269   To further explore the utility of SCRINSHOT in the spatial identification of cell types, we first tested

270   if multiple rounds of hybridization and detection in lung tissue sections lead to loss of detection

271   signal for the genes of interest, as seen in other transcriptomic approaches (5). We compared the

272   detection signals of *Calca*, a known neuroendocrine gene marker during the first and the eighth

273   cycles of hybridization and detection and found no significant loss of signal or decreased

274   specificity (Supplementary Figure 4). In the same experiment, we also detected a pair of marker

275   genes for airway secretory cells (*Scgb1a1* and *Cyp2f2*) and a pair of neuroendocrine cell markers

276   (*Ascl1* and *Calca*) and mapped them relatively to each other in the bronchiolar epithelium (Figure

277   6B). In total we analyzed 15 genes encoding soluble secreted proteins (*Scgb1a1*, *Napsa*, *Lgi3*,

278   *Calca*, *Sftpc* and *Lyz2*), cell surface proteins and receptors (*Cd74*, *Cldn18*, *Fgfr2* and *Ager*), a

279   metabolic enzyme *Cyp2f2*, and signaling proteins and transcription factors (*Axin2, Spry2*, and

280   *Etv5, Ascl1*) (Figure 6A, B). We first focused on *Sftpc-CreER*[pos]-*Rosa-Ai14*[pos] AT2 cells and on

281   the analysis of 11 selective AT2 markers covering a broad spectrum of expression levels (Figure

282   6 A, C). To evaluate the utility of SCRINSHOT in complementing scRNA-Seq data with spatial

283   information we compared the SCRISNSHOT analysis with available scRNA-Seq data from 156

284   AT2 cells (47). The mean values of SCRINSHOT dots in AT2 cells were proportional to the

285   scRNA-Seq raw count values of AT2 cells. Spearman correlation analysis showed a strong

286   correlation between the results of the two methodologies ($\rho=0.9455$) for highly-, moderately- and

287   lowly-expressed genes (Figure 6C). As expected, there was no correlation of the SCRINSHOT

288   data from 5615 *Sftpc*[neg] alveolar cells when we compared them to the AT2 scRNA-Seq dataset

289   ($\rho=0.1636$). The proportional mean gene expression levels in SCRISHOT and scRNA-Seq argue

290   that SCRINSHOT provides a suitable alternative for rapid, *in situ* evaluation of cell states detected

291   by scRNA-Seq.

292

293   **Spatial mapping of tracheal cell heterogeneity using SCRINSHOT**

294   Recently, two studies addressed the heterogeneity of tracheal epithelium using sc-RNA Seq.

295   These studies identified a new pulmonary cell type, which expresses *Cftr* and therefore

296   considered to play a role in cystic fibrosis pathophysiology (48, 49). They also provided the

297   detailed transcriptomic state of additional cell types, like basal, tuft and secretory cells, including

298   club and two classes of goblet cells.

299   We tested the ability of SCRINSHOT to detect the above cell types and analyze tracheal epithelial

300   cell heterogeneity with spatial, single-cell resolution. We used a panel of selective markers for

301   club, goblet, basal, tuft and ionocytes, as identified in (48, 49). The 29 analyzed genes included

302   (i) *Scgb1a1, Scgb3a1, Il13ra1, Reg3g, Lgr6* and *Bpifb1* as club-cell markers, (ii) *Foxq1, Gp2,*

303   *Pax9, Spdef, Tff2, Lipf, Dcpp3* and *Dcpp1* as goblet-cell markers, (iii) *Trp5, Il25, Gng13, Six1,*

304   *Alox5ap* and *Sox9* as tuft-cell markers, (iv) *Foxi1, Tfcp2l1, Cftr* and *Ascl3* as ionocyte markers,

305   (v) *Ascl1* as a neuroendocrine cell marker (50) and (vi) *Krt5, Pdpn* and *Trp63* as basal cell

306   markers. We also included *Muc5b* as a general secretory marker of the proximal airways (48, 49).

307   For assignment of cell positions we utilized structural landmarks that separate the tracheal airway

308   epithelium in three parts, the proximal, which extends until the end of the submucosal gland, the

309   intermediate part, which spans eight cartilage rings deeper and the distal, which includes the

310   remaining part of trachea epithelium, up to bronchial bifurcation (carina). We also assigned

311   positions to proximal intra-lobar airway epithelial cells, which extend up to the L.L3 branching

312   point (51) and to distal airway epithelial cells located at terminal bronchioles (Figure 7A).

313   For cell-type annotation, we initially applied the following threshold criteria for the selected marker

314   genes. We considered club cells, only the *Scgb1a1pos* cells, which were negative for the

315   neuroendocrine cell marker *Ascl1* and expressed up to one goblet, tuft, ionocyte and basal-cell

316   markers. *Ascl1pos* cells were considered as neuroendocrine cells. Similarly, we annotated the

317   analyzed cells as goblet, basal, tuft cells and ionocytes, if they were positive for at least two

318   characteristic genes of the respective type and only expressed up to one marker of the others.

319   The previously described similarities in gene expression between goblet and club cells in (48),

320   prompted us to consider a cell as goblet if it was positive for at least two of the identified goblet

321   cell markers, regardless of *Scgb1a1* expression. We sampled 1068 cells in submucosal glands

322   and 216 proximal trachea airway epithelial cells. In the intermediate part of the tracheal tube, we

323   quantified 953 cells and 1164 in the distal. In the intra-lobar airway epithelium, we analyzed 551

324   cells in proximal and 484 in distal airways. SCRINSHOT detected all the previously described

325   trachea cell-types. Club cells comprised 7% of total cells in proximal trachea and their proportion

326   gradually increased to 77% towards the distal intra-lobar airways (Figure 7B). *Trp63pos*, *Krt5pos*

327   and *Pdpnpos* basal cells were primarily detected in the intermediate part of the trachea (21% of

328   the measured cells) and became reduced towards the intra-lobar airways (Figure 7 B, C, D). Tuft

329   cells expressing *Trmp5*, *Gng13 and Alox* were exclusively found in the tracheal epithelium (Figure

330   7 B, C, E). Ionocytes present a rare cell-type (<1% of trachea epithelium) implicated in the

331   pathogenesis of cystic fibrosis. We detected sparse ionocytes expressing *Cftr* along with the

332   transcription factors *Tfp2l1*, *Ascl3* and *Foxi1* (48, 49) in the tracheal airway epithelium (Figure 7

333   B, F) and even more rarely in the submucosal glands (Supplementary Figure 6). Their restricted

334   positioning in the tracheal and submucosal gland epithelium highlights the importance of these

335   lung regions in cystic fibrosis caused by *Cftr* mutations in experimental models and in patients

336   (52, 53).

337   The majority of the *Ascl1*^pos NE-cells were detected in the proximal-trachea, but as expected we

338   also detected positive cells, scattered along the airways (Figure 7 B, C). Interestingly, 97% of the

339   goblet cells were detected in the submucosal gland but not airway epithelium (Figure 7 B, F). In

340   a hierarchical clustering of all annotated cells, the goblet cells were grouped together with the

341   Muc5b^pos cells into 2 clusters (Figure 7C). In agreement with the identification of 65 goblet cells

342   in the sc-RNA Seq data of Montoro et al. (48), *Gp2* is detected in the majority of goblet cells. We

343   also detected *Tff2*^pos *Muc5b*^pos cells corresponding the described *goblet-1* sub-cluster and cells

344   corresponding to the *Dcpp3*^pos *Lipf*^pos *goblet-2* sub-cluster. Interestingly, SCRINSHOT revealed

345   some additional spatial heterogeneity of *goblet-2* cells in the submucosal glands. We also noticed

346   Gp2^pospositive cells, expressing high levels of either *Dcpp3* or *Lipf* (Supplementary Figure 5 A)

347   and second, a small subset of the Dccp3^pos cells also expressed *Dcpp1* (Supplementary Figure 5

348   B, arrowhead) (48). The spatial analysis of epithelial cell types in the trachea and lung airways

349   demonstrate the utility of SCRINSHOT in the localization of rare cell types in a complex tissue.

350

351   **Spatial mapping of airway and alveolar cells**

352   We used the expression values of 15 genes, in 14167 cells, to generated a spatial map of

353   macrophages, AT1 and AT2 cells in the alveolar compartment and club and neuroendocrine cells

354   in the airways (Supplementary Figure 7). We annotated an airway cell as secretory if it was

355   *Scgb1a1*^pos *Cyp2f2*^pos *Ascl1*^neg and neuroendocrine if it expressed *Ascl1*. In the alveolar

356   compartment of the *Sftpc-CreER*^pos-*Rosa-Ai14*^pos lung, we annotated 1679 *Sftpc*^pos cells as AT2.

357   More than 99% of them also contained more than 3 dots of *Lyz2*, another AT2 marker (54), which

358   is also expressed by lung inflammatory cell-types (36, 55). 91.8% of the AT2 cells were also

359   scored positive for *Cd74*. This gene is significantly enriched in AT2 cells but it is also expressed

360   in hematopoietic lineages (56). Additionally, SCRINSHOT analysis distinguished a group of 588

361   *Lyz2*^pos *Cd74*^pos *Sftpc*^neg, which are probably macrophages. We also detected 312 cells positive

362   only for *Lyz2* and 450 expressing only *Cd74*. This suggests that the combinatorial expression of

363   3 genes defines four cell populations in the alveolar compartment, AT2 cells, *Lyz2*^{pos} *Cd74*^{pos}

364   macrophages and single *Lyz2*^{pos} or single *Cd74*^{pos} immune cells. For identification of AT1

365   epithelial cells, we used the expression of *Ager* (57). We scored 1129 alveolar *Ager*^{pos} *Sftpc*^{neg}

366   *Scgb1a1*^{neg} cells as AT1. This analysis argues that SCRINSHOT can readily distinguish known

367   epithelial cell types in the lung airways and alveoli. Additional markers for other characterized cell-

368   types, such as endothelial cells and fibroblasts, could be also included in future analyses to

369   facilitate the creation of complete spatial maps of cells types in various organs and help to

370   elucidate gene-expression and cell-type distribution patterns in healthy and diseased tissues.

371

372   **CONCLUSION**

373   SCRINSHOT simplifies multiplex, *in situ* detection of RNA in various tissues. The assay is

374   optimized for high sensitivity and specificity. We present a robust analysis protocol with minimal

375   requirements for extensive instrumentation or computational skills, which makes it user-friendly

376   and accessible in many fields of biology. The protocol is suitable for validation of scRNA-seq

377   results in small- or large-scale experiments or for the analysis of gene expression changes upon

378   genetic or chemical manipulations. Importantly, SCRINSHOT is also a low-cost method compared

379   to other *in situ* hybridization methods or antibody detection and the straight forward analysis

380   protocol makes it suitable for routine laboratory use. Although SCRINSHOT multiplexity is

381   reduced compared to "*in situ* sequencing" by ligation (24) or other barcode-based approaches (4,

382   58), the number of detection fluorophores or hybridization detection cycles can be increased to

383   detect 50 genes per slide. Manual cell segmentation is the most time-consuming part of the

384   analysis and we believe that automatic segmentation will provide a future solution. At present, our

385   attempts with open access programs like Ilastik (59) or Cell Profiler (60) only scored a 50%

386   success rate in segmentation of lung sections presumably because of the elongated and

387   overlapping cell shapes and the large cavities of the lung alveolar compartment. Confocal

388   microscopy and higher magnifications may improve resolution but cost will also increase. The

389   SCRINSHOT analysis of the mouse submucosal gland, trachea and proximal-lung airway

390   epithelium for 29 genes and distal-lung for the expression of 15 genes demonstrates the capacity

391   of the method to detect not only low abundance mRNAs but also rare cell-types, like ionocytes,

392   tuft and neuroendocrine cells, facilitating the generation of cellular maps from complex tissues.

393

394   **MATERIALS AND METHODS**

395   **Animals and Histology**

396   All experiments with *wild type* (C57Bl/6J) mice were approved by the Northen Stockholm Animal

397   Ethics Committee (Ethical Permit numbers N254/2014, N91/2016 and N92/2016).

398   For transgenic mouse experiments, *Sftpc-CreER*negative(42);*Rosa26-Ai14*positive(44) and *Sftpc-*

399   *CreER*negative;*Rosa26-Ai14*positive individuals were used according to German regulation for animal

400   welfare at the Justus Liebig University of Giessen (Ethical Permit number GI 20/10, Nr. G

401   21/2017). The recombination and *Sftpc*pos cell labelling of the *Sftpc-CreER*pos;*Rosa26-Ai14*pos lung

402   was done by one subcutaneous injection of Taxamoxifen, on postnatal day 1 (P1) and the tissues

403   were collected on P21. An *Sftpc-CreER*neg;*Rosa26-Ai14*pos littermate treated as above and used

404   as negative control, in addition to a *wild type* P60 lung.

405   For lung tissue collection, the mice were anesthetized with a lethal dose of ketamine/xylazine.

406   Lungs were perfused with ice cold PBS 1X pH7.4, through the heart right ventricle to remove red

407   blood cells from the organ. A mixture (2:1 v/v) of (PFA 4% (Merck, 104005) in PBS 1X pH7.4):OCT

408   (Leica Surgipath, FSC22) was injected into the lung, from the trachea using an insulin syringe

409   with 20-24G plastic catheter B Braun 4251130-01), until the tip of the accessory lobe got inflated

410   and the trachea was tied with surgical silk (Vömel, 14739). The lungs were removed and placed

411   in PFA 4% in PBS 1X pH7.4 for 4 hours for P21 lungs and 8 hours for adult, at 4°C in the dark,

412   with gentle rotation or shaking. The other analyzed organs were simply placed in PFA 4% in PBS

413   1X pH7.4 for 8 hours.

414   The tissues were transferred to a new tube with a mixture (2:1 v/v) of (30% sucrose in PBS 1X

415   pH7.4):OCT at 4°C for 12-16 hours, with gentle rotation or shaking. Thereafter, tissues were

416   embedded in OCT (Leica Surgipath, FSC22), using specific molds (Leica Surgipath, 3803025)

417   and frozen in a slurry of isopentane and dry ice. Tissue-OCT blocks were kept at -80°C until

418   sectioning. 10 µm thick sections were cut with a cryostat (Leica CM3050S) and placed on poly-

419   lysine slides (Thermo, J2800AMNZ), kept at room temperature for 3 hours with silica gel (Merck,

420   101969) and then stored at -80°C for further use.

421

Embryonic human lungs

423   Use of human fetal material from elective routine abortions was approved by the Swedish National

424   Board of Health and Welfare and the analysis using this material were approved by the Swedish

425   Ethical Review Authority (2018/769-31). After the clinical staff acquired informed written consent

426   by the patient, the tissue retrieved was transferred to the research prenatal material lung sample

427   was retrieved from a fetus at 8.5 w post-conception. The lung tissue was fixed for 8 hours at 4°C

428   and processed as above.

429

Probe Design

431   A detailed description of the Padlock probe design is provided in the Additional File 1. Briefly, the

432   PrimerQuest online tool (Integrated DNA Technologies: IDT) was used to select sequences of

433   Taqman probes (40-45 nucleotides) for the targeted mRNA. These sequences were then

434   interrogated against targeted-organism genome and transcriptome, with Blastn tool (NLM) to

435 guarantee their specificity. The Padlock Design Assistant.xlsm file was used to split the

436 sequences in two and integrate them into the padlock backbone. Padlock probes were ordered

437 from IDT as Ultramer DNA oligos and their sequences are provided in Additional File 2.

438 The 40-45 Taqman probe sequences were also used to prepare the fluorophore-labelled oligos.

439 Using the IDT OligoAnalyzer tool the length of the sequences was adjusted to Tm 56°C. To

440 remove the fluorescent oligos after each detection cycle, we exchanged "T" nucleotides with "U"

441 and treated with Uracil-DNA Glycosylase (Thermo, EN0362). Detection oligos were labelled at

442 their 3'-end with fluorophores and manufactured by Eurofins Genomics. The sequences of

443 fluorophore-labelled oligos are provided in Additional File 3.

444

445 **Pretreatments of the slides**

446 Slides were transferred from -80°C to 45°C to reduce moisture. A post fixation step with 4% PFA

447 in PBS 1x pH7.4 was done, followed by washes with PBS-Tween20 0.05%. Permeabilization of

448 tissues was done with 0.1M HCl for 3 minutes, followed by two washes with PBS-Tween20 0.05%

449 and dehydration with a series of ethanol. SecureSeal™ hybridization chambers (Grace Bio-Labs)

450 were mounted on the slides and sections were preconditioned for 30 minutes at room temperature

451 (R/T) with hybridization-reaction mixture of 1X Ampligase Buffer (Lucigen, A1905B), 0.05M KCl

452 (Sigma-Aldrich, 60142), 20% deionized Formamide (Sigma-Aldrich, F9037), 0.2µg/ul BSA (New

453 England Biolabs, B9000S), 1U/µl Ribolock (Thermo, EO0384) and 0.2µg/µl tRNA (Ambion,

454 AM7119). To block unspecific binding of DNA we included 0.1µM Oligo-dT30 VN.

455

456 **Padlock probe hybridization, ligation and RCA**

457 Hybridization of the Padlock probes was done in the above solution, omitting Oligo-dT30 VN and

458 adding 0.05 µM of each Padlock probe. We used three padlock probes for every targeted RNA-

459 species. For the highly abundant *Scgb1a1* mRNA, we used 0.01 µM of one padlock probe to

460 minimize molecular and optical saturation. Hybridization included a denaturation step at 55°C for

461 15 min and an annealing step at 45°C for 2 hours. Not hybridized padlock probes were removed

462 by washes with 10% Formamide in 2X SSC (Sigma-Aldrich, S6639). To minimize the effect of

463 the previously documented SplintR ligase nucleotide preferences (26, 33), padlock probe ligation

464 was performed overnight O/N at 25°C using the SplintR ligase (NEB, M0375) at a final

465 concentration of 0.5 Units/µl, T4 RNA ligase buffer (NEB, B0216) and 10µM ATP, according to

466 manufacturer recommendations (see New England Biolabs webpage).

467 Rolling Cycle Amplification (RCA) was done O/N at 30°C using 0.5 Units/µl Φ29 polymerase

468 (Lucigen, 30221-2). The reaction mixture contained also 1X Φ29 buffer, 5% Glycerol, 0.25 mM

469 dNTPs (Thermo, R0193), 0.2 µg/µl BSA and 0.1 µM RCA primers (RCA Primer1:

470 TAAATAGACGCAGTCAGT*A*A and RCA Primer2: CGCAAGATATACG*T*C). The "*" indicate

471 Thiophosphate-modified bounds to inhibit the 3-5 exonuclease activity of Φ29 polymerase (23).

472 A fixation step with 4% PFA for 15 minutes was done to ensure stabilization of the RCA-products

473 on the tissue. Sections were thoroughly washed with PBS-Tween20 0.05% before next step.

474

Hybridization of detection-oligos

476 The visualization of the RCA products was done with hybridization of the 3'-fluorophore labeled

477 detection oligos. The reaction mixture contained 2X SSC, 20% deionized Formamide, 0.2 µg/µl

478 BSA, 0.5 ng/µl DAPI (Biolegend, 422801), 0.4 µM FITC-labeled and 0.2 µM Cy3- and Cy5-labeled

479 detection probes for 1 hour at R/T. Washes were performed with 10% Formamide in 2X SSC,

480 followed by 6X SSC. Tissues sections were dehydrated with a series of ethanol, chambers were

481 removed and the slides were covered with SlowFade™ Gold Antifade Mountant (Thermo,

482 S36936) and a coverslip.

483   After image acquisition, the coverslips were removed by placing the slides in 70% ethanol in 45°C.

484   Then, sections were dehydrated using a series of ethanol to mount the hybridization chambers.

485   After tissue rehydration with PBS-Tween20 0.05%, the detection-oligos were digested with Uracil-

486   DNA Glycosylase for 1hour at 37°C. The reaction mixture contained 1X UNG buffer, 0.2 µg/µl

487   BSA and 0.02 Units/µl Uracil-DNA Glycosylase (Thermo, EN0362). Destabilized oligos were

488   stripped off by thorough washes with 65% deionized Formamide at 30°C. Multiple rounds of

489   hybridization and imaging, as described above, were performed until all genes were imaged.

490

491   **Image acquisition**

492   Images were captured with a Zeiss Axio Observer Z.2 fluorescent microscope with a Colibri led

493   light source, equipped with a Zeiss AxioCam 506 Mono digital camera and an automated stage,

494   set to detect the same regions after every hybridization cycle.

495

496   **Image analysis**

497   The nuclear staining was used to align the images of the same areas between the hybridizations

498   and multi-channel *.czi files, containing the images of all genes, were created using Zen2.5 (Carl

499   Zeiss Microscopy GmbH). The images were analyzed as 16bit *.tiff files, without compression or

500   scaling. Images were tiled using a custom script in Matlab (The MathWorks, Inc.). Manual nuclear

501   segmentation was done with Fiji ROI Manager (61). The nuclear ROIs were expanded for 2 µm

502   with a custom Cell-Profiler script and considered as cells. The signal-dots were counted in these

503   cell-ROIs using Cell-Profiler 3.15 (60), Fiji (62, 63) and R-RStudio (58, 64-67) custom scripts

504   (https://github.com/AlexSount/SCRINSHOT).

505

506   **Thresholding**

507 A cell-ROI size criterion was applied to remove the outliers with very small or big surface. In

508 particular, only cells included between two standard deviations of the mean size of the analyzed

509 cells were further processed. In SCRINSHOT we considered a cell-ROI positive for an analyzed

510 gene, we used a threshold strategy. First, we determined the maximum numbers of signal-dots

511 per cell-ROI for all analyzed genes. A cell-ROI was considered as positive, if it contained more

512 than 10% of the maximum number of signal-dots for the specific gene. The higher threshold was

513 set to 3, which was applied for highly abundant genes with maxima over 31 signal dots.

514

Curation of the data

516 In general, the 2 μm nuclear expansion provides an underestimation of real signal dots and

517 provides satisfactory results for airway cells (e.g. Figure 3A' merge-images with cell-ROI outlines)

518 but the cellular segmentation of the alveolar region is more challenging mainly because of the

519 irregular cell shapes and their overlap. This gave false positive cell-ROIs due to dots from adjacent

520 true-positive cells being erroneously assigned to their neighbors. To reduce the noise, signal-dots

521 of highly abundant RNA-species were used to visually inspect and remove the problematic cell-

522 ROIs from further analysis.

523

Clustering

525 Annotated cells of submucosal gland, trachea and lung airway epithelium were clustered using

526 hclust package in R (68). Log_2(dots/cell + 1) values were used to calculate Euclidean distances

527 and clustering was done using ward.D2 method. Balloon plots were created by ggpubr package

528 in R (69) and heatmaps with pheatmap package (70). Bootstrapping analysis was done by the

529 clusterboot package (71). Clusters were considered as "stable" if bootstrap values were >0.5.

530

531 **Analysis of *Sftpc-CreER*^pos^;*Rosa26-Ai14*^pos^ cells**

532 For the identification of the RFP^pos^ alveolar cell-ROIs in the *Sftpc-CreER*^pos^;*Rosa26-Ai14*^pos^ lung,

533 all analyzed alveolar cells from the RFP^neg^ *Sftpc-CreER*^neg^;*Rosa26-Ai14*^pos^ lung were used to

534 determine the maximum endogenous fluorescence (in Raw Integrated Density values) and set it

535 as a threshold. The RFP^pos^ and RFP^neg^ cell-ROIs were curated and the *Sftpc* signal-dots were

536 measured in them.

537 For the correlation of RFP endogenous fluorescence with SCRINSHOT *RFP* signal, the

538 endogenous fluorescence (in Raw Integrated Density values) of all segmented cell-ROIs from the

539 analyzed tissue sections was correlated with the detected RFP signal-dots in the same cell-ROIs,

540 using simple linear regression analysis in Graphpad Prism with default settings.

541

542 **Comparison of SplintR and cDNA-based detection of RNA species**

543 To compare the performance of padlock-probe hybridization (i) directly on RNA (SCRINSHOT)

544 and (ii) after cDNA synthesis, we used sequential 10μm-thick sections from adult mouse lungs,

545 fixed for 8 hours (see above). cDNA-based approaches in earlier publications have only used

546 fresh frozen tissues and pepsin or proteinase K tissue treatments to increase RNA accessibility

547 (3, 24). The padlock probes were designed to recognize exactly the same sequence of the

548 analyzed genes. For the highly (*Scgb1a1, Sftpc*) and intermediate (*Actb*) expressed genes, we

549 used only one padlock probe and for *Pecam1*, three probes because of its lower expression

550 levels.

551 For cDNA synthesis, the RNA species of the tissue sections were transformed to cDNA by reverse

552 transcription (RT) using random decamers. The RNA strands were degraded with RNaseH to let

553 padlock probes hybridize to the corresponding cDNA sequences. Padlock probe ligation was

554   done with Ampligase DNA ligase. All other steps were done according to the provided

555   SCRINSHOT protocol.

556   For cDNA synthesis we used 20 U/µl of the SuperScript™ II Reverse Transcriptase (Thermo,

557   18064014), 1X SuperScript™ II RT buffer (Thermo), 0.5 mM dNTPs (Thermo, R0193), 10mers-

558   random primer (Thermo), 0.2 µg/µl BSA (NEB, B9000S), and 1 U/µl RiboLock RNase Inhibitor

559   (Thermo, EO0384), at 42°C, O/N. The slides were post-fixed with 4% (w/v) PFA in PBS 1X pH7.4,

560   at RT for 30 min, following by 6 washes with PBS-Tween 0.05%.

561

562   **Evaluation of SCRINSHOT specificity using mutated padlock probes**

563   The experiment was done as described above, using 0.01 µM of *Scgb1a1* padlock probes and

564   0.05 µM of the *Actb*. The "mismatch" probe had the same sequence as the normal *Scgb1a1*

565   padlock probe with a C>G substitution at the 5'- ligation site and the "3'-scrambled" probe had the

566   same 5'-arm but the 3'-arm was scrambled. *Actb* padlock probe was used as internal control to

567   calculate the *Scgb1a1/Actb* ratios. The *Scgb1a1/Actb* ratios of cell-ROIs with zero *Actb* signal-

568   dots were considered as zeros. The detection of all *Scgb1a1* RCA-products was done using a

569   detection oligo, which recognizes the padlock-backbone of *Scgb1a1* but not of *Actb*. *Actb* RCA-

570   product was detected by a detection oligo, which recognizes its gene-specific sequence

571   (Additional File 3). The *Scgb1a1/Actb* fluorescence ratios were calculated using the Raw

572   Integrated Densities of the two genes in each cell-ROI.

573

574   **Evaluation of SCRINSHOT specificity using an antisense competitor**

575   To compete the binding of Scgb1a1 padlock probe on its target transcript, an antisense competitor

576   (A), which recognizes the Scgb1a1 mRNA between nucleotides 316-378 and masks the padlock

577   probe hybridization site, was used in the same hybridization mixture with the *Scgb1a1* padlock

578   probe (P) at different ratios: (i) P:A=1:0, (ii) P:A=1:1, (iii) P:A=1:5, keeping the *Scgb1a1* padlock

579   probe concentration to 0.05μM.

580

581   **Correlation with SCRINSHOT with published single cell RNA sequencing datasets**

582   The GSE118891 dataset was used to retrieve gene expression values (raw counts) of all AT2,

583   according to the cell annotation of provided metadata file (47). The genes of interest were selected

584   and their Mean values were calculated and log_2(dots+1) transformed. Similarly, the SCRINSHOT

585   signal-dots per cell-ROI were log_2(dots+1) transformed. Pearson correlation analysis was done

586   using GraphPad Prism.

587

588   **Statistical analysis**

589   All statistical analyses were done with Graphpad Prism, using nonparametric tests, since the

590   SCRINSHOT data do not follow canonical distributions. Multiple comparisons were done using

591   ANOVA Kruskal-Wallis multiple comparison test, without multiple comparison correction ("*": P ≤

592   0.05, "**": P ≤ 0.01, "***": P ≤ 0.001, "****": P ≤ 0.0001). For pairwise comparisons the statistical

593   analysis was done using Mann-Whitney nonparametric t-test ("*": P ≤ 0.05, "**": P ≤ 0.01, "***": P

594   ≤ 0.001, "****": P ≤ 0.0001). Spearman correlation was used to examine the correlation between

595   SCRINSHOT and scRNA-Seq data.

596

597   **Availability of data and materials**

598   The datasets and analysis files of the current study have been deposited at Zenodo repository

599   (DOI: 10.5281/zenodo.3634561).   All   scripts   are   available   at

600   https://github.com/AlexSount/SCRINSHOT.

601

Author contributions

603 CS and AS conceived the idea and designed the experiments with help by MN and WS. ABF and

604 AF provided mouse tissues and ES the human fetal material. AS and HPN performed all

605 hybridizations. AS, AL and XQ wrote the analysis scripts. AS, AL and ABF analyzed the datasets.

606 All authors helped interpreting results. CS, AS and HPN wrote the manuscript and AS the detailed

607 protocol (Additional file 1) with input from all other authors. All authors read and approved the final

608 manuscript. CS provided all funding support.

609

Acknowledgments

611 We would like to thank the Associate Professor Qi Dai for the thorough reading and suggestions

612 of the detailed SCRINSHOT protocol (Additional File 1).

613

Funding

615 This study was supported by grants from the Swedish Research Council (Vetenskapsrådet, 2016-

616 05059) and the Swedish Cancer Society (Cancerfonden, 160499) to CS.

617

Competing interests

619 MN and XQ hold shares in CARTANA AB, a company that commercializes *in situ* sequencing

620 technology.

621

622

623   **Figure Legends**

624   **Figure 1.** Schematic representation of SCRINSHOT. The major steps of the assay are (A) All

625   padlock-probe hybridization for all the targeted RNA-species followed by ligation and RCA-

626   amplification. (B) RCA-products are detected sequentially reading three per cycle, with FITC-,

627   Cy3- and Cy5- labelled detection-oligos, which recognize the gene-specific part of the padlock

628   probes. (C) Images from all detection cycles are aligned using DAPI nuclear staining and

629   segmented to create the cell-ROIs and signal-dots are counted and registered to the cell-ROIs.

630

631   **Figure 2.** SCRINSHOT specificity relies on stringent hybridization of padlock probes to their target

632   RNAs. Images of SCRINSHOT signal, using normal *Scgb1a1* padlock probe (A), a *Scgb1a1*

633   padlock probe with a point mutation at its ligation site (B), a *Scgb1a1* padlock probe with 3'-

634   scrambled arm (C) and normal padlock probe but omitting SplintR ligase (D). *Actb* normal padlock

635   probe was used in all conditions as internal control. DAPI: blue, *Scgb1a1*: gray, *Actb*: red. "n"

636   indicates the number of airway cells in the corresponding images. (A'-D') Magnified areas of the

637   indicated positions (square brackets) of images in the left. Pink outlines show the 2 μm expanded

638   airway nuclear ROIs, which are considered as cells. Scale-bar: 150 μm. (E) Violin plot of the

639   Scgb1a1 and Actb signal-dots ratio in all airway cells. The ratio of cells with zero *Actb*-dots

640   considered as zero. (F) Violin plot of the *Scgb1a1* and *Actb* fluorescence intensity ratio in all

641   airway cells. SplintR[pos] n=473, mismatch n=574, 3´-scrambled n=507 and SplintR[neg] n=488.

642

643   **Figure 3.** Concentration-dependent SCRINSHOT detection efficiency. (A-C) Representative

644   images of SCRINSHOT signals for *Scgb1a1* padlock probes in the absence or presence of an

645   antisense competitor oligo targeting the binding site of *Scgb1a1* padlock probe. SCRINSHOT

646   signal for *Scgb1a1* padlock probe in the absence of the antisense competitor oligo (A), when

647 mixed in equal concentration with the antisense competitor oligo (B) and when mixed with five

648 times higher concentration of the antisense competitor oligo (C). (A'-C') Magnified areas of the

649 indicated positions (square brackets) of images A-C. (D) Violin plot of the *Scgb1a1* and *Actb*

650 signal-dots ratio in all airway cells of the three compared conditions. P: padlock probe, A:

651 antisense competitor. Scale bars in (A-C) is 100 µm and (A'-C') is 10µm. All analyses were done

652 using raw images and the same thresholds. For visualization purposes, brightness and contrast

653 of *Scgb1a1* were set independently in the compared conditions to show the existence of signal in

654 the presence antisense competitor and avoid signal saturation in its absence.

655

656 **Figure 4.** Efficient detection of *Rosa-Ai14* mRNA upon *Sftpc-CreER* driven recombination, using

657 SCRINSHOT. (A) Representative images of alveolar regions from P21 *Sftpc-CreER*^{pos};*Rosa-*

658 *Ai14*^{pos}, P21 *Sftpc-CreER*^{neg};*Rosa-Ai14*^{pos} and P60 wild-type (*Sftpc-CreER*^{neg};*Rosa-Ai14*^{neg}) lung

659 sections. Asterisks indicate red blood cells with high auto-fluorescence, which give some false

660 positive signals in wild-type lung, only. DAPI: blue, *RFP* mRNA detected with SCRINSHOT:

661 magenta and endogenous fluorescence of RFP: green. Scale-bar: 10µm. (B) Regression

662 analyses of RFP endogenous fluorescence (RAW integrated density) and *Ai14* SCRINSHOT

663 dots, in the three analyzed lung sections, using Graphpad Prism. "n" indicates the number of total

664 cells in the analyzed images, which used for the statistical analysis.

665

666 **Figure 5.** Correlation of *Sftpc* SCRINSHOT dots with RFP endogenous fluorescence and *RFP*

667 mRNA signals. (A) Images of alveolar compartment from P21 *Sftpc-CreER*^{pos};*Rosa-Ai14*^{pos}, P21

668 *Sftpc-CreER*^{neg};*Rosa-Ai14*^{pos} and P60 wild-type (*Sftpc-CreER*^{neg};*Rosa-Ai14*^{neg}) lung sections,

669 showing *Sftpc*^{pos} (gray) AT2 cells in correlation to *Ai14* SCRINSHOT dots (detected *RFP* mRNA)

670 (green) and RFP endogenous fluorescence (red). Scale-bar: 10 µm. "n" designates the number

671 of analyzed AT2 cells. (B) Violin plots of SCRINSHOT results for *RFP*, in addition to RFP

672   endogenous fluorescence (RAW integrated density) in AT2 cells of the analyzed lungs. (E) Bar

673   plots of SCRINSHOT results for *Sftpc* in RFP^{pos} and RFP^{neg} alveolar cells, as indicated by

674   endogenous fluorescence of *Sftpc-CreER^{neg};Rosa-Ai14^{pos}* alveolar cells (threshold 2304340 units

675   of raw integrated density), in addition to RFP in *Sftpc^{pos}* and *Sftpc^{neg}* AT2 cells. Threshold is set

676   to 3 dots and shown with red dotted lines.

677

678   **Figure 6.** SCRINSHOT multiplexity and correlation with single-cell mRNA sequencing. (A)

679   Representative image of an alveolar region (Alv), showing the SCRINSHOT signal-dots of 11 AT2

680   selective genes. Merge image includes *Ager* (gray), *Sftpc* (green), *Cd74* (magenta) and DAPI

681   (blue) for nuclear staining. The rest of the genes are indicated with italics and only single-channel

682   images were used. (B) Image of an airway region (arw) with a neuroepithelial body (NEB),

683   containing SCRINSHOT dots for the club-cell markers *Scgb1a1* (green) and *Cyp2f2* (yellow) and

684   neuroendocrine (NE)-cell markers *Calca* (magenta) and *Ascl1* (gray). DAPI (blue) used for

685   nuclear staining. (C) Correlation plot of the indicated genes, between the $\log_2$(raw counts+1)

686   values of 156 AT2 cells from Liu et al., 2019 and SCRINSHOT signal dots of 1679 AT2 cells.

687   Scale bar: 10μm.

688

689   **Figure 7.** Spatial mapping of tracheal cell types with SCRINSHOT. (A) Overview of analyzed

690   trachea and lung tissue sections using nuclear staining. Analyzed areas are indicated by brackets,

691   corresponding to proximal trachea, submucosal glands (GS), intermediate and distal trachea,

692   followed by proximal and distal lung airways. Trachea image includes also thyroid glands. Scale

693   bar: 500μm. (B) Balloon plot of the annotated cell-types at the analyzed positions. The balloon

694   size indicates the percentage of the cell-type at the indicated position relatively to the total number

695   of cells of the cell-type. The balloon intensity corresponds to the percentage of the specified cell-

696   type, relative of the total number of cells at the indicated position. (C) Hierarchical clustering of

697   the annotated cells. Heatmap shows the $\log_2$(dots/cell + 1) gene values in the analyzed cells. (D)

698   Characteristic example of basal cells in tracheal epithelium. *Trp63* (green), *Ktr5* (red), *Pdpn* (gray)

699   and DAPI (blue). Scale bar: 10µm. (E) Detection of a tuft cell in tracheal epithelium. *Sox9* (green),

700   *Gng13* (red), *Alox5ap* (gray), *Trpm5* (yellow), *Six1* (magenta) and DAPI (blue). Scale bar: 10µm.

701   (F) An ionocyte in trachea airway epithelium, detected with *Tfcp2l1* (green), *Foxi1* (red), *Cftr*

702   (gray), *Ascl3* (yellow) and Dapi (blue). Scale bar: 10µm.

703

704   **Supplementary Figure 1.** Comparison of SplintR-based (SCRINSHOT) and the cDNA-based *in*

705   *situ* hybridization assays for high, intermediate and low abundant genes in sequential PFA fixed

706   lung sections. (A) Images of SplintR-based (SCRINSHOT) and cDNA-based *in situ* hybridization

707   assays, in sequential lung sections. DAPI: blue, *Scgb1a1*: green, *Sftpc*: gray, *Actb*: red and

708   *Pecam1*: cyan. Pink outlines show the 2 µm expanded airway nuclear ROIs, which are considered

709   as cells. The square brackets indicate the magnified areas on the right. The "n" correspond to the

710   number of counted cells in large images. Scale bar: 100µm. (B) Bar-plots of the analyzed gene

711   signals, in the indicated tissue compartments, for SCRINSHOT and cDNA-based approaches.

712   The differences between the two conditions are significant ($P < 0.0001$) for all analyzed genes.

713   (C) Histograms of the analyzed genes. The Y-axes indicate the percentage of the cell-ROIs and

714   the X-axes, the binned signal dots in each cell. In SplintR-condition, 350 cells localized in airways

715   (arw) and 1624 in alveolar (alv) compartment. In cDNA-condition, there are 295 airway and 1706

716   alveolar cells. Analysis was done using raw images, with the same acquisition conditions and

717   thresholds. Only for visualization purposes, signal intensity of *Scgb1a1* and *Sftpc* in cDNA-

718   condition was set 5-times higher than SplintR.

719

720   **Supplementary Figure 2.** SCRINSHOT application on mouse kidney and heart. (A) Application

721   of SCRINSHOT in adult mouse kidney sections shows signal for *Actb* (gray), *Napsa* (magenta)

722   and *Lyz2* (cyan) but not *Scgb1a1* (green) and *Sftpc* (red). (B) Representative image from an adult

723   mouse heart section, containing a vessel (v). *Pecam1* (magenta) is detected at the vessel walls,

724   *Actb* (gray) is uniformly expressed and *Lyz2* (cyan) labels a few cells (presumably macrophages)

725   but not *Scgb1a1* (green) and *Sftpc* (red) are not detected. DAPI: blue, scale bar: 50µm.

726

727   **Supplementary Figure 3.** SCRINSHOT application on fetal human lung. On the left, overview of

728   a w8.5 whole left lung tissue section, showing SCRINSHOT signal for *SOX2* (green), *SOX9* (red)

729   and *ASCL1* (gray). The square brackets correspond to the images on the right. DAPI (blue) was

730   used as nuclear staining. Scale bar: 500µm. (A) Representative image of proximal epithelium,

731   which is highly positive of *SOX2* and *ASCL1* but not *SOX9*. (B) Representative image of highly

732   *SOX9* positive distal epithelium.

733

734   **Supplementary Figure 4.** Comparison of detected *Calca* RCA-products in first and eighth

735   hybridizations. (A, B) Images on the left show the *Ascl1*^{pos} (gray) neuroendocrine cells of an airway

736   neuroepithelial body, in relation to *Scgb1a1*^{pos} (red) club cells. DAPI: blue, scale bar: 10µm. (C)

737   Note that neuroepithelial bodies are tightly packed cellular structures, as indicated by DAPI

738   nuclear staining. The images on the right show the *Calca* RCA-products, detected in the first (D)

739   and the eighth (E) detection cycles. (D'-F') Magnified areas of the indicated positions (brackets)

740   of images D-F, respectively. (F) Overlay of *Calca* identified signal-dots in first (cyan) and eighth

741   (yellow) detection cycles, using the same threshold in CellProfiler.

742

743   **Supplementary Figure 5.** SCRINSHOT mapping of submucosal glands reveals spatial

744   heterogeneity in goblet cell population. Overview of the analyzed submucosal gland for the

745   expression of 6 goblet cell markers shows their expression in submucosal gland but not airway

746   epithelium. *Muc5b* is detected along the airway epithelium of the proximal trachea, indicating that

747   it is a general proximal epithelial cell marker. *Tff2*: green, *Muc5b*: red, *Gp2*: gray, *Dcpp3*: cyan,

748   *Dcpp1*: magenta, *Lipf*: yellow, DAPI: blue and cell-ROIs: pink. Scale bar: 500µm. (A) Insert

749   showing the previously described *Muc5b^{pos} Tff2^{pos}* goblet subtype (arrow) and the *Lipf^{pos} Dcpp3^{pos}*

750   (asterisk). *Lipf^{pos} (hash)* and *Dcpp3^{pos}* (arrowhead) are detected in the same region, being positive

751   for the general goblet cell marker *Gp2*. (B) Insert showing regionally restricted expression of

752   *Dcpp1* in a subset of *Dcpp3^{pos}* cells. Insert scale bar: 10µm.

753

754   **Supplementary Figure 6.** Ionocyte in the submucosal gland. (Top) overview of the analyzed

755   submucosal gland, showing SCRINSHOT signal for ionocyte markers, *Tfcp2l1* (green), *Cftr*

756   (gray), *Foxi1* (red), *Ascl3* (yellow) and DAPI (blue). Scale bar: 500µm. (Bottom) Magnified area of

757   the indicated square in overview image, showing a detected ionocyte in submucosal gland. Scale

758   bar: 10µm.

759

760   **Supplementary Figure 7.** SCRINSHOT generates cell-type digital annotation maps of large

761   tissue areas. (i) Overview image of SCRINSHOT fluorescence signal-dots for *Scgb1a1* (green),

762   *Sftpc* (magenta) and *Ascl1* (gray) of a large area from P21 *Sftpc-CreER^{pos};Rosa-Ai14^{pos}* lung

763   section, after Tamoxifen induction on P1 (RFP was not shown at that image). The image contains

764   14167 manual segmented nuclei, which were expanded for 2 µm and considered as cells. (ii)

765   Spatial map of annotated cell types according to the indicated criteria. (A) Same airway area as

766   in Figure 6B, showing club (*Scgb1a1*: green and *Cyp2f2*: yellow) and NE-cell (*Calca*: magenta

767   and *Ascl1*: gray) markers, in an airway position with a neuro-epithelial body (NEB). (A') Cell-type

768   digital annotation of the area corresponding to "A". The "*" indicate *Ascl1^{pos} Calca^{neg}* cells Club

769   cells: green and NE-cells: red. (B) Same alveolar area as in Figure 6A showing *Ager^{pos}* (gray)

770   *Sftpc^{neg}* (green) *Cd74^{neg}* (magenta) AT1 cells (arrow), *Ager^{low} Sftpc^{pos} Cd74^{low}* AT2 cells (asterisks)

771   and $Ager^{neg}$ $Sftpc^{neg}$ $Lyz2^{pos}$ $Cd74^{high}$ macrophages (mΦ, arrowhead). (B') Cell-type digital

772   annotation of the area corresponding to "B". AT1 cells: gray, AT2 cells: magenta and

773   macrophages: white. All not annotated cells are depicted with blue. Scale bar: 200μm.
