Introduction

In the past decade, new diagnostic methods and strategies have appeared, HIV testing efforts and the generalization of antiretroviral therapy may have influenced the number of opportunistic diagnoses and mortality of HIV-infected patients. To test this hypothesis we compiled data on the top opportunistic infections and causes of early death in the HIV cohort of French Guiana.

Methods

HIV-infected persons followed in Cayenne, Kourou, and Saint Laurent du Maroni hospitals from 2010 to 2019 were studied. The annual incidence of different opportunistic infections and annual deaths were compiled. For patients with opportunistic infections we calculated the proportion of early deaths.

Results

At the time of analysis, among 2 459 patients, (treated and untreated) 90% had a viral load <400 copies, 91% of the patients in the cohort were on antiretroviral treatment, and 94.2% of patients on treatment for over 6 months had undetectable viral loads. Only 9% of patients had CD4 counts under 200 per mm3. Disseminated histoplasmosis clearly remained the most frequent (128 cases) opportunistic infection among HIV-infected persons followed by cerebral toxoplasmosis (63 cases) and esophageal candidiasis (41 cases). Cryptococcal meningitis was ranked 5th most frequent opportunistic infection as was tuberculosis (31 cases). The trend for a sharp decline in early deaths continued (3.9% of patients).
Conclusions

Despite the successes of antiretrovirals, patients presenting with advanced HIV are still common and they are still at risk of dying. Improved diagnosis, and notably systematic screening with appropriate tools are still important areas of potential progress.

Key words: AIDS; histoplasmosis; cryptococcosis; tuberculosis; advanced HIV; Latin America

Author summary

In the past decade, new diagnostic methods and strategies have appeared, HIV testing efforts and the generalization of antiretroviral therapy may have influenced the number of opportunistic diagnoses and mortality of HIV-infected patients. To test this hypothesis we compiled data on the top opportunistic infections and causes of early death in the HIV cohort of French Guiana. HIV-infected persons followed in Cayenne, Kourou, and Saint Laurent du Maroni hospitals from 2010 to 2019 were studied. The annual number of different opportunistic infections and annual deaths were compiled. For patients with opportunistic infections we calculated the proportion of early deaths. At the time of analysis, most patients were virologically controlled and had restored immunity. However, histoplasmosis clearly remained the most frequent (128 cases) opportunistic infection among HIV-infected persons followed by cerebral toxoplasmosis (63 cases) and esophageal candidiasis (41 cases). Cryptococcal meningitis was ranked 5th most frequent opportunistic infection as was tuberculosis (31 cases). The trend for a sharp decline in early deaths continued (3.9% of patients). Despite the successes of antiretroviral therapy, patients presenting with advanced HIV are still common and they are still at risk of dying. Improved diagnosis, and notably systematic screening with appropriate tools are still important areas of potential progress.
Introduction

Nearly a decade ago we showed that the top ranking HIV-related opportunistic infectious diseases in French Guiana, a French territory in South America, were quite different from what is usually described in Europe.[1] Indeed, as immunosuppression grows, the respective frequency of AIDS-defining infections reflects the regional pathogen ecosystem. A good knowledge of the local epidemiology is therefore crucial to guide the clinicians’ diagnostic hypotheses, their investigations and urgent therapeutic decisions. In the past decade, knowledge and awareness of regional particularities have evolved and new diagnostic methods and strategies have appeared.[2,3] HIV testing efforts may have reduced the size of the reservoir of undiagnosed HIV infections, and the generalization of antiretroviral therapy has decreased HIV incidence and improved the overall immunity of HIV cohorts.[4,5] Such evolution is likely to influence the number of diagnoses and mortality of HIV-infected patients.[6] To test this hypothesis we compiled data on the top opportunistic infections and causes of early death (1 month after an opportunistic infection) in the HIV cohort of French Guiana.

Methods

The standards of healthcare in French Guiana are similar to those of metropolitan France.[7] All human immunodeficiency virus (HIV) patients receive free antiretroviral treatments (usually the most recent drugs) regardless of their residence status or income. Medical imagery, viral loads, CD4 counts, genotyping, antiretroviral concentration measurements, a rich diagnostic arsenal are available for routine care. The parasitology-mycology laboratory performs fungal culture, and Pasteur institute performs tuberculosis diagnoses (direct examination, PCR, and culture). The diagnosis of histoplasmosis relies on the identification of histoplasma on direct examination of samples, culture, or histopathology. Antigen testing is not available for routine care in French Guiana.

HIV-infected persons followed in Cayenne, Kourou, and Saint Laurent du Maroni hospitals between January 1, 2010 and December 31, 2019 were enrolled in the French Hospital Database for HIV (FHDH). The database includes most patients followed in French Guiana and nearly all AIDS cases. Trained technicians entered the demographic data, diagnoses, treatments, medical events, viral loads, CD4 and CD8 counts. Annual incidence of different opportunistic infections and annual deaths are compiled. For patients with opportunistic infections we calculated the proportion of early deaths (<1 month after diagnosis).

Patients included in the FHDH give informed consent for the use of their anonymized data and for the publication of anonymized results. This data collection has been approved by the Commission Nationale Informatique et Libertés (CNIL) since 1992 and the cohort has led to several international publications. The data were analyzed with R.

Results

On December 31st 2019, there were 2 459 patients in the active HIV cohort. Between 2012 and 2019 there was an average 5.5% annual increase of the cohort size. The sex ratio is 0.99 except in Western French Guiana where it was female-biased (0.62). The age group distribution was: <15 years (1.5%), 15-39 years (34%), 40-59 years (46%), and 60+ (18.5%). Overall, 33% of patients were born in Haiti (mostly in Cayenne), 18% in Suriname (Mostly in Saint Laurent du Maroni), 14% in France, 10% in Brazil, 8% in Guyana, for 12 % the information was not available, and for the remaining 5 % in a variety of countries. Among the
total cohort, (treated and untreated) 90% had a viral load <400 copies, 91% of the patients in
the cohort (1 749/1 921, 108 treatment naive, and 64 interruptions) were on antiretroviral
treatment, and 94.2% of patients on treatment for over 6 months had undetectable viral loads
(up from 78% in 2012). At the time of analysis, only 9% of patients had CD4 counts under
200 per mm3.

Figure 1 Shows the Ranking of the most frequent incident AIDS-defining infections in French
Guiana between 2012 and 2019. Histoplasmosis clearly remained the most frequent
opportunistic infection among HIV-infected persons followed by cerebral toxoplasmosis and
esophageal candidiasis. Pneumocystosis which often ranks higher in mainland France was
ranked 4th and was followed by cryptococcal meningitis and tuberculosis (Fig 1).

**Fig 1. Most Frequent opportunistic infections in French Guiana 2012-2019**

Fig. 2 shows the historical evolution of disseminated histoplasmosis diagnoses and the sharp
decline in early deaths (<1 month after diagnosis of histoplasmosis).

**Fig 2. Evolution of Histoplasmosis and deaths<1 month**

**Discussion**

The present results show that, despite a very high proportion of the cohort on virologically
successful antiretroviral treatment, disseminated histoplasmosis remained the most frequent
opportunistic infection. The case fatalities within 1-month of diagnosis, a time-frame used to
reduce the likelihood of other causes of death,[6] has further decreased showing that
awareness, aggressive investigations, and presumptive treatment with efficacious antifungal
drugs and antiretrovirals[8] leads to good outcomes in most patients with disseminated
histoplasmosis. Since our previous analysis of the main opportunistic infections[1], the
implementation of systematic screening for cryptococcal antigen using the CrAg LFA may
explain why cryptococcosis went from the 8th most frequent to the 5th most frequent
opportunistic infection, a feature that surely distinguishes French Guiana from mainland
France. On the contrary wasting syndromes were the 4th AIDS defining event before 1996,
then the 6th AIDS defining event in 1996-2008 and drop to the 8th position during the past
decade. This suggests that improved diagnoses, and notably systematic screening with
appropriate tools allowed progress in the identification of opportunistic agents, notably
cryptococcus.

With the arrival of new Histoplasma antigen detection methods,[9–11] the possibility of
screening for histoplasma, analogous to screening for cryptococcus[3], raises a new and
important research question: should we screen all patients with less than 200 CD4 for
histoplasmosis? Primary prophylaxis is in practice rarely implemented perhaps because of the
fear of drug-drug interactions, antifungal resistance selection, and because physicians often
expect that antiretroviral therapy will quickly restore immunity. With progress, opportunistic
infections seem not so much a priority as before, and diagnosis of opportunistic infections is
no longer a specific topic in French HIV expert recommendations. However, despite the
successes of antiretrovirals, patients presenting with advanced infections are still not rare and
even today they are still at risk of dying.[12] So for French Guiana, access to commercial
histoplasma antigen detection test is important if we wish to further reduce severe forms of
disseminated histoplasmosis, and detect the disease in its early stages of dissemination when
its clinical presentation is not yet fully patent. For other countries, where awareness and
mycological expertise is not present, where liposomal amphotericin is absent, the added value would be even greater.[13–15] This is in total alignment with the Manaus declaration in 2019 recommending access to diagnostic tests and effective treatment for all hospitals in Latin America by 2025, further emphasized by the imminent WHO/PAHO guidelines for the diagnosis and treatment of disseminated histoplasmosis in HIV patients.[16]
