Highlights

- Thottea siliquosa is a traditional Ayurvedic medicine
- T. siliquosa exhibits significant anti-inflammatory and anticancer properties
- Polyphenolic compounds may be responsible for the bioactivities of T. siliquosa
- T. siliquosa may be a source for novel bioactive components
Abstract

**Background and Aim:** Oxidative stress and inflammation are the predominant cause of chronic diseases including cancers, thereby making it as an essential target for preventing these disorders. Various natural products and plants have been shown to prevent the process of free radical induced damages. The present study evaluated the biological properties of *Thottea siliquosa*, belonging to the family Aristolochiaceae, which is a traditionally used Ayurvedic plant.

**Experimental Procedure:** Antioxidant assays carried out were DPPH, FRAP, hydrogen peroxide scavenging and hemolysis inhibition assay; nitric oxide and lipoxygenase inhibition assays were used for anti-inflammatory studies. Anticancer activity was done using human endometrial and breast cancer cells by MTT assay.

**Results and Conclusion:** The results of the present study showed antioxidant properties for the methanolic crude extract of *T. siliquosa* as DPPH radical scavenging (110.40±4.5 µg/mL), FRAP capacity (41.1±6.2), peroxide scavenging (233.4±14.2 µg/mL) etc. In addition, anti-inflammatory properties are also evident in terms of nitric oxide radical scavenging (28.76±3.9 µg/mL) and lipoxygenase inhibition (39.2±3.2 µg/mL) assays. Further, the anticancer activity of these extract has been identified against human endometrial and breast cancer cells. Further studies together with a bioassay guided fractionation may identify possible bioactive compounds.

**Keywords:** *Thottea siliquosa*; antioxidant activity; anti-inflammatory activity; anticancer activity; polyphenols
1. Introduction

Inflammation is the primary protective response of the body against exogenous molecules/organisms. This involves a cascade of events which involve the recruitment of inflammatory cells to the site of action, release of inflammatory mediators from the granules of cells and subsequent tissue damage and edema. Acute inflammation is often described as protective response, as it doesn’t damage tissues for a long time. On the other hand, chronic inflammation, which lasts for a longer period of time are reported to be deleterious to the body.

Numerous studies have described the association of chronic inflammation with the onset and progression of various diseases such as cancers, cardiovascular diseases, fatty liver, and Alzheimer’s disease. Several studies have indicated that use of non-steroidal anti-inflammatory drugs can reduce the incidence of various cancers, cardiovascular diseases, acute respiratory problems, and Alzheimer’s disease. Thus, inflammatory molecules have become the primary target for the prevention of various diseases.

Natural products has always been the source of drugs, likewise several different anti-inflammatory drugs have been isolated from the Mother Nature. In addition, the search for new anti-inflammatory drugs is also been intensified due to its multi-targeted nature and lack of side effects. Aristolochiaceae is an important family which is well known for its antioxidant and anticancer compound Aristolochic acids (AAs). The pharmacological properties of the family include anti-diarrhoeal, anticancer, anti-inflammatory and antipruritic activity. Several novel alkaloid and terpenoids have also been isolated from the different plants belonging to this family. The plants belonging to this family are also used traditionally in Chinese and Ayurvedic medicines as well as different folklore medicinal systems. Thottea siliquosa is an unexplored medicinal plant which is traditionally used for...
digestive tract disorders and inflammatory conditions. Very limited literature is available on
the biological and pharmacological properties of the plant. The only available published
research indicates that the leaf and root extracts of \textit{T. siliquosa} exhibits antibacterial activity
against Streptococcus, \textit{E. coli} and \textit{Pseudomonas} strains \footnote{Authors note}. Apart from these there are no
available reports on the antioxidant and anti-inflammatory activities of the plant. Thus, the
present study aimed to evaluate the antioxidant, anti-inflammatory and anticancer activities of
the plant and further to elucidate the mechanism of action of the same.

2. Materials and Methods

2.1 Collection of plant material and extraction

The leaves of \textit{Thottea siliquosa} plant was collected from Western Ghats regions of Kerala.
The whole plant was cleaned properly, shade dried, and coarsely powdered. The powdered
materials (10 g) were extracted with methanol (100 mL) by Soxhlet apparatus and the
extracts obtained were concentrated under reduced pressure at 40°C using rotary evaporator.
A portion of the residue was dissolved at 10 mg/mL stock solution in Dimethyl sulfoxide
(DMSO) for the study and remaining portion was stored at 4°C for further use.

2.2 Cell lines and maintenance

Cells (HeLa and MCF7) were procured from National Centre for Cell Science, Pune and
maintained at 5% carbon dioxide at 95% humidity. The cells were cultured in RPMI-1640 or
DMEM media supplemented with 10% foetal bovine serum. The cells was passaged every
third day or before reaching 80% confluency.

2.3 Total phenolic and total flavonoids content
Total phenolic content was quantified using a modified Folin-Ciocalteu method. The results were compared to the standard curves and expressed as mg Gallic acid equivalent per gram dry powder for the samples.

Total flavonoid contents was quantified using the method explained by Khodaie, Bamdad, Delazar, Nazemiyeh and the results were expressed as mg quercetin equivalent per gram dry powder for the samples.

2.4 In vitro antioxidant activities

In vitro antioxidant capacity of the extract was determined in terms of DPPH radical scavenging, Ferric reducing antioxidant power (FRAP), and hydrogen peroxide scavenging potentials.

2.5 In vitro anti-inflammatory activity

Lipoxygenase is an important mediator of inflammation, thereby making it a target for anti-inflammatory activity. Inhibition of 5-Lipoxygenase was assessed according to the previously described methods. Likewise nitric oxide scavenging activity had also been carried out as an indicator of anti-inflammatory potential. Percentage inhibition was calculated and IC\textsubscript{50} was determined as per the methods described by Kakatum, Jaiarree, Makchucit, Itharat.

2.6 Anti-hemolytic potential

The anti-hemolytic activity induced by a peroxyl radical initiator, AAPH was measured according to the method established by Salini, Divya, Chubicka, Meera, Fulzele, Ragavamenon, Babu. Two hundred microliters of blood were mixed with 10 μL of plant extract at various concentrations (0-100 μg/mL) and then 600 μL of AAPH (10%) was added. The mixture was incubated at 37\textdegree C for 30 minutes and the absorbance of the mixture was
measured at 450 nm. The protective effect of the extract was expressed as the half maximum percentage inhibition of hemolysis induced by AAPH.

2.7 Anticancer activity

Cells were obtained from National Centre for Cell Sciences, Pune, India. They were maintained in RPMI-1640/ DMEM media, supplemented with 10% FBS at 37 °C and 5% CO₂. To study the anticancer activity, cancer cells (2.5x10⁵ / 250 µL volume) was plated in 48-well culture plates and was allowed to grow to subconfluency. Cells were then treated for 48 h with different concentrations of the plant extract (1 - 200 µg/mL). The percentage cell viability of each was determined thereafter using determined using 3-(4,5- dimethyl thiazol-2-yl)-2, 5-diphenyl tetrazolium bromide- MTT assay.

2.8 Statistical analysis

The values of in vitro studies were represented as mean± SD of four individual sets of the experiment, each conducted in triplicate. Statistical analysis was carried out by one way ANOVA followed by Tukey-Kramer multiple comparison tests using Graph Pad Prism software 7.0 versions.

3. Results

3.1 Total phenols and flavonoids content

The total phenol content of Methanolic extract of T. siliquosa was 4.67±0.41 GAE/ g of dry leaf. The flavonoid content of the extract was 1.88±0.22 QE/ g dry leaf (Figure 1).

3.2 In vitro antioxidant and anti-inflammatory potential

Antioxidant potential of the Thottea siliquosa methanolic extract has been evaluated in terms of DPPH radial scavenging, hydrogen peroxide radical scavenging, ferric reducing
antioxidant power etc. The IC$_{50}$ value of the extract in the DPPH scavenging was 110.40±4.5; the half maximum inhibition value for hydrogen peroxide scavenging was 233.4± 14.2 µg/mL. The EC$_{50}$ value in FRAP assay was found to be 41.1± 6.2 µg/mL (Table 1).

The plant exhibited anti-inflammatory potential in lipoxygenase inhibition assay and nitric oxide scavenging. The IC$_{50}$ values for the lipoxygenase inhibition and and nitric oxide scavenging assay were found to be 39.2± 3.2 and 28.76± 3.9 µg/mL (Table 1).

3.3 Anti-hemolytic potential and lipid peroxidation inhibition in RBC

As shown in Table 1, the IC$_{50}$ values of hemolysis by T. siliquosa treatment were 47.2±2.2 µg/mL. Morphological analysis also supported these results (Figure 2), where increased membrane damage caused by AAPH derived peroxyl radical was restored by the treatment with T. siliquosa extract. The lipid peroxidation in RBC was determined in terms of the TBARS, which was found to be 2.68±0.47 nmoles/mg Hb in untreated RBC, which was elevated to 7.12±0.62 nmoles/mg Hb in AAPH alone treated cells. TBARS level was reduced to 4.77±0.35 and 5.68±0.39 nmoles/mg Hb in cells pre-treated with T. siliquosa extracts (50 and 25 µg/mL).

3.4 In vitro anticancer activity

The anticancer potential of the extract was evaluated against HeLa (human endometrial cancer) and MCF7 (Human breast cancer) cells using MTT assay. The drug showed dose dependent decrease in the cell viability over a period of 48 hours and the IC$_{50}$ value for the MCF7 cells was found to be 76.12± 5.5 µg/mL; the value was found to be 115.71± 10.2 µg/mL in HeLa cells (Figure 3).

Discussion
Oxidative stress and inflammation are the two predominant driving forces behind various degenerative diseases. Hence, prevention of oxidative insults and chronic inflammation is the primary step for the prevention of these disorders. The present study analyzed the antioxidant and anti-inflammatory properties of a traditionally used Ayurvedic medicinal plant, Thottea siliquosa. Results show the moderate antioxidant properties of the plant in terms of DPPH and hydrogen peroxide radical scavenging properties and ferric reducing capacity. In addition to these, the extract also showed significant anti-inflammatory properties as indicated by the nitric oxide radical scavenging and lipoxygenase inhibition potential. By comparing the IC50 values for various antioxidant and anti-inflammatory assays, it can be assumed that the plant possess a high anti-inflammatory property than an antioxidant nature. The results also show that T. siliquosa efficiently reduces the damages induced by AAPH mediated oxidative toxicity, thereby improving the cell viability in human RBC.

Hydrogen peroxide and AAPH are significant sources of free radical generators, which are experimentally used to represent oxidative stress condition in cells. Among these, hydrogen peroxide derived radicals are the most potent in the induction of toxicity in mammalian cells. Azo compounds including AAPH are initiators of alkoxy and peroxyl radicals in the hydrophilic compartments. Under physiological temperature, AAPH reduces automatically to form peroxyl radical (ROO•)27,28. Unlike the H2O2 radicals, alkoxy and peroxyl radicals cannot pass through the cell membrane; whereas they react with the membrane leading to the peroxidation of membrane lipids29 and lipid peroxidation mediated oxidative DNA damages30. According to the reports by Sato, Kamo, Takahashi, Suzuki31, irrespective of the polar nature of AAPH, the generated peroxyl radicals diffuses through the lipid bilayer and be vested in in the nonpolar hydrocarbon interior. This increase the susceptibility of the cells to peroxidative changes, as hydrophobic region contains a considerably higher amounts of polyunsaturated fatty acids. This results in the initiation of a cascade of peroxidative events in
the RBC membrane and thereby leading to hemolysis. Corroborating with these reports, the present study also observed a significant reduction in the AAPH induced lipid peroxidation in RBC membrane. It is thus possible that the observed reduction in lipid peroxidation products in RBCs pre-treated with T. siliquosa may be the mechanism of antihemolytic properties of the plant.

Apart from these, the extract also showed significant anticancer properties against human endometrial and breast cancer cells. It is expected that the dose dependent anticancer properties may be mediated through apoptotic changes, however, further studies are necessary to ascertain these facts. The study also observed the presence of high amount of polyphenols and flavonoids in the T. siliquosa extract, which might be responsible for the protective effects observed against free radicals and anti-inflammatory potential. In addition, these bioactive polyphenol compounds are also known for their anticancer potentials. It is therefore expected that further purification of the extract may be helpful to identify novel bioactive compounds with antioxidant, anti-inflammatory and anticancer properties.
