

L1CAM is not Associated with Extracellular Vesicles in Human Cerebrospinal Fluid or Plasma

Supplementary Information

Supplementary Figure 1: Linearity of dilution for Simoa assays

Supplementary Table 1: Spike and recovery for Simoa assays

Supplementary Figure 2: Comparison of ELISA and Simoa for EV quantification

Supplementary Figure 3: Mass spectrometry of L1CAM immunocaptured from plasma

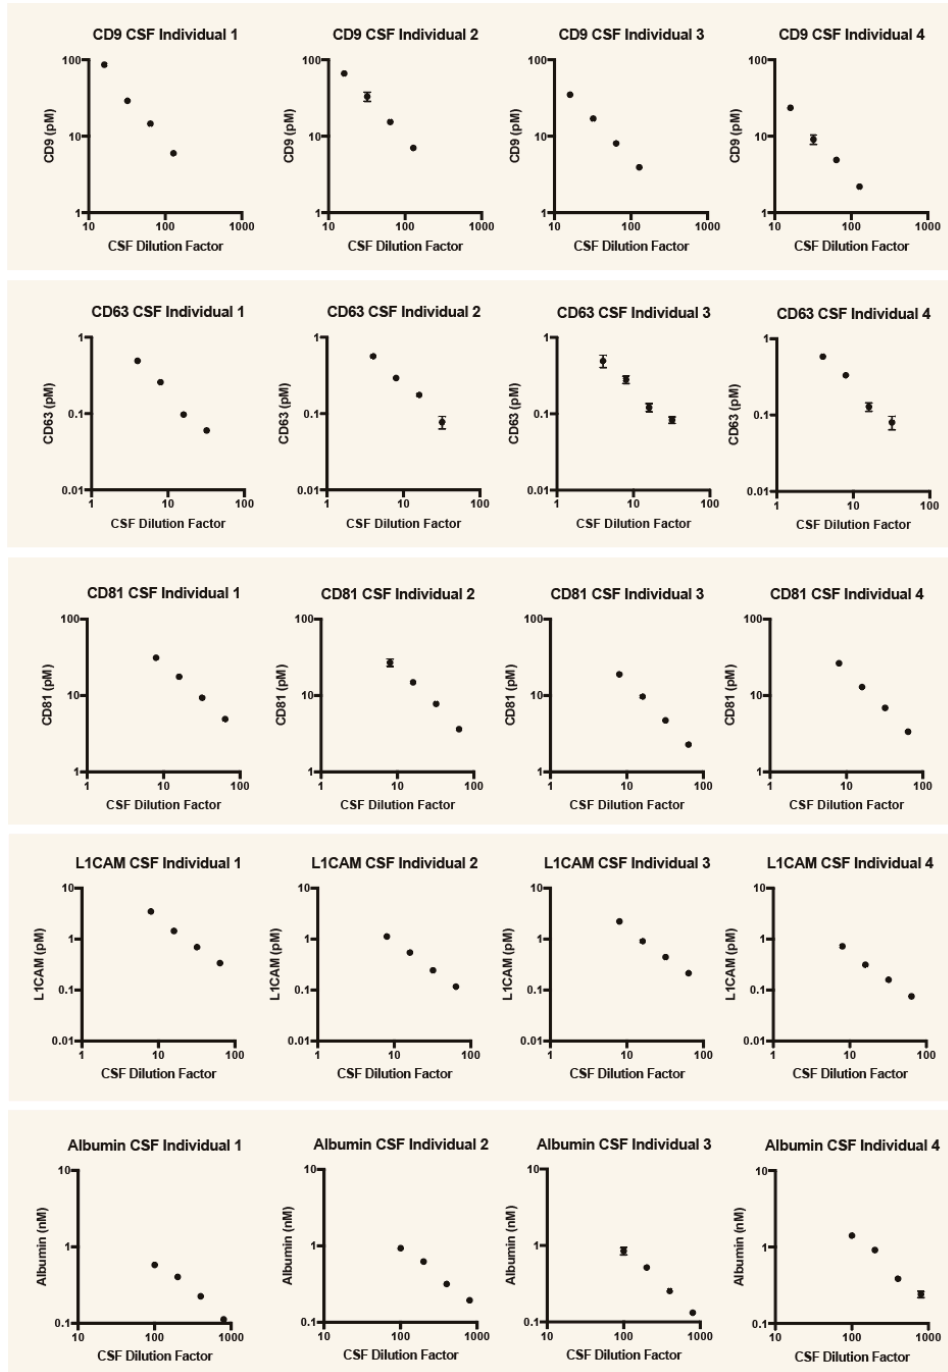

Supplementary Figure 4: Analysis of reads from GTEx RNA-Seq Data indicating Exon 25 skipping in alternative splicing of L1CAM

Supplementary Figure 5: Affinity of L1CAM for recombinant alpha-synuclein

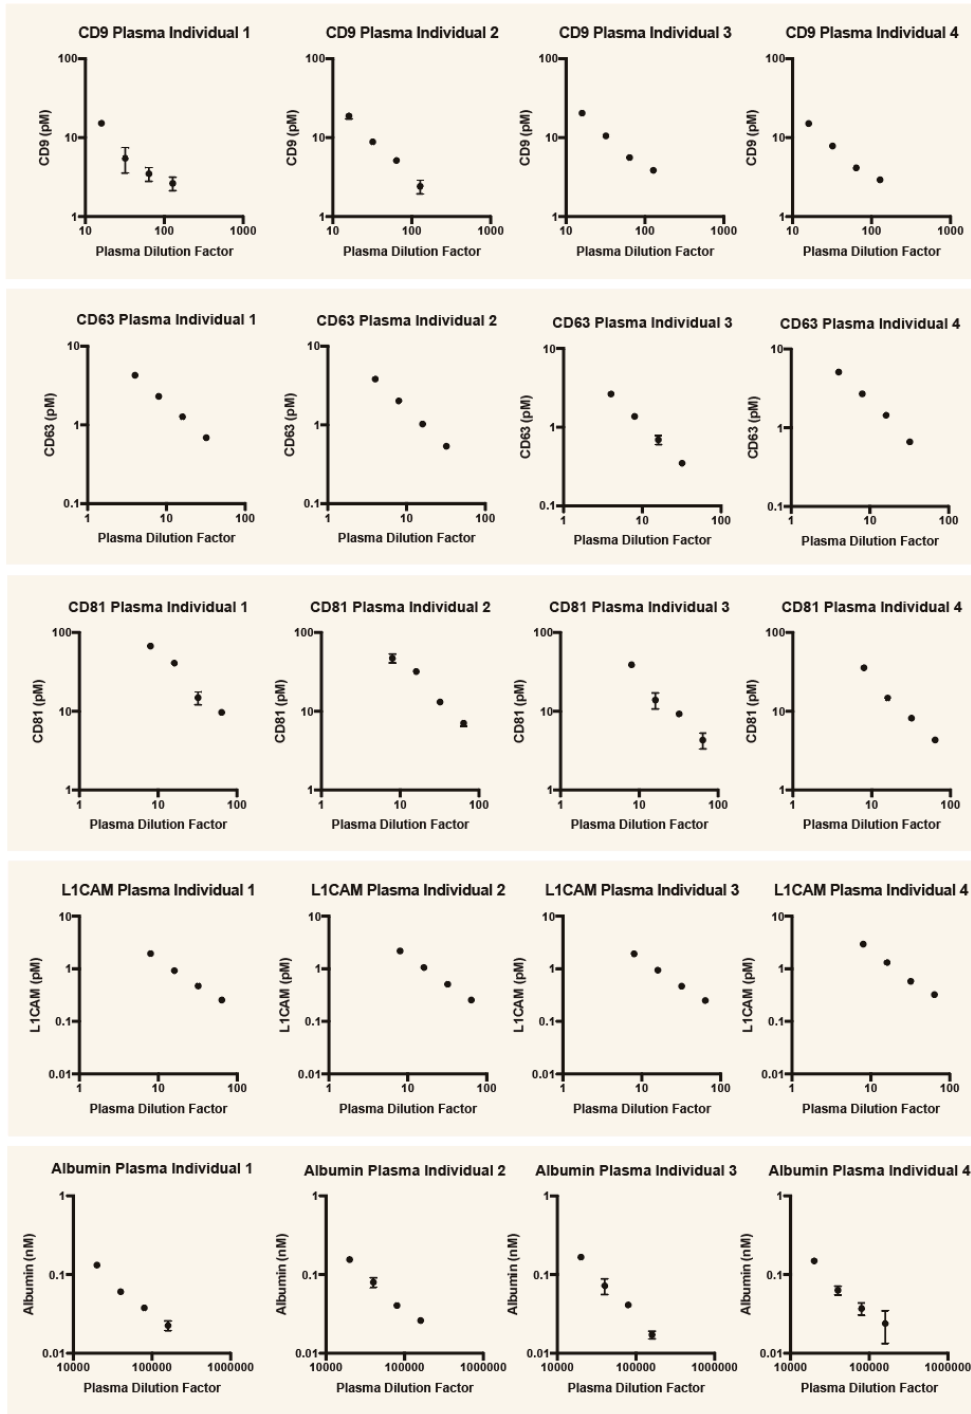

Supplementary Table 2: Analysis of reads from GTEx RNA-Seq Data supporting the existence of an L1CAM isoform lacking its transmembrane domain (table attached)

Supplementary Figure 1: We developed Simoa assays for the EV markers CD9, CD63, CD81 as well as for L1CAM and albumin. To ensure that our assays are accurate and precise, we performed validation experiments. Each assay demonstrated endogenous dilution linearity (parallelism) in human CSF (a) and plasma (b). Error bars represent the standard deviation from two technical replicates. Each linearity experiment was performed on the CSF and plasma from four individuals.

a.

b.

Supplementary Table 1: We spiked the recombinant protein used for the calibration curve into human plasma and CSF and quantified the percent recovery. Each assay recovered between 70-130% of the spiked concentration, indicating good assay precision. Data averaged across four individuals and two technical replicates.

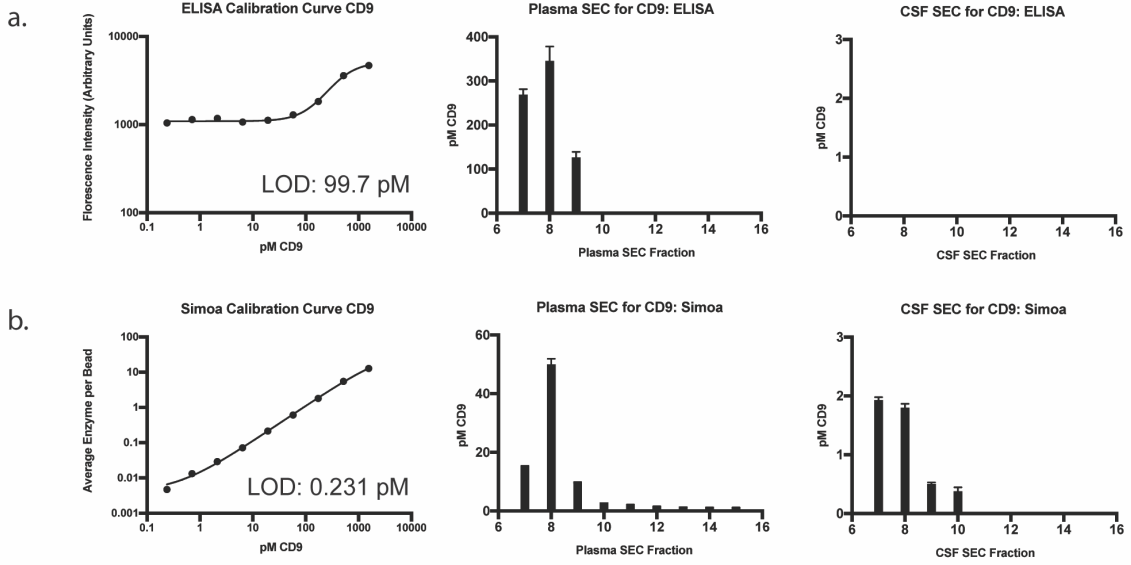

Protein	CSF Dilution Factor/Spike	Average Recovery (4 Individuals)	Plasma Dilution Factor/Spike	Average Recovery (4 Individuals)
CD9	32x+500	86%	32x+500	79%
	32x+1000	101%	32x+1000	74%
CD63	16x+10	106%	16x+10	83%
	16x+50	105%	16x+50	74%
CD81	32x+500	104%	32x+500	106%
	32x+1000	101%	32x+1000	94%
Albumin	400x+50000	90%	80000x+50000	85%
	400x+100000	85%	80000x+100000	90%
L1CAM	32x+500	106%	64x+500	102%
	32x+1000	107%	64x+1000	98%

Supplementary Figure 2: Comparison of ELISA and Simoa for EV quantification

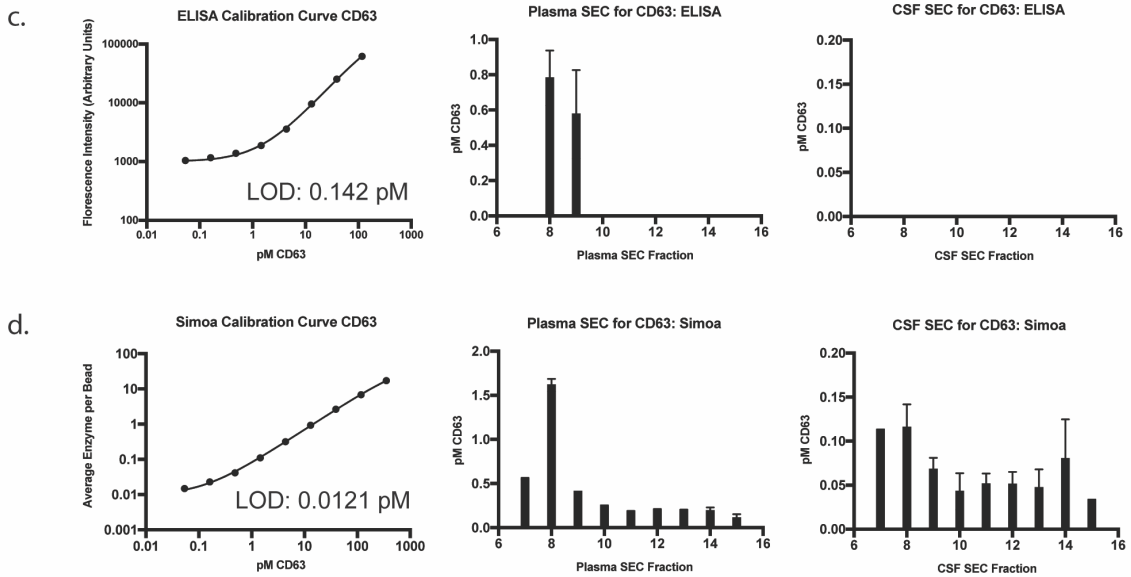

ELISA and Simoa were used to measure tetraspanin levels. For each assay, the same sample is directly compared by ELISA and Simoa for the calibration curve using protein standard (left), EV quantification of pooled plasma SEC fractions (middle) and EV quantification of pooled CSF SEC fractions (right) (a-f). The limits of detection (LOD) of the five Simoa assays were one to two orders of magnitude more sensitive than their respective standard ELISAs using the same set of antibodies for each target. Error bars represent the standard deviation from two technical replicates.

To ascertain whether this improved sensitivity was necessary for quantifying EVs in biological samples, human plasma and CSF samples were fractionated using a commercially available SEC column (Izon qEVoriginal 35nm), and fractions were evenly split for downstream analysis using Simoa, ELISA, and western blotting. Simoa quantified tetraspanins in EV fractions 7-10 (early fractions where EVs are expected) for all markers in both plasma and CSF (b,d,f). ELISA was able to quantify CD9 in expected EV fractions (7-10) for plasma, while only a subset of the expected EV fractions were quantifiable in plasma for CD63 and CD81. In contrast, none of the CSF fractions 7-10 were quantifiable by ELISA for any of the tetraspanins (a,c,e). When the SEC fractions were analyzed by western blot using the same volume of each fraction, we observed very high background in the plasma fractions (due to the high abundance of free proteins), but the tetraspanins were detectable and matched the general pattern of the Simoa results. We did not detect any tetraspanins in the CSF fractions (g). Simoa was the only assay method that allowed quantification of EVs in SEC fractions for both plasma and CSF.

Supplementary Figure 3: Mass spectrometry of L1CAM immunocaptured from plasma
 Mass spectrometry of full length recombinant L1CAM protein standard shows, as expected, peptides matching an isoform which includes Exon 25 (a). Mass Spectrometry of L1CAM immunocaptured from human plasma shows peptides matching the cytosolic domain at the C terminus (emphasized with black arrow) (b). Full length sequence of L1CAM displayed with peptides from mass spectrometry shown in green. Blue box indicates L1CAM transmembrane domain and red box indicates amino acid sequence encoded by Exon 25

Supplementary Figure 4: Analysis of reads from GTEx RNA-Seq Data indicating Exon 25 skipping in alternative splicing of L1CAM

Fraction of reads mapping to L1CAM isoform supporting skipping of L1CAM Exon 25 (junction reads spanning Exon 24 and Exon 26) vs. inclusion of Exon 25 from RNA-Seq GTEx data of various human organs.

Supplementary Figure 5: Affinity of L1CAM for recombinant alpha-synuclein

In order to assess nonspecific binding of UJ127 to alpha-synuclein, we followed the protocol from Min Shi et al. 2014. We utilized the same L1CAM antibody (Clone UJ127, Abcam) and nonspecific mIgG control antibodies (Santa Cruz Biotechnology) but used recombinant alpha-synuclein instead of plasma [1]. We found that that three times more recombinant alpha-synuclein binds to the UJ127 antibody than the mIgG control, exactly mirroring the effect in the paper.
