# 12 Abstract

13 Precise and simultaneous acquisition of multiple beneficial alleles in the genome to improve pig performance are pivotal for making elite breeders. Cytidine base editors 14 15 (CBEs) have emerged as powerful tools for site-specific single nucleotide replacement. 16 Here, we compare the editing efficiency of four CBEs in porcine embryonic cells and embryos to show that hA3A-BE3-Y130F and hA3A-eBE3-Y130F consistently results 17 18 in higher base-editing efficiency and lower toxic effects to *in vitro* embryo development. We also show that zygote microinjection of hA3A-BE3-Y130F results in one-step 19 20 generation of pigs (3BE pigs) harboring C-to-T point mutations, including a stop codon 21 in CD163 and in MSTN and induce beneficial allele in IGF2. The 3BE pigs showed 22 improved growth performance, hip circumference, food conversion rate. Our results 23 demonstrate that CBEs can mediate high throughput genome editing by direct embryo 24 microinjection. Our approach allows immediate introduction of novel alleles for 25 beneficial traits in transgene-free animals for pyramid breeding.

# 26 Introduction

27 Innovative approaches to accelerate improvement of livestock is urgently needed to 28 meet the increased demands for animal protein. Significant obstacles in livestock 29 breeding are limited dispersion of beneficial traits between different species and time 30 constrains required for crossbreeding and selection of livestock with improved 31 performance. Genome editing techniques, such as the clustered regularly interspaced 32 short palindromic repeat (CRISPR) system, have provided revolutionary progress for 33 improvement of pig performance at reduced cost and shortened time (Huang et al., 2014; Whitworth et al., 2014; Whitworth et al., 2016; Yang et al., 2011; Zhang et al., 34 35 2019). CRISPR/Cas9 mediated knockout of the MSTN gene in pigs led to improved 36 muscle development and decreased fat accumulation (Wang et al., 2017). Editing the 37 regulatory element within intron 3 of the IGF2 gene abolished repressor ZBED6 binding and resulted in improved meat production (Xiang et al., 2018). Most strikingly, 38 39 studies of CD163-knockout pigs from the Prather group provided proof-of-concept that 40 a single gene deletion establishes porcine reproductive and respiratory syndrome virus

41 (PRRSV)-resistant pigs, which has been further confirmed by several researchers 42 (Burkard et al., 2018; Tanihara et al., 2019; Whitworth et al., 2016). Most recently, 43 base editors (BEs) that fuse a cytidine or adenosine deaminase with a catalytically 44 impaired CRISPR-Cas9 mutant have been shown could directly and efficiently 45 generate precise point mutations in genomic DNA, without generating double-strand 46 breaks (DSBs) or requiring a donor template (Gehrke et al., 2018). These novel tools 47 have been used to induce single nucleotide modifications in a variety of animals (Kim 48 et al., 2017; Liu et al., 2018; Xie et al., 2019). Specifically, CBEs have been used to 49 induce C-to-T conversions of multiple genes in cell clones and then used as donors in SCNT to make immune-deficient pigs (Xie et al., 2019). Thus, BEs provide a strategy 50 for precise and efficient editing of single nucleotide polymorphisms (SNPs) to improve 51 52 livestock traits in pigs.

53 As we know, SNPs are the richest and most abundant form of genomic polymorphisms that constitute the genetic architecture of economic traits (Contreras-Soto et al., 2017; 54 Mora et al., 2016; Yue et al., 2019). Almost 66% of the total phenotypic variation of 55 pigs can be explained by SNPs (Lee et al., 2012). Functional SNPs related to various 56 57 economic traits such as meat quality and growth (Lee et al., 2012), fecundity (Ma et al., 2018) and virus resistance (Hess et al., 2016) have been identified. However, generation 58 of gene-edited pigs harboring beneficial SNPs is very inefficient, has a low throughput 59 60 and heavily relies on SCNT, a very complicated technology. The technical challenges of genetic engineering in somatic cells and SCNT greatly hinders widespread 61 62 application of genome editing in livestock for breeding.

63 In the present study, we screened CBE variants and found hA3A-BE3-Y130F and hA3A-eBE3-Y130F consistently result in higher base-editing efficiency in PEFs and 64 embryos. Pigs harboring C-to-T point mutations that create a stop codon in CD163 and 65 66 in MSTN and introduce a beneficial allele in intron 3-3072 of the IGF2 gene were generated in one step with direct zygote microinjection of hA3A-BE3-Y130F. The 67 genetically engineered pigs showed disrupted gene expression of CD163 and MSTN 68 69 and enhanced expression of IGF2, which resulted in improved growth performance. 70 We found that CBEs mediated precise and efficient genome editing at multiple sites 71 with direct embryo injection, circumventing the need for SCNT and providing a 72 potential process for prospective pyramid breeding in pigs.

## 73 **Results**

## 74 CBEs-mediated base editing at multiple loci in PEFs

75 In order to screen suitable tools for base editing, the editing efficiency of four CBEs –

rA1-BE3, hA3A-BE3, hA3A-BE3-Y130F and hA3A-eBE-Y130F – were compared in

77 PEFs. Considering the potential for pyramid breeding, target loci from CD163, MSTN

and *IGF2* genes were selected. Premature stop codons (R4312STOP and Q218STOP)

79 were generated by a single C-to-T conversion at the target sites in *CD163* and *MSTN*,

- 80 which are expected to confer double-muscled and porcine reproductive and respiratory
- 81 syndrome virus (PRRSV) resistance traits in pigs, respectively (Fig. 1A). For *IGF2*, a

82 point conversion at the target sites of Bama pig would abrogate BED-type containing 6

83 (ZBED6) binding, resulting in enhanced IGF2 expression in skeletal muscle and 84 improved lean meat yield (Van Laere et al., 2003) (Fig. 1A).

Three sgRNA candidates targeting exons of porcine CD163, MSTN and IGF2 genes 85

were synthesized and transfected into PEFs with vectors expressing rA1-BE3, hA3A-86

87 BE3, hA3A-BE3-Y130F and hA3A-eBE-Y130F. After 48 h of culturing, cells were

88 collected and target sequences were PCR amplified for sequencing. The editing

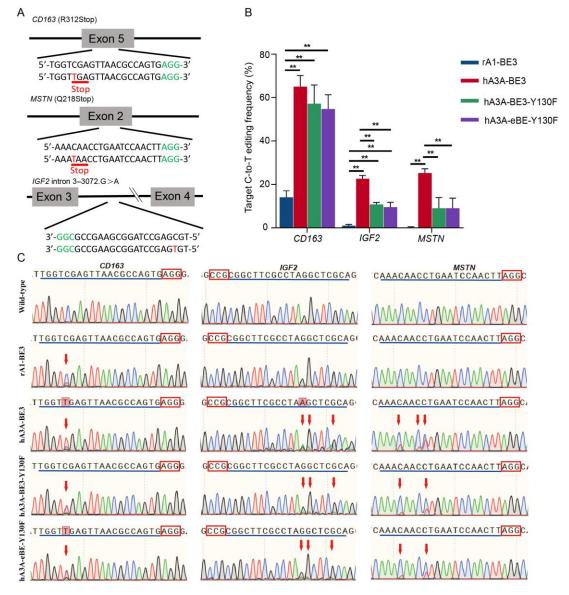

89 efficiencies of hA3A-BE3, hA3A-BE3-Y130F and hA3A-eBE-Y130F were

90 significantly higher than that of rA1-BE3 (Fig. 1B, C). We also observed the editing

91 efficiencies varied among the three genes, with the IGF2 target site showing lowest

92 editing efficiency.

93

94 Figure 1 Base editing at multiple loci in PEF cells by different base editors. A Schematic of the CD163, MSTN

95 and IGF2 gene structure. One sgRNA targeting each gene was designed. The codon to be modified is underlined. 96

The targeting site is in red and the PAM region is in green. **B** The C-to-T editing frequency of different base

97 editors in multiple target sites were detected by sequencing. C Representative sequence chromatogram of different

98 base editors in the target site of *CD163*, *MSTN* and *IGF2*. Red box shows the C-to-T substitutions at target sites.

99 We next explored whether hA3A-BE3 could generate simultaneous C-to-T conversions

100 in multiple genes in PEFs. The mixed sgRNAs were co-transfected with hA3A-BE3-

101 expression vectors into PEFs, which were then cultured for 48 h before single-cell

102 sorting by FACS. Next, thirty-nine single-cell colonies were selected and genotyped by

103 Sanger sequencing after 8-14 days of cell culture. Among the 39 colonies, 28.21%

104 (11/39) colonies showed C-to-T substitution among all three genes (Fig. 2A). In 105 addition, 20 colonies (two for *CD163* and *IGF2*, sixteen for *CD163* and *MSTN*, and two

106 for *IGF2* and *MSTN*) showed double-gene base editing, and 4 colonies (three for *CD163*,

107 one for *MSTN*) showed single-gene base editing (Fig. 2A). Overall, 20.51% (8/39)

108 colonies contained the targeted C-to-T homozygous mutation at all three gene sites (Fig.

109 2B). For each single gene, 76.92% (30/39), 28.21% (11/39) and 64.10% (25/39) of the

110 colonies were homozygous mutants in CD163, IGF2 and MSTN, respectively. Indel

111 incorporation was also found in *CD163* (10.25%), *IGF2* (51.28%) and *MSTN* (15.38%)

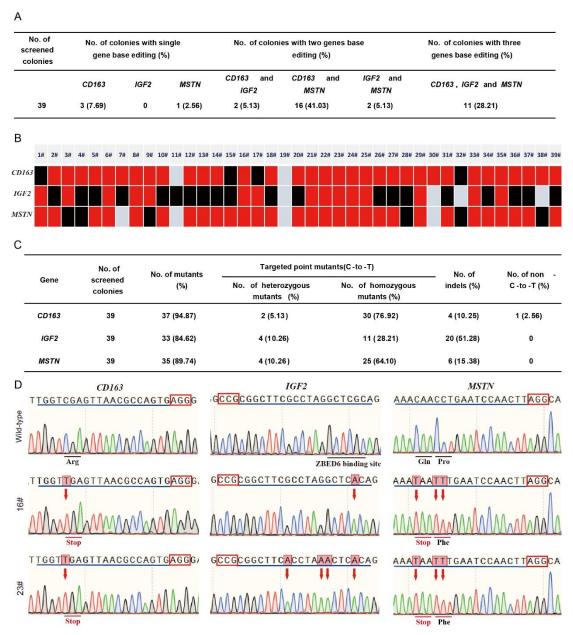

112 (Fig. 2C). In addition, an unwanted C-to-A substitution at the targeted position in

113 CD163 was detected in one colony (Fig. 2C). Thus, results show that hA3A-BE3 can

114 efficiently induce biallelic C-to-T substitutions in three genes during one transfection

115 of PEFs. Sanger sequence results further confirmed the high frequency of targeted C-

116 to-T conversions (Fig. 2D).

117

120 conversion of C-to-T, and the black represents an indels. C Summary of product types of base editing by hA3A-

121 BE3 in porcine somatic cells. **D** Sanger sequencing chromatograms of the selected single-cell colonies. The red

122 arrow indicate expected substitutions at target sites.

# 123 Efficient one-step base editing for multiple genes in porcine embryos via embryo124 injection

125 We next detected the editing efficiency of these four CBEs in porcine embryos. In vitro

126 transcribed sgRNAs (CD163-sgRNA and MSTN-sgRNA) and BE3, hA3A-BE3,

- 127 hA3A-BE3-Y130F and hA3A-eBE-Y130F mRNAs were co-injected into porcine
- 128 parthenogenetically activated (PA) oocytes. The injected PA embryos were cultured for
- 129 7 days to determine developmental competency. The blastocyst rate of embryos
- 130 injected with *CD163*-sgRNA and mRNA of rA1-BE3, hA3A-BE3, hA3A-BE3-Y130F,

131 and hA3A-eBE-Y130F were 15.8% (27/171), 0.96% (4/415), 15.63% (25/160) and

- 132 17.27% (24/139) (Fig. 3A), respectively. The blastocyst rate of embryos injected with
- 133 *MSTN*-sgRNA and mRNA of rA1-BE3, hA3A-BE3, hA3A-BE3-Y130F, and hA3A-
- 134 eBE-Y130F were 7.36% (12/163), 1.54% (9/585), 8.63% (22/255) and 8.52% (15/176)
- 135 (Fig. 3B), respectively. The rates of embryos injected with CBEs are significantly lower
- than the rates of the control embryos injected with water, indicating that CBEs might
- 137 affect early embryonic development competency. Notably, the hA3A-BE3 injection
- 138 might lead to detrimental effects in embryo development, which may result from the 130
- high off-target rate of hA3A-BE3 in mRNA (*Zhou et al., 2019*).
- 140 Single blastocysts were lysed individually for genotyping by Sanger sequencing. Of the 141 screened blastocysts, 85.2% (23/27) for rA1-BE3, 100% for hA3A-BE3 (4/4), 100%
- 142 (24/24) for hA3A-BE3-Y130F and 100% (23/23) for hA3A-BE5 (4/4), 100%
- 142 (24/24) for IASA-BES-1150F and 100% (25/25) for IASA-BES-1150F were 143 identified to have targeted mutations in *CD163* (Fig. 3A). In one hA3A-BE3 injected
- blastocyst, C-to-T conversions also occurred outside the editing window. In addition to
- the specific C-to-T mutation, a few C-to-A substitutions were also found in rA1-BE3
- 146 (7.4%) and hA3A-BE3-Y130F (12.5%) injected blastocyst, as well as an indel in a rA1-
- 147 BE3-injected blastocyst (Fig. 3A).
- 148 The targeted mutation rate in the *MSTN* injected group was 33.3% (3/9) for rA1-BE3,
- 149 66.7% (4/6) for hA3A-BE3, 55.6% (10/18) for hA3A-BE3-Y130F and 78.6% (11/14)
- 150 for hA3A-eBE-Y130F (Fig. 3B). We also detected indels in 1 (11.1%, 1/9) blastocyst
- 151 in the rA1-BE3 group, 3 (16.7%, 3/18) blastocysts in the hA3A-BE3-Y130F group and
- 152 2 (14.3%, 2/14) blastocysts in the hA3A-eBE-Y130F group (Fig. 3B). These data
- 153 indicate rA1-BE3, hA3A-BE3-Y130F and hA3A-eBE-Y130F might induce DSB in the
- 154 genome, resulting in indels (Fig. 3B). At the *MSTN* target site, we also have detected
- non-C-to-T conversion in 1 (5.6%, 1/18) blastocyst of the hA3A-BE3-Y130F group
- and 1 (8.3%, 1/12) blastocyst of the hA3A-eBE-Y130F group (Fig. 3B).
- 157 The targeted C-to-T mutation frequency in each blastocyst of different base editors is
- shown in Fig 3C and Fig 3D. At both the *CD163* and *MSTN* targeting sites, the editing
- 159 efficiencies of hA3A-BE3-Y130F and hA3A-eBE-Y130F were significantly higher
- 160 than that of rA1-BE3. In addition, the efficiency of hA3A-BE3 was significantly higher
- 161 than that of rA1-BE3 at the *MSTN* gene site.

- 169 injection

А

- 170 Although hA3A-BE3 mediated the highest editing efficiency in both cell transfection
- 171 and embryo injection, it also caused the greatest detrimental effect on embryonic

development after injection. Hence, hA3A-BE3-Y130F was selected for pig zygote 172 injection to base edit multiple genes in one step. The mixed sgRNAs and hA3A-BE3-173 174 Y130F mRNA was co-injected into the cytoplasm of one-cell stage zygotes obtained 175 from nine Bama pigs. Thirty-eight injected zygotes were then transferred into three surrogate pigs (Fig. 4A). One surrogate pregnancy developed to term, resulting in a 176 177 litter of five pigs with four healthy offspring (Fig. 4A, 4B). Genotyping showed that all five pigs harbored mutations in the three genes. At the target site of CD163, ~100% of 178 179 the site-specific C-to-T mutations was achieved at the CD163 c.2142C site for all pigs, 180 resulting in a stop codon with a 312 arginine conversion (Fig. 4C, D). The target deep sequence results showed that the intron 3-3072.G>A in the *IGF2* gene were detected in 181 pigs with an efficiency of 46% (1920901), 98% (1920902) and 45% (1920905) (Fig. 182 183 4C, D). In addition, an unwanted mutation (intron 3-3067.G>A and intron 3-3068.G>A) 184 were detected in pigs with an efficiency of 46% (1920901), 98% (1920902, 1920904) and 45% (1920905) (Fig. 4C, D). Moreover, three pigs (1920901, 1920904 and 185 1920905) harbored undesired indels at the IGF2 target site (Fig. 4C, D). All five pigs 186 187 harbored the target Q218Stop mutation in the MSTN gene, but two of the five pigs were 188 heterozygous with a frequency of 50% and 41% (Fig. 4C, D). Unwanted L216L and 189 P219F mutations were also detected in all pigs with high efficiency (Fig. 4C, D). Complete genotyping results are shown in Supplementary Fig. 1A and Fig. 1B. Notably, 190 the 1920902 piglet harbored a biallelic C-to-T transition in three genes. Sequencing 191 192 results indicate that all 3BE pigs were homozygous at CD163 sites, one piglet (1920904) 193 was homozygous at MSTN sites, and two pigs (1920902 and 1920903) were 194 homozygous at IGF2 sites (Fig 4D). In addition, we detected that 1920901, 1920902 195 and 1920905 were chimeric at MSTN sites. Sanger sequencing analyses of ten POTs 196 showed that no off-target mutations were found in four of the base-edited pigs 197 (Supplementary Fig. 2).

For mRNA expression analysis, g-PCR showed that the mRNA expression of IGF2 in 198 199 the heart, liver, lung, kidney, back muscle and gluteus muscle tissues of the piglet 200 (1920901) was significantly higher than expression in wild-type (WT) pigs (Fig. 4E). The unregulated protein expression of IGF2 was also confirmed in the liver and lung 201 202 of piglet (1920901) (Fig. 4F). Protein analysis demonstrated that CD163 and MSTN 203 couldn't be detected in the CD163 R312Stop and MSTN Q218Stop mutant piglet 204 (1920901) (Fig. 4F). However, the blood physiology and biochemistry reflected no significant difference between the 3BE and WT pigs (Table S2, S3). 205

206

207 Figure 4 Generation MSTN, CD163 and IGF2 gene mutations in pigs via zygote injection. A Summary of

208 generation of three genes mutant pigs by using direct zygote injection. **B** Representative photograph of newborn

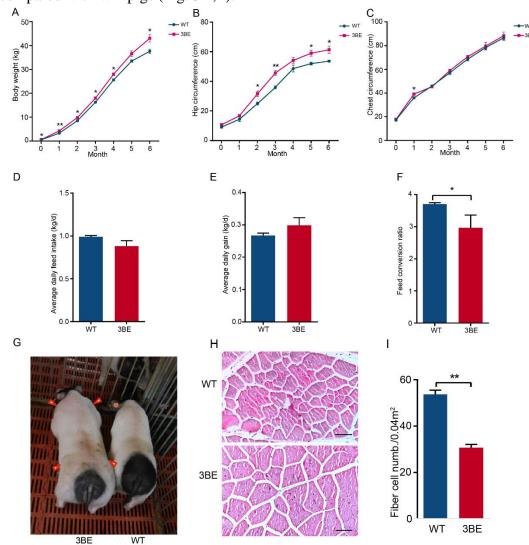

209 three genes mutant piglets. C The genotype of newborn piglets at CD163, IGF2 and MSNT. D Summary of

- 210 genotypes of newborn piglets from targeted deep sequencing. C-to-T substitutions and indels are shown in red. E
- 211 Western blot was used to detect the expression of *CD163*, *IGF2* and *MSTN* protein in the liver, lung, back muscle
- and gluteus muscle of WT and 1920901 piglets. F The mRNA expression of IGF2 in the heart, liver, spleen, lung,
- kidney, back muscle and gluteus muscle of WT and 1920901.

#### 214 Improved growth performance in 3BE founder pigs

- 215 The body weight, body length, body height, hip circumference and chest circumference
- 216 were measured in 3BE female pigs (n=3) and age matched WT female pigs (n=3). The

birth weight of 3BE pigs was significantly higher than that of WT pigs (0.62±0.019 vs. 217 0.52±0.043, P=0.036) (Supplementary Fig.3 A). Results of growth performance 218 219 showed that the 3BE pigs (0-6 months of age) grew faster than age-matched WT pigs 220 (Fig.5 A). The hip circumference of 3BE pigs was also higher than that of WT pigs at 221 every measuring time (Fig.5 B). The chest circumference, body length and body height 222 of 3BE pigs were similar with WT pigs (Fig.5 C; Supplementary Fig.3 B, C). Results 223 of average daily feed intake (ADF) (Fig.5 D), average daily gain (ADG) (Fig.5 E) and 224 feed conversion ratio (FCR) showed that 3BE pigs (2 - 5 months of age) had lower FCRs than age-matched WT pigs (Fig.5 F). The pictures of 3BE pigs are shown in the 225 Figure 5 G which indicate a higher hip circumference of 3BE pigs. Histological analysis 226 of tissue slices of the gluteus muscle showed increased muscle fiber size in 3BE pigs 227 228 compared with WT pigs (Fig. 5H, I).

229 230

Figure 5 Growth performance of three genes mutant pigs. The body weight (A), saddle width (B), chest

circumference (C), average daily feed intake (D), average daily gain (E) and feed conversion ratio (F) of 3BE pigs
and age-matched WT (female and male) piglets were measured. G Images of 3 month-old female and male of 3BE
and WT pig. H, I HE staining of gluteus muscle in WT and 3BE pigs and the changes of myofiber density in 3BE
pigs.

# 235 **Discussion**

Developing pig breeds with desirable characteristics such as high growth performance, meat quality, reproductive success, and disease resistance using traditional breeding methods is time consuming and cost prohibitive. Developing pigs using gene editing provides a reliable and rapid solution to improving livestock traits. In this study, a selective and efficient base editor was successfully used to engineer several beneficial traits by simultaneously editing multiply gene sites using one-step zygote injection in pigs.

With the continuous innovation and optimization of gene editing, many evolved 243 244 versions of CBE tools have been developed to improve editing efficiency and accuracy 245 (Cheng et al., 2019; Koblan et al., 2018; Zong et al., 2018). In this study, we first 246 compared the editing efficiency of different CBEs at target sites in PEFs. All base editors were able to generate targeted site mutations, but the editing efficiency of CBEs 247 248 varied at different target positions. The CBEs hA3A-BE3 and rA1-BE3 consistently showed the highest and lowest editing efficiency, respectively. In addition to the 249 250 specific conversion of C-to-T mutation, undesired indels were also found at expected 251 positions in these three genes. However, the efficiency of indel incorporation at the IGF2 position was much higher than that of other genes. These results suggest that 252 253 hA3A-BE3 may significantly improve the efficiency of base excision repair during C-254 to-T conversions in the high GC content regions (Van Laere et al., 2003) and 255 subsequently induce indels in this region. These undesired results were in accordance 256 with previous studies in human cells, which indicated the products may be dependent on uracil N-glycosylase (UNG) (Komor et al., 2017). 257

258 Even after the birth of Dolly more than two decades ago, SCNT is still quite inefficient, 259 making the generation of genetically modified pigs through SCNT a continuous 260 challenge. Zygote injection of Cas9 or BEs mRNA and sgRNA complexes to target 261 single point mutation have been reported (Liang et al., 2017; Liu et al., 2018), but our 262 current work is the first to characterize one-step multiple site-specific base editing. In 263 this work, we found that almost all the injected CBE mRNA complexes have a negative influence on embryo development competence. This is especially true for hA3A-BE3 264 265 injections which may correspond with the high off-target rate of hA3A-BE3 in mRNA 266 (Zhou et al., 2019). The editing efficiency of these CBE members were also variable 267 depending on the differing targeted genes in embryos. Almost all embryos (85.2%~100%) showed a single base mutation at the CD163 target site, while 268 33.3%~78.6% embryos showed a mutation at the MSTN target site. This variable 269 270 editing efficiency may be associated with the different positions of the targeted site in 271 genes. In addition, we demonstrated that the new CBEs (hA3A-BE3-Y130F and hA3A-272 eBE-Y130F) significantly increased targeted mutation efficiency in porcine blastocysts compared to their predecessor. However, at a cellular level, these new CBEs 273 unexpectedly induced indels (0~16.7%) and non-C-to-T conversions (0~12.5%) in 274 275 blastocysts at a higher frequency than that seen in a previous study (Komor et al., 2016). 276 Other studies have also reported similar frequency of indels (6.7-35.6%) in Psen1-

targeted mice (*Sasaguri et al., 2018*), and the different frequency of indels in genes
were also found in the study of *Dmd*-targeted (11.1%) and *Tyr*-targeted (28.6%) mice
(*Kim et al., 2017*).

280 Most economic traits in pigs are complex, quantitative, and usually controlled by 281 multiple genes. Because of this complexity, trait improvement requires stacking of 282 natural and induced mutations; therefore, precision and high-throughput single-base 283 substitution will be vital for designed breeding. We share our proof-of-concept results 284 that show CBE-mediated trait improvement in pigs is feasible. Using one-step zygote injection, we generated 3BE pigs that carried precise mutations in CD163, IGF2 and 285 286 MSTN. The hA3A-BE3-Y130F efficiently and precisely targeted C-to-T conversion 287 with few proximal off-target mutations and negligible negative effects on embryo 288 development, which is consistent with previous reports in mammalian cells (Gehrke et al., 2018; St Martin et al., 2018). 289

290 Our approach can help livestock breeders bypass time constraints with improving 291 economic traits in pigs. Our approach can be used to directly create desirable mutations 292 in a natural or genetically modified background using one-step zygote injection. To the 293 best of our knowledge, this is the first report highlighting the highly efficient base 294 conversion of three economic trait-related genes in pigs using a one step process. These 295 findings indicate an achievable and rapid genetic improvement for multiple economic 296 traits that conventional breeding and selection strategy could not accomplish. Beyond 297 enhancing beneficial trait variation in pigs, our approach opens a new chapter in gene 298 pyramid breeding for livestock.

# 299 Materials and Methods

## 300 Animals

Bama miniature pigs were maintained at the Beijing Farm Animal Research Center,
Institute of Zoology, Chinese Academy of Sciences. All pig studies were conducted
according to experimental practices and standards approved by the Institutional Animal
Care and Use Committee of the Institute of Zoology, Chinese Academy of Sciences.

## 305 Vector construction

- 306 *MSTN*-sgRNA, *CD163*-sgRNA and *IGF2*-sgRNA were designed following the NGG 307 rule. Two complementary oligonucleotides of sgRNAs were synthesized and then 308 annealed to double-stranded DNAs. The annealed products were then cloned into the 309 BsaI-digested pGL3-U6-sgRNA expression vectors. sgRNA-oligo sequences used
- above are listed in Supplementary Table 1.

# 311 mRNA and sgRNA preparation

- 312 rA1-BE3, hA3A-BE3, hA3A-BE3-Y130F and hA3A-eBE3-Y130F plasmids were
- 313 obtained from Addgene. The plasmid was linearized with Not I, and mRNA was
- 314 synthesized using an in vitro RNA transcription kit (mMESSAGE mMACHINE<sup>™</sup> T7
- 315 ULTRA Transcription Kit, AM1345, Invitrogen). sgRNAs were amplified and
- 316 transcribed in vitro using the MEGAshortscript<sup>™</sup> T7 Transcription Kit (AM1354,

317 Invitrogen) according to manufacturer's instructions. sgRNA primer sequences are

318 listed in Supplementary Table 1.

#### 319 **PEFs culture and transfection**

320 Pig fetal fibroblasts (PFFs) were isolated from 35-day-old fetuses of Bama pigs. A day 321 before transfection, PFFs were thawed and cultured in PFFs culture medium 322 (Dulbecco's modified Eagle's medium [DMEM, HyClone]) and supplemented with 15% fetal bovine serum (FBS, HyClone), 1% nonessential amino acids (NEAA, Gibco), and 323 2 mM GlutaMAX (Gibco). Next,  $\sim 1 \times 10^6$  PFFs were electroporated with rA1-BE3, 324 hA3A-BE3, hA3A-BE3-Y130F or hA3A-eBE-Y130F (4 µg), and sgRNA-expressing 325 vectors (2 µg of each sgRNA). The electroporated cells were recovered for 48 h, split 326 into single cells and cultured in 96-well plates for 8 days to form colonies by flow 327 328 cytometry. We also collected 10,000 single GFP positive cells to detect the efficiency 329 of different base editor systems. Cell lysates were then used as templates for PCR. Next, PCR products were used for sub-cloning into the pMD18-T vector (Takara) and 330 331 sequenced to determine mutation efficiency. Cell colonies with target mutations were 332 identified using PCR and then sequenced. Primer sequences are listed in Supplementary 333 table 1.

#### 334 Microinjection of pig embryo and zygotes

Porcine ovaries were obtained from a local slaughterhouse, and porcine oocyte 335 collection, in vitro maturation, parthenogenetic activation (PA) and the reagent 336 337 formulation were conducted as described in our previous studies (Wang et al., 2015). 338 Zygotes from Bama miniature pigs were collected within 24 h after insemination and 339 transferred into manipulation medium (0.75 g HEPES, 9.5 g TCM-199 powder, 0.05 g NaHCO<sub>3</sub>, 1.755 g NaCl, 0.05 g penicillin, 0.06 g streptomycin, and 3.0 g BSA, in a 340 341 final volume of 1L in Milli-Q water, pH 7.2–7.4). The protocol for microinjection of 342 oocytes and pronuclear stage embryos has been described in detail in our published protocols (Wang et al., 2015). Briefly, a mixture of rA1-BE3, hA3A-BE3, hA3A-BE3-343 344 Y130F and hA3A-eBE3-Y130F mRNA (200 ng/ul), and sgRNA (50 ng/ul) was co-345 injected into the cytoplasm of porcine PA embryos and pronuclear-stage zygotes. The injected embryos or zygotes were then cultured in PZM3medium, pH 7.4, 346 347 supplemented with 3 mg/ml BSA, for 7 days or transferred to surrogate pigs.

## 348 Single embryo PCR amplification and pig genotyping

- Injected embryos were collected at the blastocyst stage. Genomic DNA was extracted with lysis buffer (1% NP40) at 55 °C for 40 min and 95 °C for 15 min, and then were used as a template for PCR, and subjected to Sanger sequencing. Genomic DNA of newborn pigs was extracted from ear clips for PCR and subjected to Sanger sequencing and targeted deep sequencing. All primers for detection are listed in Supplementary Table 1.
- $354 \quad 1able 1.$

# 355 Targeted deep sequencing

Target sites were amplified from genomic DNA using i5 Phusion polymerase. The paired-end sequencing of PCR amplicons was performed by Sangon Biotech (Shanghai), using an Illumina MiSeq. The primers are listed in supplementary Table 1.

#### 359 Quantitative real-time PCR

Total RNA was extracted from porcine heart, liver, spleen, lung, kidney, back muscle 360 361 and gluteus muscle tissues with TRIzol (Invitrogen). Total RNAs were used for reverse transcription using a FastQuant RT Kit (Tiangen Biotech). qPCR reactions were 362 performed using TaKaRa SYBR Premix Ex Taq (TaKaRa, Tokyo, Japan) with an 363 364 Agilent Mx3005p (Agilent Technologies) quantitative PCR instrument. The housekeeping gene, GAPDH, was used as an internal control. Relative expression of 365 *IGF2* was calculated using the comparative cycle threshold  $(2^{-\Delta\Delta Ct})$  method. All primer 366 sequences are shown in Supplementary Table 1. 367

#### 368 Western blot analysis

- Liver, lung, back muscle and gluteus muscle tissues were dissected and frozen
   immediately in liquid nitrogen and stored at -80°C until use. Total protein was extracted
- 371 using the Minute Total Protein Extraction Kit (Invent Biotechnologies, Inc.). Proteins
- 372 were loaded to SDS-PAGE and transferred onto PVDF membranes. Membranes were
- 373 blocked with 5% fat-free milk for 1 h at room temperature. Primary antibodies, anti-
- 374 CD163 (ab87099, 1:500; Abcam), anti-IGF2 (ab170304, 1:100; Abcam) anti-MSTN
- 375 (ab98337, 1:100; Abcam), and anti-Tubulin (SC9104, 1:3,000; Santa Cruz) were
- incubated with the membranes overnight at 4°C. Next, membranes were incubated with
- 377 HRP-conjugated secondary antibodies for 1h at room temperature. All signals were
   378 detected using ECL Prime chemiluminescence (GE Healthcare) according to the
   379 manufacturer's protocols.

#### 380 **Off-target assay**

- Ten potential off-target sites (POTs) for each sgRNA were predicted for site-specific edits by a base-editor system, according to an online design tool CAS-OFFinder (http://www.rgenome.net/cas-offinder/)(*Bae et al., 2014*). All POTs were amplified by PCR and then subjected to sequencing. All primers for amplifying the off-target sites
- are listed in Supplementary table S1.

#### 386 Histochemistry

- Three tissue samples  $(0.5 \text{ cm} \times 0.5 \text{ cm} \times 0.5 \text{ cm})$  were randomly chosen from the gluteus muscles of 3BE pigs at 6 months of age. The tissues were fixed in 4% paraformaldehyde for 24 h and then moved into 70% alcohol. Samples were embedded
- in wax blocks, sectioned at  $5\mu m$ , and then stained with hematoxylin and eosin (H&E).
- 391 Five different microscopic fields were randomly chosen, and muscle fiber density was
- defined as the number of myofibers per  $0.04 \text{ mm}^2$  of the muscle cross-sectional area.

## 393 **Blood analysis**

- 394 Venous blood samples were collected to determine blood physiology and biochemistry.
- 395 Samples were tested in the Beijing Lawke Health Laboratory.
- 396 Statistical analysis
- 397 Statistical data are expressed as mean  $\pm$  SEM and at least three individual
- 398 representations were included in all experiments. Statistical significance was analyzed
- 399 with a Student's t test (unpaired) or two-way ANOVA using GraphPad prism software
- 400 6.0. A p-value < 0.05 was considered statistically significant. \*\*, P < 0.01; \*, P < 0.05.
