27 **Abstract:** Though chemically cross-linked by EDC/NHS endows collagen membrane
 28 with promising mechanical properties, it is not conducive to modulation of foreign
 29 body reaction (FBR) after implantation or guidance of osteogenesis. In our previous
 30 research, we have found that macrophages have a strong regulatory effect on tissue
 31 and bone regeneration during FBR, and EGCG modified membranes could adjust the
 32 recruitment and phenotypes of macrophages. Accordingly, we develop the
 33 EGCG-EDC/NHS membranes, prepared with physically immersion, while the surface
 34 morphology of the membrane was observed by SEM, the biological activity of
 35 collagen was determined by FTIR, the activity and adhesion of cell culture *in vitro*,
 36 angiogenesis and monocyte/macrophage recruitment after subcutaneous implantation,
 37 etc. are characterized. It could be concluded that EGCG-EDC/NHS collagen
 38 membrane is hopeful to be used in implant dentistry for it not only retains the
 39 advantages of the collagen membrane itself, but also improves cell viability, adhesion
 40 and vascularization tendency. However, the mechanism that lies in the regenerative
 41 advantages of such membrane needs further exploration, but it is certain that the
 42 differences in surface morphology can have a significant impact on the reaction
 43 between the host and the implant, not to mention macrophage in bone regeneration.

 45

46 **1. Introduction**

47 Guided bone regeneration (GBR) technology takes advantage of barrier membrane to
 48 compartmentalize soft and hard tissue. It protects the hard tissue from an invasion of
 49 the relatively fast-growing soft tissue, thus creates sufficient space and provides
 50 stability for osteogenic cell migration in the meanwhile (Melcher, 1976). Currently,
 51 collagen, the main organic component of extracellular matrix (ECM) and bone, is the
 52 most common resorbable source for membrane fabrication. A meta-analysis revealed
 53 that the survival rate of implant with the application of collagen membrane were close
 54 to 100% both in simultaneous and subsequent implant placement (Wessing, Lettner, &
 55 Zechner, 2018). However, its high biocompatibility also becomes its fatal flaw, which
 56 limits the mechanical properties of the collagen membrane. Without the addition of
 57 crosslinking agents, the integrity of the membrane may not be able to maintain
 58 throughout the entire process of bone regeneration to provide sufficient support
 59 (Meyer, 2019). Although the exposure of membrane is slightly related to the addition
 60 of crosslinker, it is not statistically significant (30%) (Wessing et al., 2018). This
 61 observed degradation time is markedly longer than that of collagen membrane, which
 62 is reported to be completely resorbed 1 to 2 weeks after exposure [18, 34]. The
 63 prolonged degradation time of matrix barrier seems to provide prolonged protecting
 64 of the underlying graft supporting the bone regeneration process. During this healing

65 process, all exposures did resolve within 6-7 weeks and no membrane had to be
66 extracted. The ridge width gain in both groups was sufficient to allow for the
67 successful placement of dental implants in all 14 subjects without any complication
68 (Eskan, Girouard, Morton, & Greenwell, 2017). Therefore, to enhance mechanical
69 properties with low cytotoxicity and low antigenicity,
70 1-ethyl-3-(3-dimethylaminopropylcarbodiimide hydrochloride (EDC) in the presence
71 of N-hydroxy-succinimide (NHS) collagen membrane was selected as our target
72 (Akhshabi, Biazar, Singh, Keshel, & Geetha, 2018; Bax et al., 2017). Apart from the
73 degradation rate of membranes, immune environment of the implant site is another
74 factor that determines the success or failure of the surgery (El-Jawhari, Jones, &
75 Giannoudis, 2016). Especially in periodontitis, a chronic and degenerative
76 inflammatory disease which affects approximately 10% of the world's population, the
77 inflammatory environment makes it harder to conduct tissue engineering with
78 biomaterials, thus elevates the importance of immune modulation to rebuild balance
79 (Kurashima & Kiyono, 2017). Epigallocatechin-3-gallate (EGCG) as one of the main
80 polyphenols in tea could serve as a crosslinker for scaffolds (Honda et al., 2018),
81 showing bioactive effects in various aspects, especially in dental restoration (Liao et
82 al., 2020). Compared with pure collagen membrane, its anti-inflammatory (Lagha &
83 Grenier, 2019; Wu, Choi, Kang, Kim, & Shin, 2017), anti-fibrosis (Wang, Yang, Yuan,

84 Yang, & Zhao, 2018), pro-osteogenic (Lin et al., 2018), macrophage phenotypes
 85 regulatory (Chu et al., 2019) effects are all prompt to rescue the pro-long
 86 inflammation and help the establishment of ideal microenvironment to provide
 87 promising signal in regeneration (Chu et al., 2020). Considering its promising traits,
 88 EGCG was cross-linked to attach the commercial EDC/NHS collagen, and the
 89 modification of EGCG was adjusted at 0.064% w/v, where it is reported to possess
 90 appropriate mechanical properties, anti-inflammatory effects, and cell viability
 91 promotion in previous report (Chu et al., 2016). To ensure that the developed EGCG
 92 modified EDC/NHS collagen membrane meets the need of GBR, its physical,
 93 chemical and biological properties was characterized by means of investigation on
 94 surface morphology, FTIR spectra, DSC statistics, *in vitro* cell viability and integrin
 95 expression, and *in vivo* vascularization and monocyte/ macrophage recruitment. The
 96 aim of this study is to fabricate 0.064% EGCG EDC/NHS collagen membranes (**Fig.**
 97 **1**) with the improvement of cell viability and adhesion, as well as revascularization.

Fig. 1. Schematic graph of loading 0.064% EGCG to EDC/NHS collagen membrane

100 **2. Materials and Methods**

101 **2.1 Materials**

102 Commercially available EDC/NHS collagen membranes (Dentium) in size of
103 10mm×20mm were purchased. EGCG was purchased from Jiang Xi Lv Kang Natural
104 Products (Jiang Xi, China). All solvents and chemicals employed in the process were
105 analytical grade and were used without further purification. The EGCG modified
106 EDC/NHS collagen membrane was fabricated as follow: each EDC/NHS collagen
107 membrane was immersed in 0.064% (w/v) EGCG solution at room temperature for 1
108 hr. After that, the EGCG-EDC/NHS collagen membranes were rinsed three times in
109 deionized water and freeze dried overnight. The pure EDC/NHS collagen membranes
110 were also processed under the same protocol except for immersion.

111 **2.2 Surface morphology**

112 The morphologies of EDC/NHS collagen membranes and EGCG modified collagen
113 membranes were characterized by Scanning electron microscope (SEM, S-800,
114 HITACHI, Tokyo, Japan) with an accelerating voltage of 25 kV. The discs were
115 coated with an ultrathin layer (300 Å) of Au/Pt in an ion sputter (E1010, HITACHI,
116 Tokyo, Japan) to achieve enough electrical conductivity.

117 **2.3 Mechanical and chemical properties**

118 a. Mechanical properties measurement

119 To investigate the ultimate stress (US), ultimate elongation (UE) and Young's
120 modulus (YM) of the membranes, each sample (10mm×20mm) was attached to an
121 electronic universal testing machine (SHIMADZU, AG-IC 50 KN, Japan). Five
122 samples were measured for each kind of membranes. Each sample was strained at a
123 rate of 15mm/min at room temperature. When operating differential scanning
124 calorimeter (DSC) measurement, samples in size of 10mm×20mm (~6.71 mg) were
125 encapsulated in aluminum pan, then heated from 25 to 500 °C at a rate of 10 °C/min
126 under nitrogen atmosphere. Thermo-grams were obtained by the Netzsch Proteus
127 analysis software, and thermal denaturation was recorded as the typical peak.

128 b. Chemical properties measurement

129 A Fourier transform infrared spectroscopy (FTIR) spectrophotometer (Spectrum One,
130 PerkinElmer, Inc., Waltham) was employed to measure the FTIR spectra of the
131 samples, the spectra of which were obtained at room temperature at the average of 32
132 scans in the range of 400 – 4000 cm⁻¹.

133 **2.4 Cell viability**

134 The cell viability was examined using the mouse macrophage cell line Raw 264.7
135 obtained from the American Type Culture Collection (Rockville, MD, USA). Staining
136 of Cell Counting Kit-8 (CCK-8, Dojindo Laboratories, Kumamoto, Japan) and
137 Calcein AM/Hoechst were both conducted, but for different time periods. For CCK-8,

138 membranes were processed into 10mm×10mm in the clean bench, then placed in
139 48-well plates and seeded with Raw 264.7 cell at a density of 10^4 /well. 10% CCK-8
140 solution would be added to each well. Cells were then co-cultured for 10, 20, 40, 60,
141 120, 240, 360 min and 1 day, respectively, with RPMI (Gibco, Thermo, USA)
142 supplemented with 10% FBS (Gibco, Thermo, USA). Then plates would be incubated
143 at 37 °C for another 3.5 hr. After incubation, the OD value at 450 nm was measured to
144 determine the cell viability through a micro-plate reader (Multiskan, Thermo, USA).
145 As for staining of Calcein AM/Hoechst, cells were cultured for 5 days on the dishes
146 then incubated with 1μM Calcein AM (diluted from a 1mM stock solution of CAM in
147 dimethyl sulfoxide, Dojindo Laboratories, Kumamoto, Japan) and 100 μL RPMI for
148 30 mins in the incubator. The dishes were then washed three times by 1×PBS and
149 stained with 100μL Hoechst 33258 working fluid (diluted from a 1mL stock solution
150 in distilled water, KeyGen, China) for 10 mins in the incubator. At last, washed the
151 dish for three times by 1×PBS and analyzed with an Inverted Ti-E microscope
152 (Nikon).

153 **2.5 Cell adhesion**

154 SEM images were taken to preliminary estimate cell adhesion after culturing on
155 EDC/NHS-Col and 0.064% EGCG-EDC/NHS-Col for 10, 20, 40 and 480 min, with
156 processed as mentioned in 2.2. The expressions of integrin beta 1, 2, 3 in Raw 264.7

157 cells after culturing on blank wells, EDC/NHS-Col and 0.064%
158 EGCG-EDC/NHS-Col for 10 mins were further evaluated by RNA isolation, cDNA
159 synthesis, and RT-qPCR. Cells cultured on different surfaces were collected after
160 incubating with 0.05% trypsin-EDTA (Gibco, Thermo, USA) for 5 mins and
161 homogenized in 1-ml Trizol Reagent (Tianjian, Beijing, China). Total RNA was
162 reverse-transcribed using mRNA Selective PCR kit (TaKaRa Bio-Clontech). Mouse
163 integrin beta 1, 2 and 3 cDNA were amplified by real-time PCR using the SYBR
164 Green PCR kit (Thermo Scientific, Braunschweig, Germany). The primer sequences
165 used for the real-time PCR were listed in **Table 1**.

166 **2.6 Surgical Procedures**

167 The protocol of the present experiment was approved by Institution Review Board of
168 West China Hospital of Stomatology (No.WCHSIRB-D-2017-097). Male C57BL/6,
169 6~7 weeks of age, were adaptively fed for 3 days after purchasing. After
170 anaesthetization by chloral hydrate, the surgical area on the back was shaved and
171 aseptically prepared. Three parallel sagittal incisions were made in the dorsal skin and
172 subcutaneous pockets were prepared for membrane implantation. The two kinds of
173 membranes were prepared beforehand into 3mm×3mm size in the clean bench.
174 EDC/NHS collagen membranes and EGCG-EDC/NHS collagen membranes were
175 implanted into the pockets respectively. The control group underwent a sham

176 procedure. Afterwards, all the incisions were sutured. These mice were kept in a
177 professional experimental animal room and fed with a standard laboratory diet. After
178 recovering for 0 (12hr), 1, and 3 days, they were sacrificed by cervical dislocation.
179 The membranes and the skins covering the materials were harvested together (equal
180 areas around the suture were harvested in the control groups) and immediately fixed
181 with 4% paraformaldehyde (Solarbio, Beijing, China) for at least 24hr.

182 **2.7 H & E staining**

183 The fixed samples were sliced into 3- μ m thick sections after embedding in paraffin
184 for the following H & E staining and immunofluorescence assay. For H & E staining,
185 the sections were incubated at 65 $^{\circ}$ C for 4hr for deparaffinization and processed as
186 follow:

- 187 a. Dhydration with ethanol;
- 188 b. Stain with hematoxylin for 5 mins and differentiate in 1% hydrochloric acid
189 alcohol for 2 s ;
- 190 c. Incubate in 0.2% ammonia water for 2 mins and stain with eosin for 1 min;
- 191 d. Gradual dehydration through 95% ethanol, then clear and mount the sections with
192 neutral resin. The sections were observed with light microscopy (Olympus, Tokyo,
193 Japan) and scanned with Digital Slide Scanning System (PRECICE, Beijing,
194 China).

195 **2.8 Promotion of revascularization**

196 3 days after implantation, tissue was harvested and prepared as sections. Then,
197 sections would be fixed with 2% paraformaldehyde PBS for 24 hours (pH=7.4) and
198 later washed by PBS for 3 times, which followed by soaking in 1% bovine serum
199 albumin (BSA) PBS that contained 1% Triton X-100 for 1 hour. Eventually, incubated
200 the sections in 1% Tween 20 for 10 mins, and washed twice in PBS for 5 mins. The
201 sections were then stained with nucleus marker Hoechst, endothelial cell marker
202 CD31 and adventitial fibroblast marker α -SMA to visualized specific components in
203 the fluorescent images.

204 **2.9 Statistical Analysis**

205 Data are presented as mean + standard deviation. Statistical computation was
206 performed in GraphPad Prism 5.0 (GraphPad Software, San Diego, CA, USA) and
207 statistical significance was analyzed using analysis of variance followed by Tukey's
208 multiple comparison tests. Semi-quantitative data of immunofluorescence staining
209 and HE staining that did not follow a normal distribution were further analyzed with
210 Mann-Whitney *U* test. Unless otherwise noted, $p < 0.05$ was considered statistically
211 significant.

212 **3. Results**

213 **3.1 Surface morphology**

214 As shown in representative SEM images (**Fig. 2**), the surface morphology of
 215 EDC/NHS collagen membranes exhibited a rough, disordered outlook, with fibers
 216 randomly distributed. After treating with 0.064% EGCG, there were no notable
 217 changes on the outlooks, while the arrangement of fibers appeared more ordered and
 218 intact. In addition, we also found that smaller fiber branches extend from the
 219 backbone when compared with those without EGCG treatment. These might be due to
 220 the loading of EGCG hydrogen bonds formation between EGCG molecules and
 221 collagen fibers.

222
 223 **Fig. 2.** SEM images of EDC/NHS collagen membrane and 0.064% EGCG loaded
 224 EDC/NHS collagen membrane.

225 3.2 Mechanical and chemical properties

226 To examine the strength, stiffness and elasticity of the membranes, measurement of
 227 US, UE and YM were carried out and the corresponding volumes were written in
 228 **Table 2.** As US seemed relatively constant between the control and EGCG group,

both UE and YM showed different trends. The modification of 0.064% EGCG strengthened the UE volume of collagen membranes, whereas weakened the YM volume (**Fig. 3a**). Also, there were no statistical difference between membranes with or without EGCG modification in result of DSC measurement (**Fig. 3b**). From results of FTIR spectra and DSC measurement, it could be concluded that chemical properties remain consistent before and after the treatment of 0.064% EGCG. The FTIR spectra indicated that no structure changes had happened to collagen fibers since the absorption peaked at 1235 cm^{-1} (tertiary structure) and 1450 cm^{-1} (pyrrolidine ring vibrations) of EDC/NHS collagen membrane, and 0.064% EGCG-EDC/NHS collagen membrane remained constant. Also, the ratio of $1235\text{ cm}^{-1}/1450\text{ cm}^{-1}$ (**Table 3**) came out to be around 1.00, illustrating that the secondary structure of collagen triple helix remained its integrity in both membranes, which assured the great biological performance of collagen membranes (Figueiró, Góes, Moreira, & Sombra, 2004). Therefore, it could be inferred that EGCG did not affect the physicochemical property of collagen.

Fig. 3. Young's Modulus (a) and DSC statistics (b) of EDC/NHS collagen membrane and 0.064% EGCG-EDC/NHS collagen membrane. NS= no significance.

3.3 Cell Viability

The results of CCK-8 staining showed the cell viability of raw 264.7 cells under pure medium, 0.064% EGCG supplemented medium, EDC/NHS collagen membrane and 0.064% EGCG-EDC/NHS collagen membrane (**Fig. 4a**) from the first few minutes to 1 day. In the first hour, there was no significance between the groups. The improvement of cell viability by EGCG was raised after culturing for 2 hr and the following time points. In order to understand the effect of EGCG on cell viability after culturing for longer time period, Calcein AM/Hoechst staining was conducted on day 5 (**Fig. 4b**). The test results also showed the same trend with more live cells on EGCG-EDC/NHS-Col comparing with EDC/NHS-Col, indicating that the addition of EGCG was conducive to the performance of cell activities.

Fig. 4. CCK-8 results (a) and Calcein AM/Hoechst staining (b) of Raw 264.7 cultured on different condition. Ctrl, standard medium; EGCG, 0.064% EGCG supplemented medium; EDC/NHS-Col, EDC/NHS collagen membrane; EGCG-EDC/NHS-Col, 0.064% EGCG-EDC/NHS collagen membrane. Green, live cells; blue, nucleus. NS= no significance, * $P<0.05$, ** $P<0.01$, *** $P<0.001$, one-way ANOVA with Tukey's multiple comparison test, $n = 3$ in each group.

3.4 Cell adhesion

To observe cell adhesion towards the membrane, SEM was used to generate the morphology of Raw 264.7 cells cultured on membranes in 8 hr (**Fig. 5a&b**). It elucidated that with the modification of EGCG, not only more cells adhered to the

269 surface but also a better spreading condition of cells was detected. Also, more
 270 protrusions could be seen to seize the fibers even at very early incubation, compared
 271 to that without EGCG. Considering integrins, the transmembrane molecules, with
 272 large extracellular domains that are known to play a key role in adhesion between
 273 cells and ECM (Changede & Sheetz, 2017; Tseng et al., 2018), expression levels of
 274 integrin beta 1, 2 and 3 in Raw 264.7 cells were measured. The result showed that
 275 there existed a boost of integrin beta 2 in the EGCG- EDC/NHS group, whereas no
 276 differences appeared in the expression of integrin beta 1 and 3 with the treatment of
 277 0.064% EGCG (**Fig. 5c**). These results suggested that 0.064% EGCG could enhance
 278 the adhesion properties of EDC/NHS collagen membrane at early phases.

279

280 **Fig. 5.** SEM images of Raw 264.7 cells cultured on EDC/NHS and EGCG treated
 281 EDC/NHS collagen membranes under low (a) and high (b) magnification, and the
 282 expression levels of integrin beta 1, 2 and 3, after culturing on tissue culture plate
 283 (TCP), EDC/NHS-Col and EGCG-EDC/NHS-Col for 10 mins (c), respectively. NS=
 284 no significance.

285 3.5 Promotion of revascularization

286 We identified the ability of 0.064% EGCG EDC/NHS-Col to promote
287 revascularization by immunofluorescence staining of nuclei, vascular endothelial cell
288 marker CD31 and adventitial fibroblast marker α -SMA (Manetti et al., 2017). As
289 shown in **Fig. 6a**, more blood vessels were generated in EGCG-EDC/NHS-Col
290 compared to EDC/NHS-Col, meanwhile, as shown in **Fig. 6d**, the results of
291 semi-quantitative analysis of total blood vessel area showed that it was larger in 0.064%
292 EGCG EDC/NHS-Col than that in the EDC/NHS-Col ($p < 0.01$).

293 **3.6 Recruitment of monocyte/macrophage**

294 12 hours after the implantation, there were no visible cells recruited at surgical sites,
295 but with another 12 hours, we could see that around the membrane, a certain number
296 of immune cells were gathered, which was similar on 3-days post implantation (**Fig.**
297 **6c&d**). In addition, semi-quantitative cell counting revealed that in 1- and 3-days post
298 surgeries, 0.064% EGCG-EDC/NHS-Col recruited more monocytes/macrophages,
299 while EDC/NHS-Col was about one-third of the number of the experimental group
300 (**Fig. 6e**).

Fig. 6. Results of subcutaneous implantation. Immunofluorescence staining of α SMA (green), CD31 (red) and Hoechst (blue) in subcutaneous implantation samples of EDC/NHS-Col and EGCG-EDC/NHS-Col, control group refers to normal skin (a); semi-quantitative analysis of total blood vessel area was calculated in each group (d). Recruitment of monocyte/macrophage after subcutaneous implantation of EDC/NHS collagen membrane and EGCG-EDC/NHS collagen membrane, control group underwent a sham procedure. HE staining of subcutaneous tissue (b&c) and cell counting of monocyte/macrophage (e) in NHS/EDC-Col and EGCG-EDC/NHS-Col were conducted on day 0, 1, and 3 post implantations. Arrows indicate material (b) and monocyte/macrophage (c). Statistical significance was analyzed using analysis of variance followed by Tukey's multiple comparison tests and Mann-Whitney *U* test ($n = 5$). Data are presented as mean + standard deviation. * $P < 0.05$, *** $P < 0.001$.

4. Discussion

To reconstruct alveolar bone deficiency, the application of biomaterials and certain surgery are on account of its morphology and the severity of horizontal/ vertical bone loss. When performing GBR, bone defect less than 6 mm is a prerequisite for desirable outcome, whereas the complex case that is combined with vertical and horizontal bone defect ≤ 4 mm, it is recommended to use crosslinked absorbable membrane or non-absorbable membrane with bone filler to create appropriate repair conditions (Tolstunov, Hamrick, Broumand, Shilo, & Rachmiel, 2019). In addition, crosslinked membranes are more osteoinductive, with more bone marrow-multipotent stromal cells attachment to the crosslinked membranes, better ALP activity, and calcium deposition were observed compared with the non-crosslinked one (El-Jawhari, Moisley, Jones, & Giannoudis, 2019). According to previous studies, the use of EDC as crosslinker could not only prolong the integrity of the membrane, but also avoid

327 severe FBR, lack of vascularization in the early stage of healing and poor integration,
 328 which are the fatal flaws of traditional cross-linking agents (Park et al., 2015). The
 329 addition of NHS would improve EDC-mediated crosslinking, stabilize active
 330 intermediates, and reduce side products for subsequent reactions (Grabarek & Gergely,
 331 1990). However, the present EDC/NHS crosslinked collagen membrane lacks the
 332 ability to regulate immune responses and induce osteoblast-related cell behavior.
 333 Regarding cell behavior, EGCG has shown the ability to complement these two
 334 aspects in our previous research as mentioned in the introduction. Thus, we attempted
 335 to modify to EDC/NHS crosslinked collagen membrane with 0.064% EGCG. After
 336 characterizing the material, results show that the backbone of collagen remains intact
 337 and the strength of membranes is barely altered, whereas the stiffness is moderately
 338 enhanced, though elasticity is slightly weakened. These not only ensure that the
 339 membrane will not be too supple to tightly cover the substitutes, supporting bone
 340 formation, but also verify that the chemical structure related to the biological activity
 341 of collagen has not been destroyed, though the definite clinical effect needs
 342 verification. Over the past decade, the ability of biomaterials to promote tissue
 343 regeneration by regulating immune cells in advance has been confirmed, the
 344 composition, physical and chemical properties, and surface morphology of which are
 345 the critical factors that affect the foreign body reaction (FBR) after implantation. As

one of the dominant immune cells in the FBR, macrophages can acutely polarize into different phenotypes according to the microenvironment created by the implant and direct the accumulated cells' behaviors that strongly involve in tissue reconstruction (Chu, Deng, Sun, Qu, & Man, 2017; Xie et al., 2020). The arrangement and diameter of the fibers can significantly affect the behavior of macrophages. Anisotropic membranes with thicker fibers have an increased tendency to oxidative degradation, compared with the thinner and isotropic one (Wissing et al., 2019), more macrophages adherence on the align compared with the random and the smaller fibers also have been proved with better biocompatibility as thinner fibrous capsule and abundant volume of blood vessel formation (Saino et al., 2011). In this article, we found that the surface morphology of EGCG-EDC/NHS-Col has been altered with smaller fiber branches extended from the backbone and the arrangement became more coherent, which may account for the cell viability and adherence. Under the electron microscope, the viability of RAW 264.7 on EGCG-EDC/NHS-Col is significantly higher than any other groups at all detection points during 2-24 hours after implantation. Not only did more macrophages adhere to membrane with the treatment of EGCG, but the adhered macrophages were activated at an early stage (20min) with many protrusions, and which is also confirmed by PCR detection. Also, more monocyte/macrophage recruitment could be seen on EGCG-EDC/NHS-Col in the *in*

365 *vivo* subcutaneous implantation. As researchers have found that the onset of
366 neovascularization greatly depends on macrophage and its coherent phenotypic switch
367 (Spiller et al., 2014; Spiller, Freytes, & Vunjak-Novakovic, 2015), we hypothesize the
368 promising angiogenesis is result from the recruitment of macrophages which cannot
369 be excluded considering the microstructure of EGCG-EDC/NHS-Col. Of note, in our
370 previous study, the modification of EGCG was highly competent at promoting
371 vascularization that involved the secretion of M2-related chemokines (Chu et al.,
372 2018). The formation of blood vessel could offer nutrient, stem cells and oxygen
373 supply and waste discharge, vastly improving the regenerative response. Therefore,
374 our efforts are directed at macrophages and the outcome of vascularization as primary
375 study towards the developed EGCG modified EDC/NHS collagen membrane. And
376 our results showed that the modification of EGCG is beneficial for cell viability,
377 adhesion and vessel formation in both *in vitro* RAW 264.7 culture experiment and in
378 *vivo* subcutaneous implantation. The great biocompatibility of EGCG modified
379 EDC/NHS collagen guided bone regeneration membrane is stated without
380 compromising the advantages of collagen itself. Furthermore, our results
381 demonstrated the modified membranes could significantly affect the attachment of
382 macrophages and enhance its viability both *in vivo* and *in vitro*, which might be
383 related to the formation of vessels. However, the phenotypes of macrophages and

mechanisms of angiogenesis need further investigation. In short, we develop a biomaterial that can promote the early recruitment of macrophages and the formation of blood vessels, possessing great potential for bone regeneration in the field of implant dentistry.

5. Conclusion

In conclusion, with the modification of EGCG, EDC/NHS collagen guided bone regeneration membrane can better promote cell adhesion and improve cell viability, which is confirmed in our experiments that living cells attach to it and the expression of adhesion-related integrin is indeed increased. In addition, there was a statistically significant difference in angiogenesis after membrane implantation. The benefits mentioned above do not exclude the presence of smaller collagen fibers, but this different microstructure does not damage the chemical structure of the collagen itself, though the specific effect needs further exploration.
