21 **Summary**

22

23 The elaborate movement of the vertebrate body is supported by the precise connection of
 24 muscle, tendon and bone. Each of the >600 distinct skeletal muscles in the human body
 25 has unique attachment sites; however, the mechanism through which muscles are
 26 reproducibly attached to designated partner tendons during embryonic development is
 27 incompletely understood. We herein show that Screlaxis-positive tendon cells have an
 28 essential role in correct muscle attachment in mouse embryos. Specific ablation of
 29 Screlaxis-positive cells resulted in dislocation of muscle attachment sites and abnormal
 30 muscle bundle morphology. Step-by-step observation of myogenic cell lineage revealed
 31 that post-fusion myofibers, but not migrating myoblasts, require tendon cells for their
 32 morphology. Furthermore, muscles could change their attachment site, even after the
 33 formation of the insertion. Our study demonstrated an essential role of tendon cells in the
 34 reproducibility and plasticity of skeletal muscle patterning, in turn revealing a novel
 35 tissue-tissue interaction in musculoskeletal morphogenesis.

43 **Introduction**

44 The musculoskeletal system is a complex multi-tissue system that consists of muscle,
 45 tendon and bone, as well as associating connective tissues. Elaborate body movements of
 46 vertebrate are supported by the precise shape, position and functional connections of
 47 these components. While the differentiation process of each component has been well
 48 studied (Asahara, Inui, & Lotz, 2017; Buckingham & Rigby, 2014; Kozhemyakina,
 49 Lassar, & Zelzer, 2015), their tissue integration process remain largely unexplored.
 50 Hundreds of skeletal muscles exist in the mammalian body; however, most are derived
 51 from the somites. Myogenic progenitor cells migrate long distances to destinations such
 52 as the limbs, form a precise bundle shape, and attach with appropriate tendons and bones
 53 during embryonic development (Buckingham et al., 2003; Comai & Tajbakhsh, 2014). It
 54 is well known that the migration of myogenic progenitor cells from somite to limb bud is
 55 guided by secreted cues such as HGF/SF or SDF-1 (Dietrich et al., 1999; Griffin, Apponi,
 56 Long, & Pavlath, 2010). However, mechanisms that regulate tissue integration between
 57 post-migration muscle cells and tendons and bones are not fully understood (Kardon,
 58 2011; Schweitzer, Zelzer, & Volk, 2010). Considering the distinct cellular origin (i.e.,

59 muscles from the somites and tendons from the lateral plate) and large number of
60 integrations to be formed in limited time and space, it is reasonable to assume that the
61 local tissue-tissue interactions take place between myogenic progenitor cells and the
62 surrounding cell/tissue. Indeed, several factors, including transcription factors, ECM,
63 muscle connective tissue cells (MCTs) are reported to regulate the patterning of
64 post-migrating myogenic cells in vertebrate limbs (Besse et al., 2020; Hasson et al., 2010;
65 Helmbacher & Stricker, 2020; Kardon, Harfe, & Tabin, 2003; Kutchuk et al., 2015;
66 Rodriguez-Guzman, Montero, Santesteban, Gañan, Macias, & Hurle, 2007b; Swinehart,
67 Schlientz, Quintanilla, Mortlock, & Welik, 2013). However, whether tendon cells, the
68 intrinsic partner of skeletal muscles, have any role in instructing the muscle shape and
69 patterning in mammals is unclear. To examine the role of tendon cells in the regulation of
70 muscle patterning, we took a simple approach of lineage-specific cell ablation and reduced
71 the tendon cells in embryos. As a result, we found that muscle attachment patterns are
72 significantly altered in the embryo with reduced tendon cells. Our results indicate that
73 Scx-positive tendon cells have an important instructive role in spatially precise muscle
74 attachment patterns, and are in turn essential for reproducible and robust musculoskeletal

75 morphogenesis.

76

77 **Results and Discussion**

78 **ScxCre mediated tendon ablation**

79 To induce tendon cell-specific cell death, we mated a *ScxCre-L* Tg mouse
80 (Sugimoto, Takimoto, Hiraki, & Shukunami, 2013b) with a *Rosa26-LSL-DTA* mouse
81 (Voehringer, Liang, & Locksley, 2008) (Fig. 1A). As a result, we observed
82 TUNEL-positive cells in tendon tissue of the tail and limb of Cre+/DTA+ embryo at
83 E15.5, but not in control embryos (Fig. 1C, E arrowheads, Fig. S1 A-D). H&E staining of
84 consecutive sections showed tissue ablation in the tail tendon tissue of Cre+/DTA+
85 embryo (Fig. 1B, D arrowheads). Cre and DTA dependent TUNEL-positive cells were
86 observed as early as E12.5 in the forelimb, shoulder, intervertebral mesenchyme, or tail
87 (Fig. S1 E-P). These results suggest that we could successfully induce cell death
88 specifically in the tendon cells, from their early stage of differentiation. Hereafter, in this
89 manuscript, we designate the mice with *ScxCre-L* Tg and *Rosa26-LSL-DTA* alleles as
90 “*Scx-DTA*” mice.

91 Next, we examined the tendon tissue of *Scx-DTA* embryo with the *Mkx-Venus*
92 knock-in allele (Ito et al., 2010). As shown in Fig. 1F and J, the long tendons in the

93 zeugopod were reduced in E17.5 *Scx-DTA* embryo. The limb sections showed that the
 94 flexor digitorum profundus (FDP) tendon (Fig. 1G, K) and flexor digitorum sublimis
 95 (FDS) tendon (Fig. 1H, L) in the autopod, extensor carpi radialis tendons, extensor
 96 digitorum communis (EDC) tendons, or the palmaris longus tendon (Fig. 1I, M) in the
 97 zeugopod were greatly reduced in *Scx-DTA* embryos. The reduction of tendon tissue in
 98 other parts of the body, such as the Achilles tendon (Fig. 1N, R) or tail tendon (Fig. 1O, S)
 99 was also apparent. Furthermore, ligamentous tissue, such as the cruciate and patella
 100 ligaments were diminished (Fig. 1P, T) and the outer annulus fibrosus of the
 101 intervertebral disc was also reduced (Fig. 1Q, U). In sum, these results illustrated that our
 102 approach reduced the tendon and ligament tissues from the developing embryo, albeit not
 103 completely. The reductions of tendon tissue have been reported in mice with the knockout
 104 of tendon transcription factors (TFs), such as *Scleraxis* (*Scx*), *Mohawk* (*Mkx*) or *Egr1*
 105 (Guerquin et al., 2013; Ito et al., 2010; Murchison et al., 2007). The degree of
 106 tendon/ligament reduction in *Scx-DTA* mice was as severe as or even more severe than
 107 those observed in these TF mutants. Namely, the cell death was observed as early as
 108 E12.5 in *Scx-DTA* embryo, which is earlier than the reported tendon reduction in TF

109 mutants. In addition, while the tendon reduction was seen mainly in the long tendons in
 110 TF mutants, most of tendon and ligament tissues were reduced in *Scx-DTA* embryos. The
 111 Incomplete loss of tendon tissue was probably due to the penetrance of Cre
 112 activity(Comai, Sambasivan, Gopalakrishnan, & Tajbakhsh, 2014), or continuous
 113 recruitment of *Scx*-positive tendon cells from limb mesenchyme population (Huang et al.,
 114 2019; Shwartz, Viukov, Krief, & Zelzer, 2016). As tendon cell death occurs in a period
 115 that overlaps the individuation of tendon from anlage (Huang et al., 2015), this could also
 116 have an impact on tendon patterning. Indeed, the numbers of FDS or EDC tendons were
 117 reduced and outline of each of the tendons were indistinct in the *Scx-DTA* embryo (Fig.
 118 1H, I, L, M)

119 We found that *Scx-DTA* pups died soon after birth (Fig. 1V, W). *Scx-DTA*
 120 embryo showed a defect in diaphragm (described below), which could cause an
 121 insufficient respiratory function in newborn *Scx-DTA* pups. In addition, as *Scx* is
 122 expressed also in non-tendon/ligament tissues such as the patella, rib cage, and bone
 123 ridges (Blitz, Sharir, Akiyama, & Zelzer, 2013; Sugimoto, Takimoto, Akiyama, Kist,
 124 Scherer, et al., 2013a), these *Scx*-positive skeletal elements are also reduced or lost in

125 *Scx-DTA* embryos (Fig. 1X, Fig. S2). The loss of rib cage could also cause respiratory
126 problems. Thus, in the present study, we only focused on embryonic development. The
127 effects of skeletal abnormality are also discussed (see below).

128

129 **Muscle patterning was altered in tendon-ablated embryos**

130 Next, we examined whether the patterning (i.e., shape or attachment) of
131 skeletal muscles was altered in *Scx-DTA* embryos. First, we applied whole-mount
132 immunohistochemistry with a myosin heavy chain (MHC) antibody for the analysis of
133 the forelimb of P0 pups. In control limbs, the muscles were located between their regular
134 attachment sites (origin and insertion); for example, the deltoid muscle originates from
135 spine of the scapula and inserts into deltoid tuberosity (Fig. 2B, C blue arrowhead). In
136 contrast, muscles in *Scx-DTA* mice showed changes in their attachment sites; for example,
137 the insertion site of the deltoid muscle changed to the shoulder joint (Fig. 2F, G red
138 arrowhead). The shapes/attachments of muscles in the zeugopod also changed, for
139 example the extensor carpi ulnaris (ECU) and extensor digiti quarti/quinti (EDQ)
140 muscles were clearly separated in the control limb (Fig. 2D arrowheads), but they were

141 fused into a single muscle bundle in the *Scx-DTA* limb (Fig. 2H arrowhead). The extensor
142 pollicis muscles, which are normally covered by superficial muscles, became visible (Fig.
143 2D, H arrows). Of note, despite their morphological change, most of the muscles in the
144 zeugopod attached with tendons at their distal end.

145 In sections of E18.5 forelimbs, muscles in the metacarpal position were grossly normal
146 (Fig. 2I, L, O). However, FDS muscles were found in the wrist position of the *Scx-DTA*
147 limb, where muscle was not observed in control embryos (Fig. 2J, M, O). Conversely,
148 FDS muscles were missing from their normal position in the zeugopod of *Scx-DTA* mice
149 (Fig. 2K, N, O arrowheads). Interestingly, similar distal dislocation of FDS muscle has
150 been reported in *Scx*-knockout mice (Huang et al., 2013), indicating that this change in
151 muscle position is due to the reduction of FDS and FDP tendons. In addition, the
152 arrangement of the extensor carpi (longus/Brevis) and FDP muscles was changed (Fig.
153 2K, N arrows). On the other hand, muscles in the hindlimb generally showed a normal
154 attachment pattern (Fig. S3).

155 Altered attachment sites were also observed in other muscles, especially in
156 muscles connecting to the body trunk and limbs. For example, the pectoral muscles

157 originate from the sternum and insert into the deltoid tuberosity in control embryos (Fig.
158 2P, P' arrowhead); however, the insertion sites of these muscles were distally dislocated
159 toward the elbow joint in *Scx-DTA* mice (Fig. 2R, R' arrowhead). In a severe case, the
160 pectoral minor muscle separated into two bundles (Fig. 2R, R' arrows). Similarly, in
161 *Scx-DTA* mice, the insertion site of the gluteus maximus muscle, which normally
162 originates from the ilium and inserts into the gluteus tuberosity (Fig. 2Q, Q' arrowheads)
163 changed distally, toward the knee joint (Fig. 2S, S'). The organization of muscles in the
164 trunk, such as the rectus abdominis, was also changed in *Scx-DTA* mice (Fig. 2T, V). In
165 the diaphragm, the width of the central tendon was greatly reduced (Fig. 2U, W arrows)
166 and the orientation of associated muscle fibers was changed (Fig. 2U, W arrowheads). In
167 sum, the organization of skeletal muscles of many body parts was changed in *Scx-DTA*
168 mice, suggesting that tendon cells are necessary for skeletal muscle to form a precise
169 shape and attachment in the correct position. The role of tendon tissue in muscle
170 patterning has been shown indirectly in other vertebrate species; for example, the surgical
171 removal of the tendon primordia resulted in ectopic extension of the muscle into the knee
172 joint in chicken embryos (Kardon, 1998). *Scx*-knockout zebrafish embryos showed

173 abnormal muscle patterning (Kague et al., 2019). In mammals, muscle-tendon interaction
174 has been studied in the opposite direction and the requirement of muscle cells for tendon
175 formation has been reported (Brent, Braun, & Tabin, 2005; Pryce et al., 2009). Our results
176 represent the first evidence that directly points to the importance of tendon cells in muscle
177 patterning in mammalian embryos. Muscle patterning in limbs also depends on
178 LPM-derived mesenchyme cells or muscle connective tissue (MCT) cells that are closely
179 associated with the myogenic lineage (Hasson et al., 2010; Kardon et al., 2003;
180 Vallecillo-García et al., 2017). As such, we considered whether MCT is affected in
181 *Scx-DTA* mice. As shown in Fig. S4, the expression levels of MCT marker genes were
182 unaltered in *Scx-DTA* mice, while tendon marker genes were clearly reduced. Also, *Cre*
183 expression in *ScxCre-L* Tg is restricted in tendon cells and not detected in MCTs
184 (Sugimoto, Takimoto, Hiraki, & Shukunami, 2013b). We concluded that the phenotype
185 seen in *Scx-DTA* mice is primarily due to the loss of tendon cells.

186

187 Myofibers but not myoblasts require tendon cells for patterning

188 Next, to elucidate the stage at which tendon-muscle interaction takes place, we

189 monitored the location and shape of the myogenic cell lineage in a step-by-step manner,
190 along with their migration and differentiation. First, we found that *pax3*-positive
191 myogenic progenitor cells were induced in the somite and migrated normally into the
192 limb buds at E11.5 (Fig.3A, D arrowheads). *Myogenin*-positive myoblast positions were
193 grossly normal at E12.5 or E13.5 (Fig.3B, C, E, F), suggesting that myoblast segregation
194 occurred in similar manner in control and *Scx-DTA* mice. Furthermore, *myh3*-positive
195 myofibers were observed in same position in *Scx-DTA* and control embryos at E12.5 (Fig.
196 3G, J), indicating that myofiber differentiation is not dependent on tendon cells. Of note,
197 we found that the *myh3* signal became significantly high at the distal/proximal ends of
198 myofibers from E13.5 (Fig. 3H, I arrowheads). By comparing the expression of *myh3* and
199 a mature tendon marker, *tenomodulin* (*Tnmd*) (Shukunami, Oshima, & Hiraki, 2001;
200 Shukunami et al., 2018), we noted that this high *myh3* expression marks the boundary of
201 muscle and tendon (Fig. S3). We therefore interpreted the *myh3* high region as surrogate
202 of the muscle-tendon boundary. The shape of *myh3*-positive muscle bundles clearly
203 differed between *Scx-DTA* and control embryos at E13.5 (Fig.3H, K). While the EDC
204 muscle in the control embryo formed a sharp boundary at its distal tip (Fig. 3H), the distal

205 tip of EDC in *Scx-DTA* embryo remained loose shape without the clear boundary
206 formation (Fig. 3K). Moreover, while the ECU and EDQ muscle bundles in control
207 embryos were clearly separated and formed two distal boundaries (Fig. 3H blue
208 arrowheads), those muscles did not separate or form normal distal boundaries in *Scx-DTA*
209 embryos (Fig. 3K red arrowheads). The muscle patterning defects became more apparent
210 in E14.5, where EDC/EDQ/ECU muscles could not be distinguished (Fig. 3I, L).
211 Immunohistochemistry with MHC antibodies confirmed that the shapes of MHC-positive
212 muscle bundles became loose in *Scx-DTA* embryos (Fig. 3M-P) and the insertion sites of
213 several muscles, including the triceps (Fig. 3 M, O) and deltoid muscles (Fig. 3N, P),
214 were dislocated. These results indicate that tendon cells are dispensable for the migration,
215 initial segregation, or differentiation of myofibers, but are required for the formation of
216 proper muscle bundle morphologies and the precise location of the attachment site.
217 Previous studies showed that tendon anlagen are induced in muscles-less limbs normally;
218 however the maturation of tendons requires muscles (Brent et al., 2005; Huang et al.,
219 2015; Pryce et al., 2009). Our results together with those studies, indicate that muscle and
220 tendon anlage are induced independently, but their connection and maturation is mutually

221 dependent. The patterning of limb muscle is regulated by surrounding tissues at various
222 time point (Helmbacher & Stricker, 2020). While the loss of the *Tbx5* in *Prx1*-positive
223 mesenchyme altered the patterning of tendon and muscle from E12.5 (Hasson et al.,
224 2010), *Osr2Cre* dependent MCT ablation affected the patterning of *MyoD*-positive
225 muscle clusters at E13.0 (Besse et al., 2020). Our results implied that the role of tendon
226 cells, which is to finalize the muscle bundle position and attachment, is played later in
227 comparison to other connective tissues. It is likely that multiple inputs from surrounding
228 cells regulate limb muscle patterning sequentially and in an overlapping manner.

229

230 **Skeletal malformation or cell death are not the cause of muscle patterning defects**

231 As *Scx* is also expressed in some skeletal elements, such as the rib and patella
232 (Sugimoto, Takimoto, Hiraki, & Shukunami, 2013b), *Scx-DTA* mice showed several
233 skeletal malformations, including loss of the rib cage or deltoid tuberosity (Fig. 1X, Fig.
234 S2). To exclude the possibility that these skeletal malformation caused the muscle
235 patterning defects, we examined the attachment pattern in embryos in which skeletal
236 defects similar to those of *Scx-DTA* mice were reported (Braun, Rudnicki, Arnold, &

237 Jaenisch, 1992; Kist et al., 2002). *Sox9* heterozygous (*Sox9^{fl/-}*) embryos which lack the
238 deltoid tuberosity were generated by mating *Sox9^{fllox/flox}* and *Meox2-Cre* mice (Fig. S6B,
239 D). Heterozygous *Myf5^{Cre/+}* knock-in mice were intercrossed to generate homozygous
240 *Myf5^{Cre/Cre}* embryos, which resulted in rib cage malformation due to the loss of the Myf5
241 protein (Fig. S5F, H). In both cases the insertion sites of the pectoralis major muscles
242 were not altered, despite the skeletal defects (Fig. S6 A, C, E, G). These results imply that
243 the loss of skeletal elements is not the major cause of the muscle patterning defect seen in
244 *Scx-DTA* mice. A previous study on the role of transcription factor *Lmx1b* also showed
245 that the change of skeletal elements alone does not cause the muscle patterning change.
246 Deletion of *Lmx1b* in a *Prx1*-positive lineage altered the dorso-ventral polarity of the
247 whole limb, including the bone, tendon and muscle; however the loss of *Lmx1b* in the
248 *Sox9*-positive lineage resulted in the change of bone, but not tendon or muscle polarity
249 (Li, Qiu, Watson, Schweitzer, & Johnson, 2010).

250 Programmed cell death is one of the important driving forces of morphogenesis,
251 such as digit formation or muscle belly segregation (Guha, Gomes, Kobayashi, Pestell, &
252 Kessler, 2002; Rodriguez-Guzman, Montero, Santesteban, Gañan, Macias, & Hurle,

2007a). As such, the cell death induced in *Scx-DTA* mice could directly or indirectly affect the muscle attachment pattern. To explore this possibility, we examined the muscle patterning of the embryo where cell death is induced in muscle tissue by the *Myf5-Cre* dependent expression of DTA (*Myf5^{Cre/+}:Rosa26-LSL-DTA*, hereafter “*Myf5-DTA*”). In *Myf5-DTA* embryos, despite a severe reduction of muscle mass, the remaining pectoralis major muscle was correctly inserted into the deltoid tuberosity (Fig. S6I, J). This result indicated that excess cell death in the tissue does not necessarily cause muscle patterning defects.

261

262 **Dynamic change in muscle patterning after myofiber formation**

263 The results shown above implied that the skeletal muscles define their attachment sites after myofiber formation (e.g., Fig. 3 G-L). We then asked if the position of muscle could be altered after the formation of insertion, which may provide skeletal muscle patterning further plasticity and robustness. To examine this point, we observed the position and insertion of gluteus maximus muscle at two time points E14.5 and E17.5. As shown in Fig. 4A and D, the distal tips of the gluteus maximus are located at the

269 middle of the femur (i.e., the gluteus tuberosity) at E14.5 in both WT and *Scx-DTA* mice
 270 (Fig. 4A, D). A detailed section analysis confirmed that the gluteus maximus muscles
 271 formed insertions with gluteus tuberosity through tendon cells at this stage, although the
 272 tendon cells were reduced in *Scx-DTA* mice (Fig. 4B, C, E, F). As embryonic
 273 development proceeds, the junction of the gluteus maximus muscle/tendon matured and
 274 was firmly inserted into the gluteus tuberosity at E17.5 (Fig. 4G-I). On the other hand, the
 275 tip of gluteus maximus muscle of *Scx-DTA* mice was distally dislocated while most of the
 276 tendon and insertion into the gluteus tuberosity was lost by this stage (Fig. 4J-L). These
 277 results imply that the skeletal muscle is able to reposition its attachment site according to
 278 environmental changes, even after myofiber differentiation or the formation of initial
 279 attachment. Recent studies also reported the post-natal elongation or post-fusion
 280 repositioning of muscles (Gu et al., 2016; Huang et al., 2013), indicating that the
 281 plasticity of muscle positioning is higher than generally considered. We assume that this
 282 interaction between skeletal muscle and tendon provides musculoskeletal morphogenesis
 283 reproducibility and robustness to resist environmental or genetic perturbations.

284 The molecular mechanism underlying this muscle-tendon interaction remains

285 to be explored. In *Scx-DTA* mice, muscles in the zeugopod (i.e., the EDC/EDQ/ECU
286 muscles) fused and attached to the remaining tendons at their distal end (Fig. 2H). The
287 insertion sites of the muscles in the girdle (i.e., the pectoral and gluteus muscles)
288 dislocated toward the joint regions, such as the shoulder, elbow or knee (Fig. 2, Fig. S7B).
289 The remaining tendon cells were relatively abundant in the joint area of *Scx-DTA*
290 embryos (Fig. 1F, J, Fig. S7A), probably due to the initial amount and continuous cell
291 recruitment/differentiation from the *Scx*-negative cell population (Huang et al., 2019;
292 Schwartz et al., 2016). The fact that muscle did not attach randomly to nearby bone but
293 changed its morphology toward the distal tendon tissue implied a hypothesis that
294 diffusible molecule(s) secreted from tendon cells could attract myofibers. Indeed, recent
295 studies reported the involvement of retinoic acid in the formation of the extraocular
296 functional unit (Comai et al., 2020), and FGF or BMP signaling were active at the
297 interface of the embryonic tendon and muscle (Eloy-Trinquet, Wang, Edom-Vovard, &
298 Duprez, 2009; Wang et al., 2010). However, cell adhesion molecule (Hasson et al., 2010)
299 or ECM (Kutchuk et al., 2015) can also play parallel roles. Moreover, LPM-derived cells
300 were recently suggested to convert their cell fate to the myogenic lineage at the tip of

301 muscles and to regulate muscle patterning (de Lima et al., 2020). Clearly more studies are
302 required to fully understand the molecular and cellular mechanisms of precise skeletal
303 muscle patterning. We believe that revealing the molecular mechanism behind this
304 process would shed light on broad areas of biology, such as the diversity of muscle
305 patterning among species or regenerative medicine.
306

307

308 **Acknowledgements**

309 We thank Drs. Scherer, Kist and Ohteki (TMDU) for providing the *Sox9 flox* and
 310 *Rosa26-LSL-DTA* mice. This Research is supported by AMED-CREST from AMED
 311 (JP20gm0810008), MEXT KAKENHI (19K06697), the Nakatomi Foundation, the
 312 Nakajima Foundation and the Takeda Science Foundation for M.I.

319

320 **Declaration of Interests**

321 The authors declare no conflicts of interest in association with the present study.

322

323 **Methods**

324 **Mice**

325 A *ScxCre-L* transgenic (Tg) mouse strain has been described previously (Sugimoto,
326 Takimoto, Hiraki, & Shukunami, 2013b). A *Rosa26-LSL-DTA* mouse strain was kindly
327 provide by Dr. Ohteki. The mouse was originally purchased from Jackson Laboratory
328 (*B6.129P2-Gt(ROSA)26Sortm1(DTA)Lky/J*, strain#009669) by Dr. Ohteki and
329 transferred under the permission of Jackson Lab. A *Mohawk-Venus* knock-in mouse was
330 generated and described in our previous study (Ito et al., 2010). *Myf5Cre*
331 (*B6.129S4-Myf5^{tm3(cre)Sor}/J*, strain#007893) (Tallquist, Weismann, Hellström, & Soriano,
332 2000) and *Meox2Cre* mice (*B6.129S4-Meox2^{tm1(cre)Sor}/J*, strain#003755) (Tallquist &
333 Soriano, 2000) were purchased from Jackson Laboratory. A Sox9-flox mouse strain was
334 kindly provided by Dr. Scherer and Dr. Kist (Kist, Schrewe, Balling, & Scherer, 2002).
335 ICR mice were purchased from Sankyo lab-service (Tokyo, Japan). All animal
336 experiments were approved by the animal experiment committees of Meiji University
337 (approval No. IACUC17-0007) and the National Research Institute for Child Health and
338 Development (approval No. A2004-003).

339

340 **Histological analyses**

341 For paraffin sections, embryos were fixed with 4% paraformaldehyde (PFA) for 4°C

342 overnight, dehydrated with methanol, cleared with xylene and embedded in paraffin

343 For cryosection, embryos were fixed with 4% PFA for 4°C overnight, washed with PBS

344 and embedded with OCT compound (Sakura Finetek, Osaka, Japan). The embryos were

345 sectioned at 7 µm for hematoxylin and eosin (H&E) staining, and TUNEL and

346 immunofluorescence analyses. The TUNEL analysis was performed using an In situ

347 Death Detection Kit (Roche, Basel, Switzerland) according to the manufacturer's

348 instruction. The names of muscles and tendons appeared in sections were judged

349 according to Watson et al. (Watson, Riordan, Pryce, & Schweitzer, 2009).

350

351 **Immunohistochemistry**

352 The embryos were fixed with 4% PFA at 4°C overnight, dehydrated with methanol and

353 rehydrated with PBS supplemented with 0.1% triton-X100 (PBSTx). The embryos were

354 digested with 10 µg/ml Protease K at 37°C for 60 min, re-fixed with 4% PFA, blocked

355 with 2% BSA/PBSTx and incubated with α -MHC antibody (Sigma-Aldrich, St. Louis,
356 USA, My-32, 1:1000 in 2% BSA/PBSTx) at 4°C overnight. Then the embryos were
357 washed 10 times with PBSTx, incubated with α -mouse IgG-AP conjugated (1:2000 in
358 2% BSA/PBSTx) (ab5880 Abcam, Cambridge, UK) at 4°C overnight, washed 10 times
359 with PBSTx and the signal was developed in NBT/BCIP solution (Roche).

360

361 **Immunofluorescence**

362 Paraffin or cryosections were prepared as described in the histology section, boiled in
363 citric acid (pH 2.0) for antigen retrieval and stained with an α -MHC antibody (Sigma
364 My-32, 1:1000) or α -GFP antibody (Abcam ab13970, 1:1000). α -mouse IgG-Cy3
365 (Jackson ImmunoResearch, West Grove, USA, 1:1000) or α -chicken IgG-Alexa488
366 (Thermo Fisher, Waltham, USA, 1:1000) were used as secondary antibodies.

367

368 **Whole mount *in situ* hybridization**

369 Whole mount *in situ* hybridization (WISH) was performed according to the methods of
370 Yokoyama et al. (Yokoyama et al., 2009). Briefly, the embryos were fixed with 4% PFA

371 at 4°C overnight, dehydrated with methanol and rehydrated with PBS supplemented
372 with 0.1% tween20 (PBST). The embryos were digested with 10 µg/ml Protease K at
373 37°C for 20-60 min (depending on the stage), re-fixed with 4% PFA, and hybridized
374 with an anti-sense probe labeled with digoxigenin (DIG) or fluorescein in hybridization
375 buffer at 65°C overnight. The embryos were washed with wash buffer at 65°C, blocked
376 with 10% FBS/PBST for 2 hours, and incubated with α -DIG or α -fluorescein antibody
377 conjugated with alkaline phosphatase (Roche, 1:2000 in 10% FBS/PBST) at 4°C
378 overnight. Then the embryos were washed 10 times with PBST and the signal was
379 developed in NBT/BCIP solution (Roche). For double *in situ* hybridization,
380 DIG-labeled *tnmd* probe and fluorescein-labeled *myh3* probe were simultaneously
381 hybridized. *Tnmd* was stained with α -DIG-AP antibody and NBT/BCIP substrate,
382 post-fixed with 4% PFA, dehydrated with methanol, rehydrated with PBST and *myh3*
383 was stained with α -fluorescein-AP antibody and INT (Roche)/BCIP (Roche) substrates.
384 The sequences of the primers used for the amplification of probe are as follows:
385 *myogenin* fw: 5'- ACCTGATGGAGCTGTATGAGACATC -3', *myogenin* rev: 5'-
386 CATTAGGTGACACTATAGCAGATGTGCACACTTGTCCAGG -3', *myh3* fw: 5'-

387 CGTTTTGGACATTGCGGGTT -3', *myh3* rev: 5'- ATGGACTCCCTCCTCTGCAT

388 -3'.

389

390 **Skeletal preparation**

391 The embryos were removed with their skin and internal organs, fixed with 100%

392 ethanol, and serially stained with 0.03% alcian blue (Sigma-Aldrich) solution and

393 0.01% alizarin red (Sigma-Aldrich) solution. When embryos were used after

394 whole-mount IHC, the embryos were post-fixed with 4% PFA, dehydrated with ethanol

395 and stained as described above.

607 **The muscle shape and position were altered in the *Scx-DTA* mouse.**

608 (A-H) Whole-mount immunohistochemistry of myosin heavy chain (MHC) in forelimbs
 609 of P0 pups. Del.: Deltoid muscle. The blue arrowhead in C indicates the normal
 610 insertion site of the deltoid muscle (deltoid tuberosity). The red arrowhead in G
 611 indicates an altered insertion site of the deltoid (shoulder joint). The arrows in D and H
 612 indicate the extensor pollicis muscles. The blue arrowheads in D indicate separated
 613 ECU and EDQ muscles. The red arrowhead in H indicates fused ECU/EDQ muscle.
 614 (I-O) Immunofluorescence of MHC and MxVn (using α -EGFP) in the forelimbs of an
 615 E18.5 embryo. The blue arrowhead in J' indicates FDS tendons. The red arrowhead in
 616 M' indicates distally dislocated FDS muscle. The blue arrowhead in K indicates FDS
 617 muscles that are missing in the *Scx-DTA* mouse (red arrowhead in N). The blue arrow in
 618 K indicates normal extensor carpi muscles in a control embryo. The red arrow in N
 619 indicates rearranged extensor carpi muscles in an *Scx-DTA* embryo. The photograph in
 620 O shows the position of sections I-N. Scalebar: 100 μ m. (P-S) Whole-mount
 621 immunohistochemistry of MHC in E17.5 embryos. The blue arrowhead in P' indicates

622 the normal insertion site of the pectoralis major muscle (deltoid tuberosity). The red
623 arrowhead in R' indicates a dislocated insertion site of the pectoralis major muscle
624 (elbow joint). The blue arrowhead in Q' indicates the normal insertion site of the gluteus
625 maximus muscle (gluteus tuberosity). The red arrowhead in S' indicates a dislocated
626 insertion site of the gluteus major muscle (knee joint). (T-W) Whole-mount in situ
627 hybridization of *myh3* in the rectus abdominus (T, V, Rec. Abdomin.) and diaphragm (U,
628 W). The blue arrowheads in T and U indicate the normal organization of abdominal
629 muscles. The red arrowheads in V and W indicate a disorganized pattern of abdominal
630 muscles. The arrows in U and W indicate the width of the central tendons. For all of the
631 experiments, at least three pups/embryos were examined (n>3) and consistent results
632 were obtained. The figures show representative results.

633

634

635 Figure 3

636 **Loss of the tendon cells affects the patterning of myofibers.**

637 (A-F) A whole-mount in situ hybridization (WISH) analysis visualized the myoblast
638 localization. The blue arrowheads in A and D indicate the normal migration of
639 *Pax3*-positive myoblasts into the E11.5 limb. The blue arrowheads in B and E indicate
640 the normal segregation of *Myog*-positive myoblasts in the E12.5 limb. The blue
641 arrowheads in C and F indicate normal positioning of *Myog*-positive myoblasts in the
642 E13.5 limb. (G-L) A WISH analysis visualizes myofiber patterning. The blue
643 arrowheads in G and J indicate the normal location of *Myh3*-positive myofibers in the
644 E12.5 limb. The blue arrowheads in H and I indicate the normal boundaries of the
645 *Myh3*-positive FDC muscle bundle in E13.5 and E14.5 limbs. The red arrowheads in K
646 and L indicate obscure or fused boundaries of the *Myh3*-positive FDC muscle bundle in
647 E13.5 and E14.5 limbs. (M-P) Whole-mount immunohistochemistry visualized myosin
648 heavy chain (MHC)-positive myofibers in E14.5 embryos. The blue arrowheads in M
649 and N indicate the normal insertion site of the deltoid muscle (deltoid tuberosity). The
650 red arrowheads in O and P indicate a dislocated insertion site of the deltoid muscle

651 (shoulder joint). At least three embryos were examined in all the experiments ($n>3$) and

652 consistent results were obtained. The figures show representative results

653

654 Figure 4

655 **The attachment site of muscle was repositioned after myofiber differentiation.**

656 (A, D) Whole-mount immunohistochemistry visualized myosin heavy chain
 657 (MHC)-positive myofibers in the hind limb of E14.5 embryos. Dotted lines indicate the
 658 position of the section shown in B, C, E, and F. Arrowheads indicate the position of the
 659 gluteus tuberosities. (B, C, E, F) The immunofluorescence analysis of the E14.5
 660 hindlimb. Arrowheads indicate the position of the gluteus tuberosities. Scalebar: 100 μ m.
 661 (G, J) Whole-mount immunohistochemistry visualized myosin heavy chain
 662 (MHC)-positive myofibers in the hind limb of E17.5 embryos. Dotted lines indicate the
 663 position of the section shown in H, I, K, and L. The blue arrowhead in G indicates the
 664 normal insertion site of the gluteus maximus muscle (gluteus tuberosity). The red
 665 arrowhead in J indicates the dislocated insertion site of the gluteus maximus muscle
 666 (knee joint). (H, I, K, L) The immunofluorescence analysis of the E17.5 hindlimb.
 667 Arrowheads indicate the position of gluteus tuberosities. Scalebar: 100 μ m. In all of the
 668 experiments, at least three embryos were examined (n>3) and consistent results were
 669 obtained. The figures show representative results

670

671 Figure S1

672 **Tendon/ligament-specific cell death was observed in the *Scx-DTA* mouse.**

673 (A-D) A TUNEL analysis of the E15.5 forelimb. (E-H) A TUNEL analysis of the E12.5
674 forelimb and shoulder. (I-P) H&E staining and a TUNEL analysis of the E12.5 vertebrae
675 and tail.

676

677 Figure S2

678 **The deltoid tuberosity is missing in the *Scx-DTA* mouse.**

679 (A, B) Alcian-blue and alizarin-red staining of P0 pups. The blue arrowhead indicates
680 the normal deltoid tuberosity in a control limb (A), which is missing in the *Scx-DTA*
681 forelimb (B, red arrowhead)

682

683 Figure S3

684 **Muscle patterning was not affected in the hindlimb of the *Scx-DTA* mouse.**

685 (A, C) Whole-mount immunohistochemistry visualized MHC-positive myofibers in the
686 P0 hindlimb. (B, D) An immunofluorescence analysis of MHC in an E15.5 hindlimb

687 section. Scale bar: 100 μ m

688

689 Figure S4

690 **The MCT gene expression was not changed in the *Scx-DTA* mouse.**

691 Quantitative RT-PCR showed a significant reduction in the expression of tendon genes

692 in the E14.5 *Scx-DTA* forelimb; however, the expression of MCT genes was not

693 changed. Student's t-test was performed. * $p < 0.05$, ** $p < 0.01$, n.s.: no significant

694 difference.

695

696 Figure S5

697 **The high expression of *Myh3* marks the muscle-tendon junction.**

698 A whole-mount in situ hybridization (WISH) analysis visualized the *Myh3* and *Tnmd*

699 expression in the E14.5 hindlimbs. In A and D, *Myh3* was stained with INT/BCIP

700 (orange) and *Tnmd* was stained with NBT/BCIP (blue). Arrowheads indicate the

701 putative junction between the EDL muscle and the EDL tendon.

702

703 Figure S6

704 **Skeletal malformation did not affect muscle patterning.**

705 (A, C) Whole-mount immunohistochemistry visualized MHC-positive myofibers in
706 E16.5 pectoral muscles. The blue arrowheads indicate the normal insertion site of the
707 pectoralis major muscles (deltoid tuberosity) in control and *Sox9* heterozygous embryos.

708 (B, D) Alcian-blue and alizarin-red staining showing the skeletal elements of embryos
709 shown in A and C. The blue arrowhead indicates the normal deltoid tuberosity in a
710 control limb (B), which is missing in the *Sox9* heterozygous forelimb (D, red

711 arrowhead). (E, G) Whole-mount immunohistochemistry visualized MHC-positive
712 myofibers in the E16.5 pectoral muscles. The blue arrowheads indicate the normal
713 insertion site of the pectoralis major muscles (deltoid tuberosity) in control and

714 *Myf5*^{Cre/Cre} embryos. (F, H) Alcian-blue and alizarin-red staining showing the skeletal
715 elements of embryos shown in E and G. The blue arrowhead indicates a normal rib cage
716 in a control embryo (E), which is diminished in *Myf5*^{Cre/Cre} embryo (H, red arrowhead).

717 (I, J) Whole-mount immunohistochemistry visualized MHC-positive myofibers in the

718 E16.5 pectoral muscles. The blue arrowheads indicate the normal insertion site of the
719 pectoralis major muscles (deltoid tuberosity) in control and *Myf5-DTA* embryos.

720

721 Figure S7

722 **Dislocation of the insertion site toward the joint region where tendon cells are**
723 **abundant.**

724 (A) The immunofluorescence analysis of MxVen (using α -EGFP) in the E17.5 femur
725 of control (upper panel) and *Scx-DTA* (lower panel) embryos. The blue arrowheads
726 indicate the proximal and distal tendons for the gluteus major muscle in the control
727 embryo, which are missing in the *Scx-DTA* embryo (red arrowhead). Yellow arrowheads
728 indicate a comparable amount of tendon tissue in the knee joint of control and *Scx-DTA*
729 embryos. (B) Whole-mount in situ hybridization of *myh3* in the E14.5 forelimb of
730 control and *Scx-DTA* embryos. The blue arrowheads indicate the normal attachment
731 sites of limb muscles. The red arrowhead indicates the accumulation of attachment sites
732 to the shoulder joint.
