Abstract

Coronaviruses (CoV) are a family of RNA viruses that typically cause respiratory, enteric and hepatic diseases in animals and humans. Here, we used porcine epidemic diarrhea virus (PEDV) as a model of coronaviruses (CoVs) to illustrate the reciprocal regulation between CoVs infection and pyroptosis. For the first time, we clarified the molecular mechanism of porcine Gasdermin D (pGSDMD)-mediated pyroptosis and demonstrated that amino acids T239 and F240 within pGSDMD-p30 are critical for pyroptosis. Furthermore, 3C-like protease Nsp5 from SARS-CoV-2, MERS-CoV, PDCoV and PEDV can cleave human/porcine GSDMD at the Q193-G194 junction upstream of the caspase-1 cleavage site to produce two fragments which fail to trigger pyroptosis or inhibit viral replication. Thus, we provide clear evidence that coronaviruses may utilize viral Nsp5-GSDMD pathway to help their host cells escaping from pyroptosis, protecting the replication of the virus during the initial period, which suggest an important strategy for coronaviruses infection and sustain.

Keywords: Coronaviruses; GSDMD; Pyroptosis; Nsp5

Introduction

Coronaviruses (CoVs) are enveloped positive single-strand RNA viruses which belong to the family of *Coronaviridae*. These viruses can cause enteric, respiratory or hepatic diseases in both human and other mammals¹. According to serological and genotypic characterizations, CoVs are divided into four genera, including *Alphacoronavirus* (α -CoV), *Betacoronavirus* (β -CoV), *Gammacoronavirus* (γ -CoV) and *Deltacoronavirus* (δ -CoV)^{2,3}. As a member of the *Alphacoronavirus* genus, porcine epidemic diarrhea virus (PEDV) was first identified in Europe in 1971 which characterized by severe diarrhea, dehydration, vomiting and high mortality in suckling piglets⁴. A highly virulent PEDV reemerged in China in 2010 and spread rapidly in the USA in 2013, causing enormous economic losses to the global pig farming industry⁵⁻⁷. The viral genome of PEDV is approximately 28 kb and encodes an accessory protein, two polyproteins and 4 structural proteins. Most of synthesized polyproteins are cleaved by nonstructural protein 5 (Nsp5), a 3C-like protease encoded by ORF1a, and the protease activity of Nsp5 is essential for PEDV's replication. Nsp5 from different CoVs share highly conserved amino acid sequence which makes Nsp5 as an ideal broad-spectrum antiviral target^{8,9}. It has been reported that 3C-like protease of

different viruses, including foot-and-mouth disease (FMDV), hepatitis A virus (HAV) and enterovirus 71 (EV71), can antagonize innate immune signaling pathways by disrupting one or more components of the IFN-inducing pathways¹⁰⁻¹⁴. For coronaviruses, PEDV Nsp5 antagonizes type I IFN signaling by cleaving the nuclear transcription factor kappa B essential modulator (NEMO) at Q231¹⁵. Porcine deltacoronavirus (PDCoV) Nsp5 cleaves the porcine mRNA-decapping enzyme 1a (pDCP1A) at Q343 to facilitate its replication¹⁶. A recently published study demonstrates that SARS-CoV-2 Nsp5 can cleave TAB1 and NLRP12 at two distinct cleavage sites¹⁷. Although many studies have demonstrated the immune evasion strategies of coronaviruses, the molecular mechanism between coronaviruses replication and the innate immune response remains poorly understood.

Pyroptosis is a form of programmed cell death which characterized by cell swelling, pore formation in the plasma, lysis and releases of cytoplasmic contents^{18,19}. This type of inflammatory cell death functions as an innate immune effector to antagonize pathogenic microorganisms. Recent studies identified Gasdermin D (GSDMD) as an executioner of pyroptosis, which is cleaved and activated by caspase-1 and caspase-4/5/11¹⁸⁻²⁰. Upon caspase-1/4/5/11 cleavage, the N-terminus of GSDMD (GSDMD-p30) can bind to lipids and phosphatidylethanolamine to form pores at 10-20 nm in size and drive to pyroptosis²¹⁻²³. Under the condition of pathogen infection, the pyroptosis helps the host eliminating infected cells and thereby restricts proliferation of intracellular pathogens²⁴⁻²⁶. On the other hand, the 3C-like protease of EV71 virus can facilitate its replication by inhibiting pyroptosis through further cleaving the active GSDMD-p30²⁷. However, the relationship between coronaviruses infection and GSDMD-mediated pyroptosis has not been fully illustrated.

In this study, we used PEDV as a model of CoVs to investigate the relationship between CoVs infection and pyroptosis. We found that the pGSDMD-mediated pyroptosis protected host cells against PEDV infection. However, during the early stage of infection, Nsp5 of PEDV directly cleaved pGSDMD at the Q193-G194 junction and produced two inactive fragments, which do not inhibit PEDV replication. Furthermore, we found Nsp5 from other coronaviruses, such as PDCoV, SARS-CoV-2 and MERS-CoV, had activity to cleave both hGSDMD and pGSDMD to inhibit GSDMD-mediated pyroptosis. Therefore, these results demonstrated a previously unknown mechanism of coronaviruses to escape from the pyroptosis of innate immune responses.

Results

PEDV infection induces the degradation of pGSDMD. Since GSDMD was reported as a key effector for pyroptosis, many studies had been performed on human and murine GSDMD, but studies focusing on pGSDMD and its function against pathogenic infection were rare. To investigate the role of pGSDMD on pathogenic infection, the amino acid sequence of pGSDMD was predicted and aligned with other GSDMD homologs from human and mouse (Extended Data Fig. 1), and polyclonal antibody against pGSDMD was prepared as previously described (Extended Data Fig. 2)^{28,29}.

To determine whether PEDV infection targets pGSDMD, IPEC-J2 cells were infected with PEDV at indicated time points. Cell death was evaluated by LDH release. The results showed that pyroptosis was inhibited at early timepoints post infection (Fig. 1A). Furthermore, PEDV infection induced degradation of pGSDMD in IPEC-J2 cells (Fig. 1B). Similar results were observed in Vero cells transfected with plasmid encoding pGSDMD and infected with PEDV (Fig. 1C and D). In addition, the degradation of pGSDMD induced by PEDV infection increased in an MOI-dependent manner in IPEC-J2 and Vero cells (Fig. 1E and F). These results indicate that pyroptosis and pGSDMD expression are both inhibited by PEDV infection in IPEC-J2 cells and Vero cells.

Caspase-1 cleaves pGSDMD at residue D279-G280 and induces pyroptosis. We next investigate whether pGSDMD could induce pyroptosis. Therefore, porcine caspase-1 (pCaspase-1) and pGSDMD gene were amplified and cloned into vectors to construct recombinant plasmids and then the plasmids were co-transfected into HEK293T cells. As shown in Fig. 2A, co-transfected with plasmids encoding pCaspase-1 and pGSDMD significantly increased the LDH release in HEK293T cells (Fig. 2A). To further confirm the results, the cells were collected and stained with PI, and then analyzed with Fluorescence microscopy and Flow cytometry (Extended Data Fig. 3A and B). Both results showed that co-transfection with plasmids encoding pCaspase-1 and pGSDMD led to increased cell death. These results indicate that co-expression of pGSDMD and pCaspase-1 could induce pyroptosis in HEK293T cells.

The cells were also collected to detect pCaspase-1 mediated cleavage of pGSDMD by Western

111 blotting. As shown in Fig. 2B, cell lysates co-transfected with HA-caspase-1 and
112 p3×Flag-N-GSDMD-FL had a faster-migrating protein band (about 35 kDa) and cell lysates
113 co-transfected with HA-caspase-1 and p3×Flag-C-GSDMD-FL had a smaller protein band (about
114 25 kDa). These results show that pCaspase-1 could cleave pGSDMD to generate an N-terminal
115 (about 30 kDa) and a C-terminal (about 20 kDa).

116 Based on the sizes of the cleaved protein bands and the cleavage site preference of caspase-1,
117 the D254-G255 and D279-G280 pairs were tested as the potential cleaved sites for pCaspase-1.
118 Hence, we constructed two mutants in which D was replaced with A. As shown in Fig. 2C and D,
119 wild-type pGSDMD, the D254A mutant and the D279A mutant were co-transfected with
120 pCaspase-1, followed by LDH release assays and PI staining assays. Both results showed that
121 mutation of D279 resulted in significantly decreased pyroptosis, while mutant of D254 showed no
122 significant change, which suggested pCaspase-1 cleaved pGSDMD at residue D279-G280. The
123 Western blotting analysis of the cell lysates was consistent with this result (Fig. 2E), in which the
124 wild-type pGSDMD and the D254A mutant were cleaved by pCaspase-1 and the D279A mutant
125 was resistant to the cleavage. The results indicate that pCaspase-1 cleaves pGSDMD at residue
126 D279-G280 and generated an N-terminal (GSDMD₁₋₂₇₉) which could induce pyroptosis (Fig. 2F).

127 To further validate the results, plasmids encoding pGSDMD₁₋₂₇₉ was constructed and
128 transfected into HEK293T cells. The LDH release assays showed that pGSDMD₁₋₂₇₉ individually
129 induced pyroptosis (Fig. 2G). Thus, the above results suggest that pGSDMD is cleaved by
130 pCaspase-1 at residue D279-G280 and then generate an N-terminal (p30) which could induce
131 pyroptosis and a C-terminal (p20) (Fig. 2H).

132

133 **L295/Y378/A382 are the key sites for pGSDMD autoinhibition.** It has been reported that the
134 residues C38/C39 and C191/C192 (human/murine) are essential for oligomerization of
135 GSDMD-N terminal^{21,30}. Hence, we next examined whether these key sites also existed on
136 pGSDMD. Based on the multiple-sequence alignment of pGSDMD, hGSDMD and murine
137 GSDMD (mGSDMD) (Extended Data Fig. 1), residues C38 and S191 were tested as the potential
138 key sites for pGSDMD to oligomerize and they were replaced with A to construct point mutants.
139 HEK293T cells were transfected with these point mutants, LDH release results showed that C38A
140 and S191A did not show inhibitory effects on pyroptosis (Fig 3A). However, we further evaluated

the oligomerization of pGSDMD-p30 following treatment of NSC and NSA (two specific inhibitors for oligomerization of hGSDMD-p30)^{30,31}. As shown in Fig. 3B, the results showed that both NSC and NSA inhibited the pyroptosis induced by porcine/human GSDMD-p30 (Fig. 3B), suggesting that there are residues which impact the oligomerization of pGSDMD-p30 and still required further exploration in the future.

Earlier reports have demonstrated that full length of hGSDMD and mGSDMD have an autoinhibitory structure, in which GSDMD-C terminal inhibits the activity of GSDMD-N terminal to induce pyroptosis^{23,30}. Based on the multiple-sequence alignment, L295, Y378 and A382 of pGSDMD formed a pocket which associated with GSDMD-N terminal according to the homology modeling results (Fig. 3C). Thus, the three residues were tested as the potential sites in pGSDMD. These residues were separately mutated into D (GSDMD-FL-L295D/GSDMD-FL-Y378D/GSDMD-FL-A382D), L295 and Y373 were simultaneously mutated into D (GSDMD-FL-2D), and three residues were simultaneously mutated into D (GSDMD-FL-3D). The mutants were transfected into HEK293T cells, and results showed that all of the mutants had the activity to induce pyroptosis (Fig. 3D). However, there were no statistic differences between 2D and 3D (Fig. 3E). The aforementioned results suggest that L295, Y378 and A382 are the critical sites for autoinhibitory structure of full length of pGSDMD.

PEDV Nsp5 associates with and cleaves pGSDMD. To investigate the relationship between PEDV infection and pyroptosis, Vero cells were transfected with plasmids encoding pGSDMD full-length (pGSDMD-FL) and GSDMD N-terminal (pGSDMD-p30) and then infected with PEDV. The LDH release assays results showed that PEDV infection had an inhibition effect on pyroptosis induced by pGSDMD-p30 (Fig. 4A). Meanwhile, the replication of PEDV was also inhibited significantly by pyroptosis induced by pGSDMD-p30 (Fig. 4B). These results suggest that there might be reciprocal regulation between PEDV and the pGSDMD-p30-mediated pyroptosis.

Nonstructural protein 5 (Nsp5), the 3C-like protease, which mediates the cleavage of viral polyproteins, has reported be able to cleave a number of host proteins, such as DCP1A and NEMO, to suppress antiviral host responses^{10,11,15,16}. Therefore, we speculated that PEDV Nsp5 can cleave

171 pGSDMD to suppress pyroptosis. As shown in Fig. 4C, HEK293T cells were transfected with
 172 PEDV Nsp5 or pGSDMD-p30, or co-transfected with these two recombinant plasmids. The
 173 supernatants were collected at different time points and tested for LDH release. The results
 174 showed that the expression of PEDV Nsp5 inhibited pyroptosis induced by pGSDMD-p30 (Fig.
 175 4C). For further validation, HEK293T cells were transfected with plasmids as indicated in Fig. 4D,
 176 and the Western blotting results showed that there was a faster-migrating protein band (about 25
 177 kDa) in samples co-transfected with PEDV Nsp5 and p3×Flag-N-GSDMD-FL (Fig. 4D, lane 6),
 178 and there were two cleavage protein bands, of 35 kDa (p30) and 25 kDa respectively, in samples
 179 co-transfected with HA-caspase-1, PEDV Nsp5 and p3×Flag-N-GSDMD-FL (Fig. 4D, lane 7).
 180 These results implied that pGSDMD was a target cleaved by PEDV Nsp5. To further confirm the
 181 pGSDMD cleavage mediated by PEDV Nsp5, p3×Flag-N-GSDMD-FL was co-transfected with an
 182 increasing dose of PEDV Nsp5 into HEK293T cells. Western blotting results showed that
 183 pGSDMD cleavage progressively increased in a PEDV Nsp5-dose-dependent manner (Fig. 4E).
 184 We next investigated the colocalization of pGSDMD and PEDV Nsp5 with confocal microscopy.
 185 As shown in Fig. 4F, HEK293T cells were transfected with plasmids as shown and the protein
 186 localization were examined after 24 h. An indirect immunofluorescence assay showed that
 187 pGSDMD and Nsp5 colocalized in the cytoplasm (Fig. 4F). The CoIP experiments also
 188 demonstrated that PEDV Nsp5 interacted with and cleaved pGSDMD (Fig. 4G).

189 To further investigate whether PEDV Nsp5 cleaves pGSDMD by means of its protease activity,
 190 two Nsp5 mutants, H41A and C144A, which disrupted the protease activity of Nsp5^{8,32-34}, were
 191 constructed and co-transfected with p3×Flag-N-GSDMD-FL into HEK293T cells. As shown in
 192 Fig. 4G, wild-type Nsp5 cleaved pGSDMD successfully, while the two mutants failed to cleave
 193 pGSDMD (Fig. 4H). Nevertheless, CoIP experiments showed that the loss of protease activity of
 194 Nsp5 did not impact its interaction with pGSDMD (Fig. 4I). Hence, the protease activity of PEDV
 195 Nsp5 is essential for pGSDMD cleavage but not interaction.

196

197 **PEDV Nsp5 cleaves pGSDMD at residue Q193-G194.** We next examined the sequence of
 198 pGSDMD for potential PEDV Nsp5 cleavage site. Logo analysis of the cleavage site predicted
 199 from the polypeptide cleavage of PEDV Nsp5 was shown in Fig. 5A. Based on the substrate
 200 preference of Nsp5 and the sizes of the cleaved bands, the Q193-G194, Q195-G196 and

201 Q197-G198 pairs were tested as the potential cleaved sites^{35,36}. Therefore, these three Q residues
 202 were replaced with A and these three mutants pGSDMD-Q193A, pGSDMD-Q195A,
 203 pGSDMD-Q197A were co-transfected with vector or PEDV Nsp5. As shown in Fig. 5B, Western
 204 blotting results showed that pGSDMD-Q193A was resistant to PEDV Nsp5-mediated cleavage,
 205 while pGSDMD-Q195A and pGSDMD-Q197A were not (Fig. 5B), suggesting that PEDV Nsp5
 206 cleaves pGSDMD at residue Q193-G194 junction (Fig. 5C).

207 PEDV Nsp5 cleaves pGSDMD to generate pGSDMD₁₋₁₉₃ and pGSDMD₁₉₄₋₄₈₈, and pCaspase-1
 208 cleaves pGSDMD at residue D279. Thus, we next investigated whether these cleaved fragments of
 209 pGSDMD₁₋₁₉₃, pGSDMD₁₉₄₋₂₇₉ and pGSDMD₁₉₄₋₄₈₈ can induce pyroptosis. As shown in Fig. 5D,
 210 these three truncated mutants were separately transfected into HEK293T cells and results showed
 211 that none of them induced pyroptosis (Fig. 5D). Meanwhile, since the protein band of
 212 pGSDMD₁₉₄₋₂₇₉ was too small to be visualized, we subsequently cloned them into EGFP-tagged
 213 vectors and then transfected them into HEK293T cells. The results further confirmed that these
 214 three truncated mutants cannot induce pyroptosis (Extended Data Fig. 4). Next, we further
 215 examined whether pCaspase-1 could associate with and cleave these three truncated mutants. As
 216 shown in Fig. 5E and F, HEK293T cells were co-transfected with plasmids as indicated, and the
 217 results of CoIP assay and Western blotting assays showed that pCaspase-1 could associate with
 218 and cleave full-length of pGSDMD, but had no interaction with pGSDMD₁₋₁₉₃, pGSDMD₁₉₄₋₂₇₉
 219 and pGSDMD₁₉₄₋₄₈₈.

220 As described in the preceding text, pyroptosis of cells induced by pGSDMD-p30 had an
 221 inhibition effect on PEDV replication. Therefore, we next investigated whether PEDV
 222 Nsp5-mediated cleavage of pGSDMD impacts its antiviral activity. Vero cells were transfected
 223 with plasmids encoding vector, pGSDMD-FL, pGSDMD-p30, pGSDMD₁₋₁₉₃, pGSDMD₁₉₄₋₂₇₉ and
 224 pGSDMD₁₉₄₋₄₈₈. At 24 h after transfection, cells were infected with PEDV at an MOI of 0.5 for
 225 another 24 h, and then total RNA was extracted and the viral RNA level of PEDV were evaluated
 226 by quantitative real-time PCR. As shown in Fig. 5G, there was no statistical differences among
 227 vector, pGSDMD-FL, pGSDMD₁₋₁₉₃, pGSDMD₁₉₄₋₂₇₉ and pGSDMD₁₉₄₋₄₈₈, indicating that the
 228 antiviral activity of fragments cleaved by Nsp5 were nearly abolished (Fig. 5G). In summary, the
 229 above results demonstrate that the antiviral activity of pyroptosis induced by pGSDMD-p30 are
 230 impaired by PEDV Nsp5-mediated cleavage, which emphasizes the importance of pGSDMD

231 cleavage on PEDV replication.

232

233 **Amino acids T239 and F240 are two key sites for pGSDMD-p30 to induce pyroptosis.** It has
 234 been shown that pGSDMD₁₋₂₇₉ (pGSDMD-p30) can induce pyroptosis, while pGSDMD₁₋₁₉₃
 235 cannot. Based on this, we conjectured that the active motif of pGSDMD to induce pyroptosis
 236 located at the amino acids between 193 and 279. Thus, we constructed a series of pGSDMD
 237 truncated mutants which encoding pGSDMD₁₋₂₅₄, pGSDMD₁₋₂₄₄, pGSDMD₁₋₂₃₄, pGSDMD₁₋₂₂₄,
 238 and pGSDMD₁₋₂₁₄, and transfected them into HEK293T cells. As shown in Figure 6A and B,
 239 pGSDMD₁₋₂₇₉ (pGSDMD-p30), pGSDMD₁₋₂₅₄ and pGSDMD₁₋₂₄₄ can induce pyroptosis, while
 240 pGSDMD₁₋₂₃₄, pGSDMD₁₋₂₂₄, pGSDMD₁₋₂₁₄ cannot (Fig. 6A and B), indicating that the key sites
 241 located between amino acids 234 and 244. Hence, the amino acids between 234 and 244 were
 242 replaced by D and these point mutants were transfected into HEK293T cells as shown in Fig. 6C.
 243 The results showed that all of the point mutants, except T239D and F240D (Fig. 6C), can induce
 244 pyroptosis, suggesting that T239 and F240 are the essential sites for pGSDMD-p30 to induce
 245 pyroptosis. The results were further proved by PI staining assay (Extended Data Fig. 5). Notably,
 246 the point mutant R238D can inhibit the release of LDH but cannot inhibit the intake of PI,
 247 suggesting that the mutation of R238 led to smaller pores on cell membrane than wild type
 248 pGSDMD-p30.

249 To further investigate the effects of T239D and F240D on viral replication, the two mutants
 250 were transfected into Vero cells along with vector, pGSDMD-FL and pGSDMD-p30, and 24 h
 251 after transfection, cells were infected with PEDV at an MOI of 0.5 and then the replication of
 252 virus were tested by quantitative real-time PCR. As presented in Fig. 6D, in contrast to
 253 pGSDMD-p30, neither T239D nor F240D could inhibit the replication of PEDV (Fig. 6D), further
 254 confirming that inhibition of pyroptosis induced by pGSDMD-p30 is essential for PEDV to
 255 replicate.

256

257 **GSDMD is a common substrate of different coronaviruses Nsp5.** Next, we tested whether
 258 Nsp5 encoded by other genera of CoVs can cleave GSDMD. Multiple-sequence alignment
 259 showed that Nsp5 of PDCoV, SARS-CoV-2 and MERS-CoV were highly similar to PEDV Nsp5
 260 (Extended Data Fig. 6), especially their catalytic domain (Fig. 7A). Thus, the Nsp5 of PDCoV,

261 SARS-CoV-2 and MERS-CoV were cloned into empty vector and co-transfected with pGSDMD,
262 and the Western blotting results showed that all these Nsp5 can cleave pGSDMD (Fig. 7B). To
263 further confirm the results, we respectively constructed point mutants of these Nsp5 which did not
264 show protease activity. As shown in Fig. 7C, PDCoV Nsp5 can cleave pGSDMD while its mutants
265 cannot (Fig. 7C). Likewise, the wild-type Nsp5 of SARS-CoV-2 cleaved both pGSDMD (Fig. 7D)
266 and hGSDMD (Fig. 7E), while its mutants did not. Similar results were observed for cleavage of
267 pGSDMD and hGSDMD by MERS-CoV Nsp5 (Fig. 7F and G). The results above suggest that
268 GSDMD is a common substrate of different genera of coronaviruses Nsp5. To further validate this
269 conclusion, we analyzed the peptides GAVSLQ(193)↓GQGQGH (pGSDMD, arrow represents
270 cleavage site) and Nsp5 of PEDV (Fig. 8A), SARS-CoV-2 (Fig. 8B), MERS-CoV (Fig. 8C) and
271 PDCoV (Fig. 8D), peptides GATCLQ(193)↓GEGQGH (hGSDMD, arrow represents cleavage site)
272 and Nsp5 of SARS-CoV-2 (Fig. 8E) and MERS-CoV (Fig. 8F) by homology modeling^{37,38}. As
273 shown in Fig. 8, the residues of both pGSDMD and hGSDMD comfortably fit in the Nsp5 pockets
274 of different CoVs, suggesting a strong interaction between them.

275

276 Discussion

277 Although considerable progress has been made in CoVs research, knowledge gaps still exist with
278 respect to the host innate immune responses against CoVs infection. Here, we used PEDV as a
279 model of CoVs to illustrate the relationship between CoVs infection and pyroptosis (Fig. 9). We
280 demonstrated that the pGSDMD plays a protective role against PEDV infection. At early time
281 points after PEDV infection, pGSDMD was cleaved by Nsp5 to produce two inactive fragments
282 which failed to trigger pyroptosis and inhibited PEDV replication. The pGSDMD-p30 could
283 inhibit PEDV replication, and the amino acids T239 and F240 determined its inhibitory effect.
284 Furthermore, Nsp5 of other genera can also cleave hGSDMD and pGSDMD to produce inactive
285 fragments. Thus, our results demonstrated that GSDMD may be an appealing target for the design
286 of anti-coronavirus therapies.

287 Recent studies have identified that human/murine GSDMD is a direct substrate of
288 caspase-1/4/5/11 and serves as the executioner for pyroptosis. However, the amino acids sequence
289 and molecular characterization of pGSDMD have not been illustrated. In order to investigate the

290 role of pGSDMD-mediated pyroptosis in PEDV infection, we first clarified the molecular
 291 characterization of pGSDMD. Porcine GSDMD has 488 aa and can be cleaved by porcine
 292 caspase-1 at D279 to produce GSDMD-NT (p30, 1-279 aa), which lead to pyroptosis.
 293 Site-directed mutagenesis studies revealed that C38/C39 and C191/C192 (human/murine)
 294 mutations impaired hGSDMD-p30/mGSDMD-p30 oligomerization, which is critical for
 295 hGSDMD-p30/mGSDMD-p30 during pore formation^{22,30}. However, our results indicated that
 296 mutation of porcine C38 or S191 (corresponding to human C38 and C191) had no effect on
 297 p30-induced pyroptosis. Interestingly, inhibitors of hGSDMD-p30 oligomerization could also
 298 abrogate pGSDMD-p30-induced pyroptosis. The results suggest that other critical site(s)
 299 determine(s) pGSDMD-p30 oligomerization. Furthermore, our results demonstrated that T239 and
 300 F240 within pGSDMD-p30 are critical for inducing pyroptosis.

301 Generally, the 3C-like protease of CoVs is critical for viral replication by cleaving polypeptide
 302 precursors to produce mature nonstructural proteins. However, the 3C-like protease has also
 303 acquired mechanisms to evade host innate immune responses. It is reported that CoVs Nsp5 can
 304 antagonize innate immune signaling pathways by disrupting one or more components of the
 305 IFN-inducing pathways¹⁰⁻¹². Our present study first demonstrated that CoVs Nsp5 can subvert
 306 innate immune responses by cleaving and inactivating GSDMD. Thus, GSDMD represents a
 307 novel target of CoVs Nsp5. PEDV Nsp5 not only interacted with and cleaved full length of
 308 pGSDMD, but also abrogated pGSDMD-p30-induced pyroptosis by cleaving the p30 fragment.
 309 Conversely, protease-dead mutants of the four CoVs Nsp5 were unable to cleave human/porcine
 310 GSDMD. Thus, these results suggest a reciprocal regulation between CoVs Nsp5 and pyroptosis.

311 It is noteworthy that CoVs Nsp5 cleaves human/porcine GSDMD at the Q193-G194 junction.
 312 Our results suggest that amino acids T239 and F240 within pGSDMD-p30 are critical for
 313 pyroptosis. These two sites within pGSDMD-p30 determine CoVs replication. Upon cleavage by
 314 CoVs Nsp5, the truncated N-terminal fragment without T239 and F240 sites failed to induce
 315 pyroptosis or inhibit viral replication. Interestingly, a newly published study demonstrated that
 316 Zika virus (ZIKV) protease directly cleaved the hGSDMD into N-terminal fragment (1-249),
 317 which contains T239 and F240. ZIKV NS2B3 protease cleaves hGSDMD at residue R249 to
 318 produce hGSDMD₁₋₂₄₉ fragment, which lead to pyroptosis in a caspase-independent manner³⁹.
 319 Consistent with this, a previous study demonstrated that NS5 protein of ZIKA could directly

320 interact with NLRP3 protein and facilitate NLRP3 inflammasome activation⁴⁰, which is an
321 upstream event for hGSDMD-p30-mediated pyroptosis. Therefore, viruses use different strategies
322 to evade host immune responses and facilitate its replication.

323 In summary, we used PEDV as a model of coronaviruses to illustrate the reciprocal regulation
324 between CoVs infection and pyroptosis. For the first time, we clarified the molecular mechanism
325 of pGSDMD-mediated pyroptosis and demonstrated that amino acids T239 and F240 within
326 pGSDMD-p30 are critical for pyroptosis. Furthermore, 3C-like protease Nsp5 from SARS-CoV-2,
327 MERS-CoV, PDCoV and PEDV can cleave human/porcine GSDMD at the Q193-G194 junction
328 upstream of the caspase-1 cleavage site to produce two fragments which fail to trigger pyroptosis
329 or inhibit viral replication. Thus, we provide clear evidence that the coronaviruses might utilize its
330 Nsp5 to escape the host pyroptotic cell death in favor of its replication during the initial period, an
331 important strategy for their sustaining infections. Further work is needed to investigate the role of
332 GSDMD in viral pathogenesis.

333

334 **Methods**

335 **Plasmids and antibodies.** The pGSDMD gene was amplified from cDNA of IPEC-J2 cells by
336 PCR and then cloned into p3×Flag-CMV-7.1 vector, p3×Flag-CMV-14 vector and pEGFP-C1
337 vector, respectively. Nsp5 of PEDV was amplified from cDNA of PEDV and cloned into
338 PRK5-MYC vector. The truncation mutants and point mutants were generated by PCR of the
339 corresponding plasmids. All of the plasmids were constructed by homologous recombination using
340 ClonExpress II One Step Cloning Kit (Vazyme, C112), and all of the point mutants were
341 constructed using Mut Express II Fast Mutagenesis Kit V2 (Vazyme, C214) and DpnI
342 endonuclease (NEB, R0176S). Primers used for plasmids construction were listed in
343 Supplementary table 1 and table 2. All plasmids were verified by sequencing.

344 Anti-Flag antibody (F1804), anti-MYC antibody (C3956) and anti-GSDMD antibody (G7422)
345 were purchased from Sigma. Anti-HA antibody (3724) was purchased from Cell Signaling
346 Technology. Anti-β-actin antibody (A01010) was purchased from Abbkine. Anti-GSDMD C1
347 antibody (sc-393581) was purchased from Santa Cruz. The anti-PEDV N monoclonal antibody
348 and the anti-GSDMD polyclonal antibody were prepared in our laboratory as previously

described^{28,29}. Necrosulfonamide (S8251) and Disulfiram (S1680) were purchased from Selleck.

350

Cells and virus. African green monkey kidney cells (Vero cells) and Human embryonic kidney 293T cells (HEK293T) were cultured in DMEM (Hyclone, SH30243.01) containing 10% fetal bovine serum (FBS) (Corille, C1015-05) and 5% Penicillin-Streptomycin Solution (Hyclone, SV30010). IPEC-J2 cells were maintained in DMEM/F12 (Hyclone, SH30023.01) supplemented with 10% FBS and 5% Penicillin-Streptomycin Solution. Cells were incubated at 37°C with 5% CO₂. When cells seeded in cell culture plates grown to approximately 60%, they were transfected with plasmids using VigoFect (Vigorous Biotechnology, T001) or Lipo8000 Transfection Reagent (Beyotime, C0533) according to the manufacturer's instructions.

The PEDV strain ZJ15XS0101 (GenBank accession KX550281) was isolated and stored in our laboratory⁴¹. Vero cells and IPEC-J2 cells grown to approximately 80%-90% in cell culture plates were infected with PEDV at different dose with 4 µg/mL trypsin.

362

Cytotoxicity assays. Cell death were measured using CytoTox 96 Non-Radioactive Cytotoxicity Assay kit (Promega, G1780) according to the lactate dehydrogenase (LDH) released into medium.

365

Western blotting. Cells were lysed with RIPA Lysis Buffer (Beyotime, P0013B) containing PMSF (Beyotime, ST506) for 10 min at 4°C and then denatured in 5 × SDS-PAGE loading buffer (Solarbio, P1040) for 10 min. After harvest, the cell lysate of equal amount was loaded on 8%-12% SDS-PAGE gels (Fdbio science) and electrophoresed, and then transferred to polyvinylidene difluoride membranes (BIO-RAD, 1620177). The membranes were blocked with QuickBlock Blocking Buffer for Western blotting (Beyotime, P0252) for 1 h and then incubated with primary antibodies diluted with QuickBlock Primary Antibody Dilution Buffer for Western blotting (Beyotime, P0256) at 4°C overnight. Membranes were washed with TBST for 10 min (3 times) and then incubated with secondary antibodies diluted in TBST for 1h at room temperature. After washed 3 times with TBST (10 min each), the chemiluminescent signals were analyzed with Clix imaging system (Clix Science Instruments).

377

378

379 **Propidium iodide assays.** HEK293T cells were seeded in 24-well plates and transfected with
380 indicated plasmids for 24 h. After that, the medium was collected for cytotoxicity assays. The cells
381 were washed for 3 times gently and stained with propidium iodide (BD Bioscience, 556463) and
382 then analyzed with fluorescence microscopy.

384 **Flow cytometry assays.** Cells were harvested using trypsin and washed with PBS 3 times gently
385 and then stained with propidium iodide (BD Bioscience, 556547) according to the manufacturer's
386 instructions. The cells were analyzed with Flow cytometer (Becton Dickinson, FACSVerse).

388 **RNA extraction and RT-qPCR.** To collect the RNA of PEDV, the medium was discarded and
389 total RNA of the cells and virus was extracted with RNA-easy Isolation Reagent (Vazyme,
390 R701-01). After measuring the concentration of extracted RNA, reverse transcription was
391 conducted with HiScript III 1st Strand cDNA Synthesis Kit (+gDNA wiper) (Vazyme, P312-02)
392 according to the manufacturer's instructions. Afterwards, cDNA samples were analyzed by qPCR
393 using ChamQ Universal SYBR qPCR Master Mix (Vazyme, P711-01). Primers used for RT-qPCR
394 were listed in Supplementary table 3.

396 **CoIP assay.** HEK293T cells seeded in 6-well plates were transfected with the specific plasmids
397 for 24 h and then cells were lysed with Cell lysis buffer for Western and IP (Beyotime, P0013)
398 containing PMSF (Beyotime, ST506) or Protease inhibitor cocktail for general use (Beyotime,
399 P1005) for 30 min on the ice. Afterwards, the lysates were centrifuged at 4 °C and the supernatants
400 were incubated with anti-Flag binding beads (Sigma, M8823) at 4 °C overnight. The binding beads
401 were then washed with TBS 5 times and then denatured in 1 × SDS-PAGE loading buffer for 10
402 min. Finally, the supernatants were analyzed with Western blotting.

404 **Confocal immunofluorescence assay.** HEK293T cells were seeded in 24-well plates on
405 coverslips and after cultured overnight indicated plasmids were transfected. At 24 h after
406 transfection, cells were washed 3 times with cold PBS and then fixed with Immunol Staining Fix
407 Solution (Beyotime, P0098) at room temperature for 30 min, following with washing 3 times with
408 PBS (2 min each). Then the cells were permeabilized with Immunostaining Permeabilization

409 Solution with Saponin (Beyotime, P0095) at room temperature for 20 min and washed with PBS 3
410 times (5 min each). After that, cells were blocked with QuickBlock Blocking Buffer for Immunol
411 Staining (Beyotime, P0260) at room temperature for 60 min, and then incubated with primary
412 antibody (anti-MYC, Sigma, C3956) at 4 °C overnight. After washing 3 times with PBS (3 min
413 each), the cells were incubated with the secondary antibody (Goat Anti-Rabbit IgG Alexa Fluor
414 568, Abcam, ab175471) at 37 °C for 60 min in the dark and then they were washed 3 times with
415 PBS (5 min each). Nuclei were stained with DAPI (Beyotime, C1002) for 5 min and then cells
416 were washed 4 times with PBS (5 min each). The cells were then analyzed with a Laser confocal
417 microscopy (Olympus, IX81-FV1000).

418

419 **Sequence alignment.** We collected amino acid sequence of pGSDMD and other GSDMD
420 homologs from human (GenBank accession NP_001159709.1) and mouse (GenBank accession
421 6N9N_A), and the amino acid sequence of Nsp5 of PEDV and Nsp5 of PDCoV (GenBank
422 accession AKQ63081.1), SARS-CoV-2 (GenBank accession NC_045512) and MERS-CoV
423 (GenBank accession NC_038294). SnapGene software were used to perform the
424 multiple-sequence alignment.

425

426 **Statistical analysis.** All experiments were repeated three times or more. Data are presented as
427 mean $\pm$ SD and analyzed by the two-tailed Student's *t* test or one-way ANOVA followed by
428 Tukey's multiple comparisons test by Prism software (GraphPad). The differences were
429 considered significant when $p < 0.05$ (*), $p < 0.01$ (**), and $p < 0.001$ (***).

430

431 **Acknowledgements**

432 This work was financially supported by grants from the National Natural Science Foundation of
433 China (32072817), the National Key Research & Development Program of China
434 (2016YFD0500102), the Zhejiang Provincial Key R&D Program of China (2021C02049), the

437 the Fundamental Research Funds for the Central Universities of China (2020XZZX002-20).

We thank Dr. Ying Shan in the Shared Experimental Platform for Core Instruments, College of Animal Sciences, Zhejiang University for assistance with analysis of laser confocal microscopy imaging.

Author contributions

F. Shi, W. Fang, X. Li and Q. Lv conceived the overall scope of the project. F. Shi and Q. Lv designed and performed the majority of the experiments. J. Gu and T. Wang performed the viral culture and the preparation of polyclonal antibodies; J. X helped with quantitative real-time PCR; W. Xu assisted Q. Lv in Flow cytometry; Y. Shi, X. Fu and T. Yang assisted Q. Lv in plasmid construction and confocal immunofluorescence assay; Y. Yang helped with statistical analysis; L. Zhuang assisted F. Shi and Q. Lv wrote the manuscript. All authors discussed the results and reviewed the manuscript.

Fig. 3 L295/Y378/A382 are the key sites for pGSDMD autoinhibition. (A) HEK293T cells were mock transfected or transfected with plasmids encoding pGSDMD-FL, pGSDMD-p30 and its point mutants. At 24 h after transfection, the supernatants were collected and analyzed for LDH levels. n.s., $P > 0.05$. (B) HEK293T cells were mock transfected or transfected with plasmids encoding pGSDMD-FL and pCaspase-1, pGSDMD-p30, hGSDMD-FL and hCaspase-1, hGSDMD-p30. Meanwhile, cells were treated with mock, NSC (final concentration of 25 μ M) or NSA (final concentration of 10 μ M). At 24 h after transfection, the supernatants were collected and analyzed for LDH levels. *, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$. (C) The structure of modeled pGSDMD-FL and enlarged view of the boxed area. (D and E) HEK293T cells were mock transfected or transfected with plasmids encoding pGSDMD-p30, pGSDMD-FL and its point mutants. At 24 h after transfection, the supernatants were collected and analyzed for LDH levels. **, $P < 0.01$; ***, $P < 0.001$.

Fig. 4 PEDV Nsp5 associates with and cleaves pGSDMD. (A) Vero cells were mock transfected or transfected with plasmids encoding pGSDMD-p30 and pGSDMD-FL. At 4 h after transfection, the cells were mock infected or infected with PEDV at an MOI of 0.1. After 36 h, the supernatants were collected and analyzed for LDH levels. n.s., $P > 0.05$; *, $P < 0.05$. (B) Vero cells were transfected with plasmids encoding pGSDMD-p30 and pGSDMD-FL. An empty vector was used as a control. At 24 h after transfection, the cells were infected with PEDV at an MOI of 0.5. After 24 h, total RNA was extracted and the viral RNA levels of PEDV were evaluated by quantitative real-time PCR using SYBR green. Data were expressed as fold change of the PEDV mRNA level relative to that of the control vector. **, $P < 0.01$. (C) HEK293T cells were transfected with plasmids encoding PEDV-Nsp5 and pGSDMD-p30, or co-transfected with these two plasmids. At 24 h and 36 h after transfection, the supernatants were collected and analyzed for LDH levels. *, $P < 0.05$. (D) HEK293T cells were transfected with plasmids as shown. At 24 h after transfection, the cells were then processed for Western blotting. (E) HEK293T cells were transfected with plasmids encoding p3×Flag-N-GSDMD-FL and various dose of MYC-Nsp5. After 24 h, cells were lysed for Western blotting. (F) HEK293T cells were transfected with plasmids encoding GFP-pGSDMD and MYC-Nsp5 for 24 h, and then MYC-Nsp5 were labeled with specific primary antibodies and secondary antibodies (red). Cell nuclei were stained with DAPI (blue). The

619 fluorescent signals were observed with confocal immunofluorescence microscopy. HEK293T cells
620 were transfected with plasmids encoding GFP-pGSDMD or MYC-Nsp5 as control. (G) HEK293T
621 cells were transfected with plasmids encoding MYC-Nsp5 and vector or p3×Flag-N-GSDMD-FL
622 for 24 h, followed by CoIP with anti-Flag binding beads and a Western blotting analysis. (H)
623 HEK293T cells were transfected with plasmids encoding p3×Flag-N-GSDMD-FL and wild-type
624 PEDV Nsp5 or its protease-defective mutants (H41A and C144A). After 24 h, cells were lysed for
625 Western blotting. (I) HEK293T cells were transfected with plasmids as shown, followed by CoIP
626 with anti-Flag binding beads and a Western blotting analysis.

627

628 **Fig. 5 PEDV Nsp5 cleaves pGSDMD at residue Q193.** (A) Logo analysis of the predicted
629 cleavage site of PEDV Nsp5. (B) HEK293T cells were transfected with plasmids encoding
630 MYC-Nsp5 and p3×Flag-N-GSDMD-FL or its mutant, including p3×Flag-N-GSDMD-FL-Q193A,
631 p3×Flag-N-GSDMD-FL-Q195A, p3×Flag-N-GSDMD-FL-Q197A. Cells were then lysed after 24
632 h and evaluated by Western blotting. (C) Cartoon diagram of pGSDMD structure and the cleavage
633 site by PEDV Nsp5. (D) HEK293T cells were mock transfected or transfected with the plasmids
634 encoding pGSDMD-FL, pGSDMD-p30, pGSDMD-1-193, pGSDMD-194-279 and
635 pGSDMD-194-279. After 24 h, the supernatants were collected and analyzed for LDH levels and
636 the cell were then processed for Western blotting. **, P < 0.01. (E) HEK293T cells were
637 transfected with the plasmids as shown. After 24 h, the cells were then processed for Western
638 blotting. (F) HEK293T cells were transfected with plasmids encoding HA-caspase-1 and vector,
639 pGSDMD-FL, pGSDMD-1-193, pGSDMD-194-488, or pGSDMD-194-279, followed by CoIP
640 with anti-Flag binding beads and a Western blotting analysis. (G) Vero cells were transfected with
641 plasmids encoding pGSDMD and its variants as indicated. At 24 h after transfection, cells were
642 infected with PEDV at an MOI of 0.5. After 24 h, total RNA was extracted, and the viral RNA
643 level of PEDV were evaluated by quantitative real-time PCR using SYBR green. **, P < 0.01.

644

645 **Fig. 6 The T239 and F240 amino acids of the N terminus of pGSDMD are necessary for its**
646 **induced pyroptosis.** (A and B) HEK293T cells were transfected with plasmids encoding
647 pGSDMD-FL and its variants. After 24 h, the supernatants were collected and analyzed for LDH
648 levels, and the cells were dyeing with PI. ***, P < 0.001; **, P < 0.01. (C) HEK293T cells were

transfected with plasmids encoding pGSDMD-p30 and its point mutants. After 24 h, the supernatants were collected and analyzed for LDH levels. **, $P < 0.01$. (D) Vero cells were transfected with the plasmids encoding pGSDMD-FL, pGSDMD-p30 and its point mutants (pGSDMD-p30-T239D, pGSDMD-p30-F240D). At 24 h after transfection, cells were infected with PEDV at an MOI of 0.5. After 24 h, total RNA was extracted, and the viral RNA level of PEDV were evaluated by quantitative real-time PCR using SYBR green. ***, $P < 0.001$.

655

Fig. 7 GSDMD is a common target of Nsp5 of different coronaviruses. (A) Structure alignment of CoVs Nsp5. Red arrows indicate conserved enzymatic proteolysis residues His41 and Cys144. The 3D structures were derived from the Protein Data Bank with the following accession numbers: PEDV, 4XFQ; SARS-CoV-2, 7BUY; MERS-CoV, 5WKK; PDCoV, 6JIJ. (B) HEK293T cells were transfected with plasmids encoding p3×Flag-N-GSDMD-FL and Nsp5 encoded by PEDV, PDCoV, SARS-CoV-2, MERS-CoV. After 24 h, cells were lysed and detected by Western blotting. (C) HEK293T cells were transfected with plasmids encoding pGSDMD and wild-type PDCoV Nsp5 or its protease-defective mutants (H41A and C144A). After 24 h, cells were lysed for Western blotting. (D and E) HEK293T cells were transfected with plasmids encoding pGSDMD and wild-type SARS-CoV-2 Nsp5 or its protease-defective mutants (H41A and C145A), hGSDMD and wild-type SARS-CoV-2 Nsp5 or its protease-defective mutants (H41A and C145A). After 24 h, cells were lysed for Western blotting. (F and G) HEK293T cells were transfected with plasmids encoding pGSDMD and wild-type MERS-CoV Nsp5 or its protease-defective mutants (H41A and C148A), hGSDMD and wild-type MERS-CoV Nsp5 or its protease-defective mutants (H41A and C148A). After 24 h, cells were lysed for Western blotting.

671

Figure 8 Homology modeling of Nsp5 of different CoVs with the cleaved GSDMD peptide substrate. The molding structure of PEDV Nsp5 (PDB accession number 4XFQ) (A), SARS-CoV-2 (PDB accession number 7BUY) (B and E), MERS-CoV (PDB accession number 5WKK) (C and F), PDCoV (PDV accession number 6JIJ) (D) combined with the cleaved pGSDMD peptide substrate GAVSLQ(193)↓GQGQGH (downward arrows indicates cleavage sites) (A, B, C and D) and hGSDMD peptide substrate GATCLQ(193)↓GEGQGH (downward arrows indicates cleavage sites) (E and F) were analyzed using PyMOL software.

679 **Figure 9** Diagram of CoVs antagonize GSDMD-mediated pyroptosis.

680

681 **Extended Data Figure 1** Alignment of the amino acid sequence of pGSDMD and other GSDMD
682 homologs from human (GenBank accession NP_001159709.1) and mouse (GenBank accession
683 6N9N_A).

684

685 **Extended Data Figure 2** HEK293T cells were mock transfected or transfected with plasmids
686 encoding p3×Flag-N-GSDMD-FL. At 24 h after transfection, cell lysates were analyzed by
687 Western blotting with antibodies for Flag, β-actin and the polyclonal antibody directed against
688 pGSDMD prepared in our laboratory.

689

690 **Extended Data Figure 3** HEK293T cells were mock transfected or transfected with plasmids as
691 shown. At 24 h after transfection, the cells were processed and staining with PI, and then analyzed
692 with Fluorescence microscopy (A) and Flow cytometry (B).

693

694 **Extended Data Figure 4** HEK293T cells were mock transfected or transfected with the plasmids
695 encoding EGFP-GSDMD-FL, EGFP-GSDMD-p30, EGFP-GSDMD-1-193,
696 EGFP-GSDMD-194-279, EGFP-GSDMD-194-488. After 48 h, the supernatants were collected
697 and analyzed for LDH levels, and the cells were analyzed with Fluorescence microscopy. *, P <
698 0.05.

699

700 **Extended Data Figure 5** HEK293T cells were transfected with plasmids encoding pGSDMD-p30
701 and its point mutants. After 24 h, the cells were dyeing with PI and analyzed with Fluorescence
702 microscopy.

703

704 **Extended Data Figure 6** Alignment of the amino acid sequence of Nsp5 of PEDV with Nsp5 of
705 PDCoV (GenBank accession AKQ63081.1), SARS-CoV-2 (GenBank accession NC_045512) and
706 MERS-CoV (GenBank accession NC_038294).
