21

22 **ABSTRACT.** *Meringosphaera* is an enigmatic marine protist without clear phylogenetic
23 affiliation, but it has long been suggested to be a chrysophytes-related autotroph.
24 Microscopy-based reports indicate that it has a worldwide distribution, but no sequence data
25 exists so far. We obtained the first 18S rDNA sequence for *M. mediterranea* (identified using
26 light and electron microscopy) from the West Coast of Sweden. Observations of living cells
27 revealed granulated axopodia and up to 6 globular photosynthesizing bodies about 2 μm in
28 diameter, the nature of which requires further investigation. The ultrastructure of barbed
29 undulating spine scales and patternless plate scales with a central thickening is in agreement
30 with previous reports. Molecular phylogenetic analysis placed *M. mediterranea* inside the
31 NC5 environmental clade of Centroplasthelida (Haptista) along with additional
32 environmental sequences, together closely related to Choanocystidae. This placement is
33 supported by similar scales in *Meringosphaera* and Choanocystidae. We searched the Tara
34 Oceans 18S-V9 metabarcoding dataset which revealed four OTUs with 95.5-98.5%
35 similarity, with oceanic distribution similar to that based on morphological observations. The
36 current taxonomic position and species composition of the genus are discussed. The
37 planktonic lifestyle of *M. mediterranea* contradicts the view of some authors that centrohelids
38 enter the plankton only temporarily.
39 **Keywords:** Centrohelids; External skeleton; Heliozoa; Protists; Systematics; Ultrastructure

40

41 IN 1887, Victor Hensen, a German zoologist and the founder of planktology (Lussenhop
42 1974) reported a finding of what he described as a yellow microscopic plant with rigid
43 flexuous outgrowths (starr gewundenen ausläufer) in the plankton of the Baltic sea (von
44 Hensen 1887). A few years later, a similar organism was found by Lohmann near the coast of
45 Sicily, who erected for it the new genus *Meringosphaera* Lohmann, 1902 [1903]¹ (from
46 greek $\mu\pi\rho\upsilon\gamma\acute{\xi}$ - bristle and $\sigma\phi\alpha\epsilon\rho\alpha$ - ball, globe). According to Lohmann (1902 [1903] p.
47 68), the genus was home to unarmoured (ohne Panzer) green chromatophores-bearing cells
48 without encircling groove (Gürtelfurche), but with long bristles for floating (Schwebborsten).
49 In *M. mediterranea*—the species that was later fixed as type (Loeblich and Tappan 1963)—
50 Lohmann described four chromatophores, which had a peripheral position and a cup-like
51 shape. In contrast to the original description by Hensen, Lohmann reported green, not yellow
52 color of the chromatophores, but he considered this species an alga of undetermined origin
53 (protophyten unsioherer Stellung) (Lohmann 1902 [1903]). In addition to *M. mediterranea*,
54 Lohmann included the description of three additional species. In the following years, a dozen
55 additional species of *Meringosphaera* were described by various authors but due to a vague
56 genus diagnosis it contained a collection of unlikely related forms, most of which were later
57 transferred to other genera (see Silva (1979) for review of the taxonomic history).
58 Nevertheless, the type species—*Meringosphaera mediterranea* Lohmann, 1902 [1903]—is
59 notable and recognizable even by light microscopy (Leadbeater 1974). It is often reported
60 from marine plankton habitats worldwide (Table S1; Fig. 1). In some regions, it can be one of
61 the most common and abundant planktonic species (LeRoi and Hallegraeff 2006;
62 Thornington-Smith 1970), reaching the concentration of 8×10^4 cells l^{-1} (Booth et al. 1982).
63 *M. mediterranea* has been reported from the surface down to 125 m deep waters (micrograph
64 JRYSEM-305-020 on mikrotax.org) and demonstrated a temperature tolerance from 0 to
65 30 °C (Hallegraeff 1983; Thomsen 1982).

66 Despite the numerous reports of *Meringosphaera* worldwide, the taxonomic
67 affiliation of the genus has remained mysterious. Wille (1909) classified it within the green
68 algal family Oocystaceae, based on the presence of the green chromatophores and superficial
69 resemblance to the genera *Micractinium* and *Oocystis*. Pascher (1912; 1917; 1932) and
70 Schiller (1916; 1925) placed the genus in the yellow-green algal order Heterococcales. This
71 view was mostly based on the observation of two-layered siliceous walls in the cysts of
72 *Meringosphaera trisetata* (Pascher 1917), but this species was later shown to be a diatom
73 (Thronsdon and Zingone 1994). Schiller (1916) also studied *M. mediterranea* and showed
74 that the cells are surrounded by a rigid siliceous shell (Hulle), from which siliceous bristles
75 emerge. Each bristle arises from the low circular cup, located upward on the shell. Norris
76 (1971) studied material from the Indian Ocean and placed *Meringosphaera* in the family
77 Aurospheeraceae in Chrysophyceae, based on a “golden tinge” of the living cells.
78 Additionally, Norris provided the first ultrastructural account of the “bristles”, which were

¹ The volume with his work was issued with the year '1903' on the title page, but according to bibliographic notes of Oltmanns (1903, column 210), Zschokke (1903, p. 324), Matzdorff (1903a p. 116; 1903b p. 191), Graf zu Solms Laubach and Oltmanns (1904 column 103), and Krumbach (1907 p. 463), the actual year of its issue is 1902.

79 shown to be undulating tapering spine scales with short barbs directed towards the scale apex.
80 The “shell” in turn was described as a layer of overlapping patternless plate scales with a
81 central narrow thickening. Later, this characteristic morphology was observed and confirmed
82 in multiple additional studies of the marine plankton. Leadbeater (1974) supported a
83 chrysophycean affinity based on specimens collected in the Mediterranean sea, noting the
84 similarity of the spine and plate scales with those of the chrysophyte *Chrysosphaerella* spp.
85 Parke performed staining of the cell with dilute cresyl blue, which resulted in a rose-red color
86 suggesting the presence of chrysolaminarin reserve products, again supporting a chrysophyte
87 affiliation (personal communication of M. W. Parke in Leadbeater 1974). Moestrup (1979)
88 found similar siliceous scales near the coast of New Zealand, which he also interpreted as
89 chrysophycean affinities.

90 In the end of the XX century several authors expressed some doubt on the algal nature
91 of *Meringosphaera* and suggested its possible relationship with centrohelid heliozoans.
92 Thomsen was the first author to mention striking similarities between the scales of
93 *Meringosphaera* with the siliceous scales of centrohelid heliozoans, particularly those of
94 *Choanocystis perpusilla*—one of the first ultrastructurally studied (Petersen and Hansen
95 1960) centrohelids (personal communication of Thomsen in Moestrup (1979 pp. 65, 92).
96 Dürschmidt (1985) published an extensive study of the centrohelid scales and also noted that
97 the morphology of *Meringosphaera* plate and spine scales “indicates close affinities to the
98 heliozoa”. A similar view was expressed by Vørs (1992), who initially also suggested a
99 relationship to the centrohelid *Choanocystis* based on the scale similarity. However, in a later
100 report, Vørs and co-authors (1995) listed *Meringosphaera* among *incertae sedis* taxa and
101 only vaguely referred to this organism as heliozoan-like heterotroph. The “chromatophores”
102 were interpreted by Vørs as colored food vacuoles after preying on algae, not actual
103 organelles. Ikävalko and Gradinger (1997) also reported a heterotrophic and centrohelid-
104 related nature of this organism based on their observation of colorless living cells with no
105 detectable chlorophyll, even when studied by epifluorescence microscopy with blue light
106 excitation.

107 However, in most of the more recent publications, the suggestions of heliozoan-
108 related nature were dismissed and *Meringosphaera* is referred to as chrysophyte (Fragoso
109 2016; Hasle and Heimdal 1998; LeRoi and Hallegraeff 2006; Liu and Chen 2015; Percopo et
110 al. 2011; Scott and Marchant 2005; Viličić et al. 2002) or xanthophyte (Cărăuș 2002),
111 although sometimes also as *incertae sedis* taxon (Adl et al. 2005, 2012, 2018; Bergesch et al.
112 2008; Bosak et al. 2012). In order to clarify the systematic position of *M. mediterranea*, we
113 obtained the first 18S rDNA sequences for the genus based on several individual cells
114 collected on the West Coast of Sweden, and combined these to microscopic observations of
115 living cells and transmission electron microscopy. We unambiguously shown that
116 *Meringosphaera* belong to centrohelids, specifically to the environmental marine clade NC5.

117

118 **MATERIAL AND METHODS**

119

120 **Sampling and cell isolation**

121

122 The material for this study was obtained from marine samples collected at two stations along
123 the West Coast of Sweden: Anholt East (N 56°40'00" E 12°07'00") and Å17 (N 58°16'29" E
124 10°30'47"). Samples were collected on 17.10.2018 at Anholt, and on 11.11.2018 and
125 07.12.2018 at Å17 by SMHI (Swedish Meteorological and Hydrological Institute) on the R/V
126 Aranda, simply by collecting about 1 liter of surface water with a bucket. The water salinity
127 at the sampling sites was around 27 psu at Anholt E and 33 psu at Å17. The water
128 temperature was around 13 degrees in October, 10 degrees in November and around 8
129 degrees in December. The samples were transported to the laboratory on cooling packs in a
130 foam plastic box. In the laboratory, the samples were passed through a 5–15 µm pore size
131 paper membrane (VWR, Cat No. 516-0813) by gravity filtration to avoid damaging the cells–
132 *M. mediterranea* cells are very fragile. The filters were washed in a 60 mm plastic Petri dish
133 with 10 ml of filter-sterilized marine water. The dishes were scanned for characteristic *M.*
134 *mediterranea* morphology using a 40 × lense of the Nikon Eclipse Ts2R inverted
135 microscope, equipped with phase contrast. The detected cells were photographed with a
136 Nikon D5300 camera and collected with a tapered Pasteur pipette. In general, we observed
137 between 10 and 50 *Meringosphaera* cells per dish using this approach. The collected cells
138 were placed on a glass slide for microscopy or frozen in 200 µl PCR tubes for molecular
139 experiments. The DIC and fluorescent images were obtained from temporary preparations
140 observed with Leica DMRXE microscope.

141

142 **Electron microscopy**

143

144 Preparation of the scales for scanning electron microscopy was conducted according to
145 Zlatogursky (2014). The cells were air-dried on the surface of a coverslip. The coverslips
146 were washed with distilled water, attached to specimen stubs, gold-coated and observed with
147 a Zeiss Auriga working station operated at 5 kV. Scales were measured in EM images.

148

149 **Genome amplification and PCR**

150

151 Frozen single cells in PCR tubes were thawed and subjected to lysis and multiple
152 displacement amplification (MDA) using the REPLI-g UltraFast Mini kit (Qiagen) following
153 the manufacturer's instructions. The product of the MDA reactions were 10X diluted and
154 used as templates in PCR amplification of the 18S rDNA gene using broad eukaryotic
155 primers: PF1 5'-TGCGCTACCTGGTTGATCCTGCC-3' (Keeling 2002) and FAD4 5'-
156 TGATCCTTCTGCAGGTTACCTAC-3' (Deane et al. 1998; Medlin et al. 1988). One of the
157 obtained PCR products was purified with ExoProStar 1-Step kit (GE Healthcare US77702)
158 and Sanger-sequenced directly at Macrogen (Netherlands). The obtained sequence was
159 deposited in GenBank under accession number ##### (to be inserted prior to publication).

160

161 **Phylogenetic analyses**

162

163 The sequence was quality-checked for ambiguous bases in Chromas Pro, and
164 manually aligned using SeaView v. 4.3.5 (Gouy et al. 2010) on an available alignment

165 including a broad diversity of eukaryotes. Then 1531 unambiguously aligned positions were
166 selected for phylogenetic analysis. Initial Maximum Likelihood (ML) analyses indicated that
167 *M. mediterranea* is a centrohelid, thus in subsequent analyses we included a broad diversity
168 of sequences for this group. The final tree reconstruction was done using RAxML v. 8
169 (Stamatakis 2014), using the GTR model and 4 gamma categories to take into account across
170 sites rate heterogeneity, after model selection in Modeltest (Posada and Crandall 1998).
171 Assessment of clade support was performed with bootstrap resampling using 1,000 replicates.

172

173 **Search against TARA**

174

175 The search against Tara oceans OTU 18S V9 v. 2 database was performed using the Ocean
176 Barcode Atlas website (<http://oba.mio.osupytheas.fr/>), using our complete 18S rDNA as a
177 query and the vsearch algorithm with 98% similarity threshold.

178

179 **RESULTS**

180

181 **Light microscopy**

182

183 The light microscopic description is mostly based on material collected from Anholt
184 sampling site. The observed *M. mediterranea* cells were 4–9 µm in diameter, typically with
185 6–9 prominent axopodia and up to 13 undulating spine scales per optical section (Fig. 2C, D).
186 Axopodia were distinctively granulated, 6–16 µm long, usually exceeding the cell diameter
187 by 1.5–2 times. Cells without visible axopodia were sometimes also observed. The cells were
188 always motionless, passively attached to the substratum or floating. All the specimens
189 observed had a yellow-greenish tinge, containing several globular photosynthesizing bodies.
190 One cell was squeezed with a coverslip, which revealed 6 distinct photosynthesizing bodies
191 of about 2 µm in diameter (Fig. 2A). The chlorophyll autofluorescence emanating from the
192 photosynthesizing bodies was clearly visible when subjected to fluorescence microscopy with
193 blue excitation and green-red emission (Fig. 2B).

194

195 **Electron microscopy**

196

197 The skeletal elements of the cells (plate scales and spine scales) from Å17 (mostly) as well as
198 from Anholt sampling points were studied with scanning electron microscopy (Fig. 3). The
199 spine scales were typically 16–25 µm long, but in one case a single 31 µm giant spine scale
200 was observed. The shaft of each scale with 9–13 undulations was covered with barbs (Fig.
201 3A, B). Usually, there were 1–3 longer barbs, about twice longer than the shaft diameter at
202 the proximal part of the scale (Fig. 3C) and multiple (15–24) shorter barbs distributed in a
203 helicoidal pattern along the whole scale length. Shorter barbs were flattened, triangular, and
204 slightly curved in the direction of the scale tip. Spine scale shafts were hollow inside with
205 internal septa, which seemed to be located at the inflection points between undulations. The
206 bases of the spine scales were convex, with a single indentation and multiple (10–13) short

207 teeth along the margin. The plate scales were patternless, oval 1.8–3.2 × 1.4–2.1 μm, with a
208 short central thickening.

209

210 **Molecular phylogeny**

211

212 A good quality sequence of the 18S rDNA gene of 1720 bp was obtained from SAG SC462
213 from Anholt, which we considered the first sequence for the genus *Meringosphaera* (see
214 discussion). A comparison in GenBank by BLASTn for highly similar sequences returned
215 only unnamed environmental sequences belonging to centrohelids. The best environmental
216 hit was KF130174 with 99.65% similarity and the best named hit - *Chlamyaster sterna*
217 KY857824 with 93.62% similarity. In order to place this sequence in a phylogenetic context,
218 a tree reconstruction including a broad selection of centrohelid taxa was performed. This
219 analysis recovered a moderately supported position (81% bootstrap support) of the sequence
220 within the NC5 environmental clade of Pterocystida (Fig. 4), following the environmental
221 clade nomenclature of Cavalier-Smith and Chao (2012) and Shoshkin et al. (2018). The NC5
222 clade included several additional environmental sequences (of a marine plankton origin
223 wherever specified) and was sister to the Ch1 clade, containing the closest group with named
224 species Choanocystidae.

225

226 **Metabarcoding dataset search**

227

228 We investigated the oceanic distribution of the *Meringosphaera* sequence derived from SAG
229 SC462. A search against the Tara Oceans 18S V9 v. 2 metabarcoding dataset returned four
230 hits (OTUs 18Sv.9-v.2 346365; 18Sv.9-v.2 557845; 18Sv.9-v.2 1004; 18Sv.9-v.2 35493),
231 which had a global distribution (Fig. 5), maximal relative abundances in surface waters, but
232 were also quite common in the vicinity of the deep chlorophyll maximum. In general, these
233 OTUs had a low relative abundance, representing at most $2.33e^{-3}$. In the mesopelagic zone,
234 the OTUs were less abundant but still present worldwide. The temperature tolerance range
235 was high, varying from 2 to 33 °C, while salinity tolerance was quite narrow, varying between
236 32 and 41 ppt and never below 28 ppt (Fig. 5). This matched our own observation that
237 *Meringosphaera* occurred frequently on the Swedish West coast where the salinity is at about
238 33 ‰, but could never be detected in samples from the Baltic Sea proper with a much lower
239 salinity. The OTUs were found in all the size fractions, except the finest (0.8–3 μm).

240

241 **DISCUSSION**

242

243 The morphological analysis by light microscopy and the ultrastructure of the specimens
244 studied strongly suggests that these organisms correspond to *Meringosphaera mediterranea*.
245 Most of the species described under the genus name *Meringosphaera* have eventually found
246 their homes in other genera, considered synonymous or too distinct and/or poorly described
247 to safely keep them in the genus (Table 1). In fact, Silva (1979) proposed that the species
248 diversity of the genus *Meringosphaera* should be restricted to *M. mediterranea* and *M.*
249 *aculeata* Pascher, 1932. *M. aculeata*, despite the considerable similarity to *M. mediterranea*,

250 is distinct in having fewer undulations per scale and very long barbs, which Wulff (1919) was
251 able to detect with light microscopy. His fig. 14 taf. II is in a good agreement with type 2
252 scales on scanning electron micrographs (fig. 4 and 5 of Norris (1971)), as well as with the
253 micrograph JRYSEM-317-330 published on the microtax.org website. Other micrographs,
254 published under the name *M. mediterranea* are quite heterogeneous and probably represent
255 several closely related species. For example, the morphotype with stellate base of the spine
256 scale is very distinctive (fig. 3 and 8 of Norris (1971); fig. 2 of Vørs and co-authors (1995);
257 micrograph JRYSEM-260-16 on microtax.org). The cells in our study were similar to typical
258 *M. mediterranea* as in fig. 1 of Norris (1971); Plate 4 B–F of Leadbeater (1974); fig. 6 of
259 Vørs (1992) and many other published micrographs, both by details of the ultrastructure and
260 morphometric characters.

261 The new *M. mediterranea* sequence was clearly positioned in the environmental NC5
262 group in centrohelids. In total, the NC5 group now contains 12 environmental sequences in
263 GenBank, all marine, in addition to the new *Meringosphaera* 18S rDNA sequence. Our
264 phylogeny also suggested a weak relationship to Ch1 - a mostly environmental clade with
265 only two morphologically characterized sequences, representing the family Choanocystidae.
266 Although this relationship requires confirmation due to the low bootstrap support, it is in
267 agreement with the view of some authors (Moestrup 1979; Vørs 1992) who emphasized the
268 similarity in the scale structure between *M. mediterranea* and *Choanocystis* spp. Since
269 *Choanocystis* is a very species-rich genus with 18 described species (Mikrjukov 1995;
270 Tihonenkov and Mylnikov 2010; Zlatogursky 2010, 2014), only two of which have been
271 sequenced (Shakhkin et al. 2018), it is possible that some of the morphotypes attributed to
272 *Choanocystis* actually belong to the NC5 clade. This is even more probable for the four
273 exclusively marine species. For example, *Choanocystis antarctica* Tihonenkov et Mylnikov,
274 2010 is one of the best candidates to be closely related to *Meringosphaera* since it also has a
275 typical barb on each spine scale and each spine scale in this species possesses a single
276 undulation.

277 The search using the new *M. mediterranea* sequence against the Tara Oceans 18S V9
278 v. 2 database returned four OTUs with > 98% similarity, which we attribute to the same
279 species. The geographic distribution of these OTUs is in good agreement with the
280 morphology-based reports of *M. mediterranea*, confirming that this species is a global
281 member of the oceanic plankton communities (compare Fig. 1 and Fig. 5). The finding of a
282 global planktonic centrohelid species is at odds with the idea that centrohelids are only
283 temporarily found in the water column. Mikrjukov (2002) argued that centrohelids are
284 permanent important consumers in both freshwater and marine benthic communities but are
285 only temporarily playing key ecological roles in the plankton, usually twice a year for a
286 month. The common occurrence of *M. mediterranea* in many localities instead indicates that
287 some centrohelids at least represent permanent members of planktonic communities. Our
288 Tara Oceans search also confirmed a broad temperature tolerance as noted by Hallegraeff
289 (1983), but a salinity tolerance restricted to oceanic values (Fig. 6). Finally, the vertical
290 profile of *Meringosphaera*-related OTUs showed a distribution from the surface to
291 mesopelagic zone, with relative abundance up to $2.27e^{-3}$ at deep chlorophyll maximum, which
292 may be correlated to the presence of photosynthetic bodies in this species (Fig. 5, 6). The
293 nature of these photosynthetic bodies is one of the most outstanding questions regarding

294 *Meringosphaera*, but unfortunately we failed to obtain sequence data that could help identify
295 their origin. These bodies could correspond to transient associations such as kleptoplasts or
296 facultative symbionts, stable endosymbionts, or even permanent photosynthetic organelles.
297 Regardless of the final answer on these bodies, here we've undoubtedly placed an important
298 player in the marine planktonic ecosystem to its correct phylogenetic home.

299

300 **ACKNOWLEDGEMENTS**

301

302 This study was supported by a scholarship from Carl Tryggers Stiftelse to VZ (PI: FB) and
303 the Russian Science Foundation grant no. 20-74-10068. Equipment of the core facility centers
304 "Resource Center for Nanotechnology", "Development of molecular and cell technologies",
305 "Computing center SPbU" and "Culturing of microorganisms" of Saint Petersburg State
306 University was applied. FB was supported by a grant from Science for Life Laboratory.
307 Authors are grateful to Ann-Turi Skjevik for providing SMHI samples.

479
480 **Fig. 1.** The map of the distribution of *Meringosphaera mediterranea*, based on literature
481 records. For detailed references see Table S1.

482
483 **Fig. 2.** *Meringosphaera mediterranea*, collected in Å17 (A, B) and Anholt (C, D) sampling
484 points. Light microscopy, general view of the living cell. **A.** Differential interference contrast
485 (DIC). **B.** The same field as in (A), fluorescent microscopy, blue excitation and green-red
486 emission filters. **C.** Phase contrast, the cell is squashed under a cover-slip. **D.** Phase contrast.
487 Undisturbed cell in a Petri dish. Abbreviations: a - axopodia; g - granules; pb -
488 photosynthesizing bodies; ss - spine scales. Scale bars 20 µm.

489

490 **Fig. 3.** *Meringosphaera mediterranea*, collected in Å17 sampling point. Scanning electron
491 microscopy. **A.** Individual spine scale. **B.** General view. **C.** Close up of plate scales and
492 spine-scales proximal parts. Abbreviations: bp - basal plate of the spine scale; br - barbs; ct -
493 central thickening of the plate scale; lbr - elongated barbs on the proximal part of the spine
494 scale; n - notch on the spine scale base; ps - plate scales; sp - spikes on the spine scale base;
495 ss - spine scales. Scale bars: **A, B** - 2 μm ; **C** - 1 μm .

496

497 **Fig. 4.** Maximum likelihood tree for 18S rDNA of 141 centrohelids and outgroup of 57
498 sequences (1531 sites; GTR; bootstrap 1,000 replic. 4 rate classes). Outgroup and support
499 values for shallow clades have been removed for clarity.

500

501 **Fig. 5.** Map of the geographic distribution of four *Meringosphaera*-related OTUs (Tara
502 Oceans 18S V9 v. 2). Circles are proportional to abundance. Plankton organismal size
503 fractions are color-coded. DCM - deep chlorophyll maximum; MES - mesopelagic zone
504 (200-1000 m); MIX - mixed layer; SRF - surface water.

505

506 **Fig. 6.** Bubble plots, representing the co-variation of four *Meringosphaera*-related OTUs
507 (Tara Oceans 18S V9 v. 2) abundance and an environmental feature at four sampling depth
508 fractions (DCM - deep chlorophyll maximum; MES - mesopelagic zone (200-1000 m); MIX
509 - mixed layer; SRF - surface water). Circles are proportional to abundance. Plankton
510 organismal size fractions are color-coded.

Table 1. The list of all the species described in the genus *Meringosphaera* and their final taxonomic homes.

Species names (chronologically)	Final destiny
<i>M. mediterranea</i> Lohmann, 1902[1903]	type, valid
<i>M. baltica</i> Lohmann, 1902[1903]	Synonym of <i>M. mediterranea</i> acc. to (Lohmann, 1908)
<i>M. divergens</i> Lohmann, 1902[1903]	Transferred to <i>Sciadosphaera</i> by (Pascher, 1938)
<i>M. hydroidea</i> Lohmann, 1902[1903]	Transferred to <i>Ophiaster</i> by (Lohmann, 1913)
<i>M. serrata</i> Lohmann, 1908	Presumable coccolithophorid acc. to (Pascher, 1932)
<i>M. radians</i> Lohmann, 1908	Transferred to <i>Apedinella</i> (Pedinellida) by (Campbell, 1973)
<i>M. henseni</i> Schiller, 1916	Presumable separate genus acc. to (Silva, 1979)
<i>M. trisetata</i> Schiller, 1916	Synonym of <i>Chaetoceros trondsenii</i> var. <i>trisetosa</i> (Bacillariophyceae) acc. to (Thronsen and Zingone, 1994)
<i>M. merzii</i> Schiller, 1925	Presumable separate genus acc. to (Silva, 1979)
<i>M. tenerrima</i> Schiller, 1925	Transferred to <i>Raphidosphaera</i> by (Silva, 1979)
<i>M. setifera</i> Schiller, 1925	Transferred to <i>Raphidosphaera</i> by (Silva, 1979)
<i>M. aculeata</i> Pascher, 1932	valid
<i>M. brevispina</i> Pascher, 1932	Transferred to <i>Raphidosphaera</i> by (Silva, 1979)
<i>M. sol</i> Pascher, 1932	Transferred to <i>Actinellipsoidion</i> (Xanthophyceae) by (Ettl, 1977)
<i>M. wulffiana</i> Pascher, 1938	Transferred to <i>Raphidosphaera</i> by (Silva, 1979)
<i>M. spinosa</i> Prescott, 1949	Not a member of <i>Meringosphaera</i> complex acc. to (Silva, 1979)
