Thermal Fogging with Disinfectant Didecyl Dimethyl Ammonium Bromide

Effectively Kills A Coronavirus, An Influenza Virus and Two Indicator Bacteria in Subzero Cold-Chain Environment

Abstract

Background: The origin of several local COVID-19 outbreaks in China in 2020 were confirmed to be frozen food or packages contaminated with SARS-CoV-2, revealing the lack of effective disinfection measures in the frozen food chain.

Objective: To evaluate the disinfection efficacy at -20°C of a recently marketed thermal fogging disinfection product, with disinfectant-antifreeze combination being didecyl dimethyl ammonium bromide (DDAB) - propylene glycol (PPG).

Method: Carriers with porcine epidemic diarrhea virus (PEDV) YN1, a coronavirus, and a swine influenza virus H1N1 (SIV-H1N1), and three indicator bacteria, *E. coli*, *S. aureus*, and *B. subtilis* endospores, were respectively placed in a -20°C freezer warehouse with or without DDAB-PPG fogging and activities of the microorganisms were tested.

Results: At -20°C, DDAB-PPG fogging, which fully settles in 3.5-4.5 hours, fully inactivated PEDV of $10^{-3.5}$ TCID₅₀/0.1ml and SIV-H1N1 of 2^6 hemagglutination titer within 15-30 min, and inactivated *S. aureus* and *E. coli* vegetative cells (10^6 /ml) within 15 or 60 min, respectively, but had little effect on *B. subtilis* spores. The bactericidal effect lasted at least 3 hours for bacteria on carrier plates and for 6 hours for airborne bacteria.

Conclusions: A practical subzero temperature disinfection technology was confirmed its efficacy in killing enveloped viruses and vegetative bacteria. It would help to meet the urgent public health need of environmental disinfection in frozen food logistics against pandemic and other potential pathogens and to enhance national and international biosecurity.

Keywords: frozen, cold-chain, disinfection, thermal fogging, coronavirus, influenza virus

42 Highlights

43

- 44 • First report of efficacy of disinfectant didecyl dimethyl ammonium bromide (DDAB) at subzero
- 45 temperatures

46

- 47 • The customized thermal fogging machine makes fine droplets of DDAB-propylene glycol (PPG) fog
- 48 which can suspend for ~4 hours at -20°C

49

- 50 • DDAB-PPG thermal fogging at -20°C effectively inactivated a coronavirus and an influenza virus

51

- 52 • DDAB-PPG thermal fogging at -20°C for effectively killed *S. aureus* and *E. coli*

53

- 54 • DDAB-PPG thermal fogging at -20°C inactivated airborne microorganism for up to 6 h

1. Introduction:

The objective of this study is to evaluate the disinfection efficacy of a thermal fogging method in a temperature for frozen foods. This is an urgent market need because SARS-CoV-2 present in frozen food ¹ or packages ² has been identified as the origin of transmission in some recent local outbreaks of COVID-19 in China.

Considering that high SARS-CoV-2 infection rate was found among meat processing plant workers³ and fishery workers ⁴ early in the pandemic, and SARS-CoV-2 can survive for a long time under cold temperatures ^{5,6}, these constitute a full cycle of human-to-frozen food-to-human transmission of SARS-CoV-2, which reveal both an important public health threat and a weakness in the disinfection procedures of the frozen food cold-chain.

As frozen temperature is inhibitory for growth of bacteria and viruses, and most food cold-chain related viral pathogens impact the gastrointestinal system and are often linked to incomplete cooking of food ⁷, and none about respiratory diseases. Routine disinfection practice has been insufficient if not absent in some critical links of the frozen food cold-chain operations. But the new finding that human respiratory viruses are transmitted via frozen food calls for a safer cold-chain with effective disinfection measures ⁸.

Facing the situation, China issued a number of technical guidances on food cold-chain disinfection ⁹, including *Technical guidance for prevention and control of COVID-19 in cold food production chain* and *Technical guidance for disinfection in cold food production chain to prevent and control COVID-19* Guidance [2020]-245 (Oct 16, 2020) ¹⁰ and *Work plan for preventive and comprehensive disinfection of imported cold-chain food* Guidance [2020]-255 (Nov 8, 2020) ¹¹. A key focus of these guidelines is preventive disinfection of food product packaging and interior surfaces of shipping containers, particularly in the frozen food import chain from port to market, instead of food content within packaging. These guidelines require disinfection be carried out at critical steps and efficacy of disinfection checked, and call for "sum up good

experience and practice in SARS-CoV-2 detection and disinfection" instead of giving specifics on how to disinfect, particularly for the frozen chain. Thus it can be said that the disinfection practices in the frozen food chain are still being explored and optimized. Many disinfection products have been used since the COVID-19 pandemic, but data are needed to support their efficacy and continued use in the frozen food cold-chain.

Therefore, we carried out disinfection efficacy study of a recently marketed disinfection product suitable for freezing temperatures. It uses a customized thermal fogging machine to deliver a disinfectant solution together with a matching fogging fluid & antifreeze. The disinfectant is didecyl dimethyl ammonium bromide (DDAB), and the fogging fluid & antifreeze is propylene glycol (PPG). DDAB is among the most widely used disinfectants worldwide and is on the recommended cold-chain disinfectant list by health authorities. Two field strain viruses from the coronavirus family and influenza virus family, and three indicator bacteria, *E. coli*, *S. aureus*, and *B. subtilis* endospore were tested in a -20°C food industry freezer warehouse. The data would support informed choices for cold-chain disinfection practice.

2. Material and Methods

2.1 Indicator bacteria

The *Escherichia coli* strain ATCC8099, *Staphylococcus aureus* strain ATCC6538 *Bacillus subtilis* spores (Guangdong Microbial Culture Collection or GDMCC1.372) were used.

2.2 Viruses

The porcine epidemic diarrhea virus (PEDV) field strain was a gift from Dr. Qigai He of Huazhong Agriculture University, and its passage and Median tissue culture infective dose (TCID₅₀) assay were carried out in Vero cells¹². The swine influenza virus (SIV) H1N1 A/S/TJ/04 strain was a gift from Dr. Meilin Jin of Huazhong Agriculture University and its passage and infectivity titer determination were carried out on embryonated eggs¹³.

109

110 2.3 Disinfectants and thermal fogging at -20°C

111 The Huanying 360 thermal fogging machine uses a didecyl dimethyl ammonium bromide (DDAB) water
 112 solution of 50g/100 ml and a 50% (v/v) propylene glycol (PPG) fogging and anti-freeze fluid with 0.1%
 113 lemon fragrance limonene. The combination is referred as HY-360 DDAB-PPG. The machine is
 114 programmable for duration of fogging. After setting up and powered on, it runs and stops automatically.
 115 The concentration of DDAB-PPG fog used in the study are listed in Table 1, which included two
 116 concentrations, ~0.4 g/m³ and ~1.0 g/m³, corresponding to ~8 or ~20 min of fogging. A photo of the
 117 fogging machine in operation is shown in Figure 1.

118

119 Table 1 Volume of the -20°C freezer warehouses and fogging doses

Disinfection experiment	Figure	Volume (m ³)	DDAB used (ml)	PPG used (ml)	DDAB (ml/m ³)	DDAB (g/m ³)
PEDV in 1 h	Figure 3	168	330	400	1.96	0.98
SIV in 1 h	Figure 3	97.44	80	120	0.82	0.41
3 bacteria in 1 h	Figure 4	97.44	80	110	0.82	0.41
3 bacteria in 1 h	Figure 4	273.83	550	600	2.01	1.00
bacteria in 8 h	Figure 5	273.83	550	600	2.01	1.00

120

121

122 Figure 1. A photo of Huanying 360-DDAB thermal fogging machine (lower right) started fogging operation in a freezer warehouse
123 (This is from a video of fogging which can be provided as supplementary data).

124

125 2.4 Evaluating the efficacy of disinfectant fogging on PEDV at -20°C

126 The PEDV virus stock was prepared to be $10^{-3.5}$ TCID₅₀/0.1ml. Carrier polystyrene plates were prepared by
127 dropping 60 µl virus stock in each clean plate and let air dry, which were placed either on the floor or on a
128 shelf in the freezer warehouse and exposed to disinfection thermal fogging for 15-60 min as indicated.

129 Some plates served as freeze-only controls. The plates were taken out, rinsed with 1.2 ml DMEM
130 (containing 2% penicillin and streptomycin), and the eluents were collected and stored at -80°C freezer for
131 TCID₅₀ assay later, which is done according to previous described method.

132

133 2.5 Evaluating the efficacy of disinfectant fogging on SIV H1N1 at -20°C

134 SIV H1N1 stock of HA titer $1 : 2^5$ was diluted 2 fold with sterile saline, polystyrene plates were prepared by
135 dropping 50 µl virus stock in each plate and let air dry. The carrier plates were placed on different locations
136 in the freezer warehouse as indicated and exposed to disinfectant thermal fogging for 15-60 min as
137 indicated. Some plates were served as freeze-only controls. The plates were taken out, each was rinsed
138 with 1.5 ml sterile saline, and the eluents were inoculated at 0.4 ml/each onto three 10-day chicken
139 embryos and cultured at 37°C for 72 h. Then the eggs were put into -20°C for 1 h, and the allantoic fluids
140 were collected, 2 fold serial diluted with saline and used for hemagglutination assay with chicken
141 erythrocytes. The highest dilution with erythrocytes agglutination was recorded as the rough HA titer of
142 that sample. To make titers from different assay runs comparable, the mean titer of the stock assayed in
143 each run was divided by 2^5 to obtain a normalization number and all the titers obtained were divided by
144 this number.

145

146 2.6 Bacteria disinfection experiments at -20°C

147 *E. coli*, and *S. aureus* were cultured in 10-20 ml TSB (Soybean-casein-digest) medium overnight in 50 ml
148 conical tubes, counted, and adjusted to 10^6 cfu/ml. For *B. subtilis* spores, dry powder were resuspended

149 with 0.85% saline, counted, and then diluted to 10^6 cfu/ml saline. Then 100 μ l each was spread on a 60 mm
150 diameter empty PS plate, let air fry in biosafety hood and then covered. Carrier plates were placed in a -
151 20°C freezer warehouse either on the floor (2 sites) or on a shelf (1.2 m height, 2 sites) at 2-3 plates each
152 site, and exposed to disinfection fog for 15-60 min as indicated.

153

154 For evaluating the disinfection effect on airborne bacteria, clean plates were placed into the freezer
155 warehouse at specified time, uncovered for 15 minutes to collect bacteria in the air, then covered, taken to
156 the lab, rinsed with 1.0 ml sterile saline. The eluents were spread onto fresh sterile TSA-agar plates at 100
157 μ l per plate and cultured overnight at 37°C for colonies counting to obtain cloning forming units (cfu).

158

159 2.7 Data analysis

160 The disinfection efficacy of DDAB fog for PEDV and the 3 bacteria were assessed by calculating the $\log_{10}$
161 $TCID_{50}/0.1\text{ml}$ or cfu and comparing fog exposed samples to the starting value or freezer only controls.
162 Reduction of $\geq 3\log_{10}$ is considered qualified. For SIV H1N1, the infectivity is measured by HA titer which is
163 expressed as $\log_2$ values. The figures were plotted with Plot2 Pro software.

164 3. Results

165 3.1 The DDAB-PPG fog produced by HY360 thermal fogging machine can suspend for several hours in the
166 air.

167
168 A series of photos were taken for the process of disinfection fogging with distance markers present (shown
169 in Figure 2). The visibility at time 0, i.e, right after the machine finished fogging, was 0 at all conditions
170 tested. It took ~3.5 h or ~4.5 h for the fogged rooms to restore visibility to > 5 meters at room temperature
171 (RT) or -20°C, respectively.

172 Figure 2 Photos of HY-360 DDAB-PPG thermal fogging in a RT room or a -20°C freezer warehouse. The high dose is ~1 g DDAB/m³,

173 low dose is ~0.4 g DDAB/m³. Time 0 h is when the machine finished fogging.

174

The long hours of suspension gives the disinfectant fog ample time to act on all surfaces exposed and arrive hard-to-reach spots. In addition, based on the settling speed (5 meter high/~3.5 h at RT) the fog droplet size can be estimated by Stokes law, which should give the droplet size around 4~6 μm^{14} .

3.2 DDAB thermal fogging has satisfactory virucidal efficacy at -20°C on PEDV and SIV-H1N1

Thermal fogging with ~1g/m³ DDAB at -20°C completely inactivated PEDV with log₁₀ TCID₅₀ titer of 3.5, and SIV H1N1 with HA titer of 2⁵. The experiment was repeated with 0.4 g/m³ DDAB for SIV H1N1, and full inactivation was achieved in all expect in 1 out of 6 sample at 15 min (Figure 3).

Figure 3 The virucidal effect of DDAB thermal fogging in a -20°C freezer warehouse. The fogging dose shown here was 1 g/m³ for PEDV (A) and 0.4 g/m³ for SIV H1N1(B). Data for 1g/m³ fogging for SIV H1N1 were all 0 after 0 min and not shown. For each data points n=8 for PEDV and n=6 for SIV H1N1.

3.3 DDAB thermal fogging at -20°C effectively disinfected vegetative bacteria cells but not spores

Thermal fogging with 1.0 g or 0.4g/m³ DDAB in a -20°C freezer warehouse produced ~5 log₁₀ reduction of bacteria *S. aureus* within 15 min for both doses, and >4 log₁₀ reduction of *E. coli* within 30 min or 60 min for the 1g and 0.4 g dose, respectively; as controls, the 60 min freezer exposure only samples had only <1.5

log₁₀ reduction. However, with *B. subtilis* spores, DDAB thermal fogging only resulted in 1-2 log₁₀ count reduction while freezer only control had similar count (Figure 4).

Figure 4 The bactericidal effect of DDAB fogging in a -20°C freezer warehouse. Each carrier plate was prepared with 10⁵ bacteria vegetative cells (*S. aureus* and *E. coli*) or spores (*B. subtilis*) at time 0. Then placed in the freezer with or without fogging. n=12 for each data point. For cfu of 0, a value of 1.2 was assigned to be plot on the log scale plot.

3.4 The disinfection effect of DDAB thermal fogging lasts for 3-6 hours

One time DDAB thermal fogging showed 3 or 5 hours of lasting effect (>3 log₁₀ reduction) on *S. aureus* and *E. coli* bacteria, respectively (Fig. 5A) and can have up to 6 hours of effect in eliminating airborne bacteria in the freezer warehouse (Fig. 5B).

208 Figure 5 The lasting bactericidal effect of DDAB fogging at -20°C. The x value corresponds to time of sample taking out of freezer.
 209 In A, the carrier plates were exposed for 1 h (n=6); in B, the sterile plates were exposed for 15 min (n=6).

210 4 Discussions

211

212 The significance of the innovation reported is that it meets practical needs of disinfection in the food cold-
213 chain industry under COVID-19 pandemic.

214

215 We here provide evidence that a practical innovation in disinfection based on optimizing existing
216 technology could meet a global unmet need in subzero cold-chain disinfection, which can help to break the
217 chain of SARS-CoV-2 transmission around the globe via cold chain so as to prevent re-emergence of the
218 disease in areas already under control, and could also help to minimize the transmission of other human
219 pathogens or bioterrorism agents though the cold-chain.

220

221 I DDAB is well known to kill viruses and bacteria by membrane disruption. However, its use in subzero
222 temperatures had not been reported before. As it has higher efficiency at room temperature than at 4°C at
223 inactivating viruses and vegetative bacteria¹⁵, it is necessary to test its disinfection efficacy at freezing
224 temperatures, which means it first has to be delivered in a form and dose that do not freeze and suitable
225 for frozen food cold-chain.

226

227 Disinfection with DDAB in subzero temperature was achieved by tailor-made optimization of thermal
228 fogging technology. Although thermal fogging technology has been widely used in plant protection,
229 vector control, disinfection and sanitation for decades, the technology usually requires optimization for
230 specific purposes, both in terms of machine engineering and chemical selection which is related to the
231 active agent to be delivered, such as pesticide or disinfectant, and the range of the fog to reach. For
232 example, a study of atomizer optimization found that structural parameters of the atomizer of a fogging
233 machine is key for the size of fog droplets, and with proper engineering, fog droplets could be controlled
234 within a narrow range of 4.5~6.5 μm ¹⁶. The fogging fluid, or solvent, is also key for fogging features
235 including fog volume and droplet size. The thermal fogging machine Huanying360 is designed and
236 optimized specifically for DDAB fogging, the combination haunting360-DDAB-PPG, the thermal fogging

237 machine plus disinfectant DDAB and fogging fluid propylene glycol, studied here was the best outcome
238 from many earlier explorations.

239

240 To our knowledge, this is a first report of efficacy of disinfectant DDAB at subzero temperatures,
241 regardless of bacteria or viruses. The two viruses tested, a coronavirus and an influenza virus, are within
242 the two most important virus families that have caused pandemics. The virucidal and bactericidal efficacy
243 of DDAB-PPG thermal fogging shown in figures 3-5 strongly support the effectiveness of the routine dose
244 ($\sim 0.4 \text{ g/m}^3$) of DDAB-PPG thermal fogging for regular disinfection of surfaces in frozen food logistics. The
245 dose can be doubled to achieve stronger and faster effect if heavy contamination is suspected.

246

247 The advantages of the technology presented in this study are summarized below.

248

249 First, thermal fogging technology disperses the disinfectants throughout the air and into hard-to-reach
250 spots to achieve dead-zone free disinfection of exposed surfaces of all angles, and it is likely to be able to
251 eliminate all airborne viruses as the fine fog droplets permeate the whole space for hours.

252

253 Second, the product uses familiar chemicals with excellent safety profile.

254 The disinfectant chosen, DDAB, is officially approved and recommended in recent disinfection guidelines
255 for SARS-CoV-2 and had many years of use in numerous products. The fogging fluid, PPG, which also
256 function as antifreeze, is often used to make artificial smoke and mists for fire safety training, theatrical
257 performances and rock concerts, and has been recognized as safe¹⁷.

258

259 Third, minimal human labor is required for using the machine-reagent product set.

260 The reagents are ready to use and no dilution with water is required which reduces workload and chances
261 for errors. Once set and powered on, the machine will run and stop automatically. As seen in Figure 1 and 2,
262 the fogging projects at least 5 meters high and fogging from a single spot can fill a room of $\sim 300 \text{ m}^3$ by

263 diffusion. For moderate spaces such as a shipping container or a truck, usually one machine operating from
264 one spot is sufficient.

265

266 Fourth, it is economic for regular disinfection in industrial use, as has been proven in room temperature
267 settings as compared to other options.

268

269 Regarding limitations of the technology, repeated fogging without cleaning could result in accumulation
270 of antifreeze PPG which at high concentrations is slippery, therefore anti-slippery measures should be kept
271 in mind in operation. In addition, the fogging machine is electrically powered, and therefore needs power
272 supply to run, which is not as mobile as diesel fueled thermal fogging machines. Different thermal fogging
273 machines can be chosen based on practical purposes and requirements.

274

275 5. Conclusions

276

277 Effective and practical subzero cold-chain disinfection of human viruses and other potential pathogens is
278 an urgent and important public health and biosecurity need of the globe at the present and into the future.
279 The HY360-DDAB-PPG fogging product reported in this study can meet this need with efficacy, safety,
280 economy and practicality.
