15   **Abstract**

16   The prefrontal cortex (PFC) is characterized by protracted maturation that extends until

17   adulthood. The cellular mechanisms controlling the early development of prefrontal circuits are

18   still largely unknown. Our study delineates the developmental cellular processes that are on-

19   going in the mouse medial PFC (mPFC) during the second and third postnatal weeks and

20   compares them to those in the barrel cortex (BC). We show that from the second to the third

21   postnatal week in both brain areas due to increased spontaneous inhibitory postsynaptic

22   currents (sIPSC) and reduced spontaneous excitatory postsynaptic currents (sEPSC) ones. Drug

23   application suggested that the increased sEPSC frequency at mPFC at P10 is due to depolarizing

24   GABA$_A$ receptor (GABA$_A$R) function. Evoked IPSC recordings revealed that the GABA$_A$R in mPFC

25   at P10 exhibits significantly depolarizing reversal potential, compared to mPFC at P20.

26   Additionally, the K-Cl co-transporter 2 (KCC2) expression is decreased in the neonatal mPFC

27   compared to the juvenile reinforcing the idea that GABA$_A$R function in the neonatal mPFC is

28   depolarizing. Furthermore, increasing GABA$_A$R activity leads to increased basal synaptic

29   response and spontaneous activity of neonatal mPFC, but not BC. Moreover, the GABAergic

30   interneurons in the neonatal mPFC exhibit immature active properties. The above

31   developmental changes in the synaptic and intrinsic properties of mPFC neurons contribute to

32   the enhanced network activity in the juvenile mPFC, compared to neonatal mPFC, using a

33   computational modeling approach, a result that was then confirmed by in vivo recordings.

34

35   **Abbreviations**

36   BC: Barrel Cortex

37   INs: Interneurons

38   KCC2: K-Cl co-transporter 2

39   NKCC1: Na^+-K^+-Cl^- cotransporter 1

40   mPFC: medial Prefrontal Cortex

41   P10: Postnatal day 10

42   P20: Postnatal day 20

43   PNs: Pyramidal neurons

44   sEPSC: spontaneous excitatory postsynaptic current

45   sIPSC: spontaneous inhibitory postsynaptic current

46   YFP: yellow fluorescent protein

47   PV: parvalbumin

48   SST: somatostatin

49

50   **Introduction**

51   During early postnatal development, major events that contribute to cortical circuit

52   maturation include spatial and temporal patterns of electrical activity, intrinsically determined

53   cell death of early postnatal cortical interneurons and the depolarizing action of the

54   neurotransmitter GABA (γ-aminobutyric acid) (Khazipov et al. 2004; Khazipov and Luhmann

55   2006; Allene et al. 2008; Brockmann et al. 2011; Ben-Ari et al. 2012; Southwell et al. 2012;

56   Khazipov et al. 2013; Kirmse et al. 2015; Mòdol et al. 2019). The developmental switch of GABA

57   action from depolarizing to hyperpolarizing results from changes in chloride co-transporter

58   expression: Na^+-K^+-Cl^- cotransporter 1 (NKCC1), the Cl^- importer, is highly expressed early in

59   development, while the expression of the co-transporter KCC2, the Cl^- exporter, increases after

60   the first postnatal week (Ben-Ari 2001; 2002; Ben-Ari et al. 2007; Ben-Ari 2012). In addition, both

61   intrinsic properties of neurons and synaptic transmission undergo dramatic changes during early

62   postnatal development in a brain-area specific manner (Kriegstein et al. 1987; McCormick and

63   Prince 1987; Burgard and Hablitz 1993; Ramoa and McCormick 1994; Bahrey and Moody 2003).

64 Most studies on these developmental changes of the GABAergic system in the cortex have

65 focused on the primary somatosensory cortex, visual cortex and hippocampus (Bartolini et al.

66 2013; Le Magueresse and Monyer 2013; Hensch 2016). The barrel cortex (BC) is part of the

67 primary somatosensory cortex and is organized vertically in columns of cells associated with

68 sensory perception (Guo et al. 2014) and horizontally in six layers of distinct cell types. In

69 contrast, cortical association areas such as the prefrontal cortex (PFC) regulate cognitive

70 functions and do not directly control sensory information (Fuster 2015). Anatomically, the

71 mouse medial PFC (mPFC) is defined as the agranular part of frontal lobe, lacking the prominent

72 granular layer IV and is divided into distinct subregions, namely infralimbic, prelimbic and

73 cingulate cortex (Heidbreder and Groenewegen 2003; Van De Werd et al. 2010). The timeline of

74 mPFC development is delayed compared to other sensory cortices, such as BC (Casey et al. 2000;

75 Best and Miller 2010; Kolb et al. 2012, Rinetti-Vargas et al., 2017). From infancy to adulthood,

76 the developing mPFC undergoes considerable transcriptional, structural and functional changes

77 (Diamond 2005; Tsujimoto 2008; Kolb et al. 2012; Schubert et al. 2014; Kroeze et al. 2017).

78 While adolescent development of prefrontal circuitry and the underlying cellular mechanisms

79 have been addressed by a large number of studies, few investigations tackled the wiring

80 processes at earlier stages (Brockmann et al. 2011; Bitzenhofer et al. 2015; 2017), in particular

81 he mPFC between the second (neonatal) and third (juvenile) postnatal week. Here, we aim to fill

82 this gap by investigating the synaptic and intrinsic properties of neonatal and juvenile mPFC

83 neurons and comparing them to those in the BC, with a primary focus on the GABAergic system.

84

85 **Methods**

86 All *in vitro* experiments with mice took place under an experimental protocol approved by the

87 Research Ethics Committee and by our Institutional Animal Care and Use Committee that has

88 been approved by the Veterinarian Authorities Office (protocol license no. 93164). Experiments

89 were carried out by trained scientists and in accordance with the 3R principles. *In vivo*

90 experiments were performed in compliance with the German laws and the guidelines of the

91 European Community for the use of animals in research and were approved by the local ethical

92 committee (015/17, 015/18).

93

94 **Animals**

95   The *in vitro* experiments were performed on male C57Bl/6J; Lhx6Tg(Cre); R26R-YFP+/+ mice

96   from animal facility of IMBB-FORTH were used. For the *in vivo* experiments, timed-pregnant

97   C57BL/6J mice from the animal facility of the University Medical Center Hamburg-Eppendorf

98   were used. The day of vaginal plug detection was defined as embryonic day (E)0.5, whereas the

99   day of birth was defined as P0. The offspring of both sexes are used for *in vivo* electrophysiology

100   recordings. All procedures were performed according to the European Union ethical standards

101   outlined in the Council Directive 2010/63EU of the European Parliament on the protection of

102   animals used for scientific purposes.

103   Mice were housed with their mothers and provided with standard mouse chow and water ad

104   libitum, under a 12 h light/dark cycle (light on at 7:00 am) with controlled temperature (21°C).

105   The P10 experimental group includes ages P9-P11 and the P20 group includes ages P19-P21, also

106   referred to as second and third postnatal weeks or neonatal and juvenile, respectively. All efforts

107   were made to minimize both the suffering and the number of animals used.

108

109   ***In vitro* extracellular recordings**

110   Slice Preparation*:* Mice (P10 and P20) were decapitated under halothane anesthesia. The brain

111   was removed promptly and placed in ice cold, oxygenated (95% O_2 –5% CO_2) artificial

112   cerebrospinal fluid (aCSF) containing (in mM): 125 NaCl, 3.5 KCl, 26 $NaHCO_3$, 1 $MgCl_2$ and 10

113   glucose (pH = 7.4, 315 mOsm/l). The brain was blocked and glued onto the stage of a vibratome

114   (Leica, VT1000S). Rostrocaudal coronal slices (400 μm thick) containing either the mPFC

115   (prefrontal cortex) or the BC (barrel cortex) region were selected and transferred to a submerged

116   chamber, which was continuously superfused with oxygenated (95% O_2 –5% CO_2) aCSF

117   containing (in mM): 125 NaCl, 3.5 KCl, 26 $NaHCO_3$, 2 $CaCl_2$, 1 $MgCl_2$ and 10 glucose (pH = 7.4, 315

118   mOsm/l) at room temperature (RT). The slices were allowed to equilibrate for at least 1 h in this

119   chamber before recordings began. Slices were then transferred to a submerged recording

120   chamber, continuously superfused with oxygenated (95% O_2 –5% CO_2) aCSF (same constitution

121   as the one used for maintenance of brain slices) at RT during recordings.

122   Data Acquisition: Electrophysiological recordings were performed in all experimental groups

123   under the same conditions as described below. Pulled glass micropipettes were filled with NaCl

124   (2M) and placed in layers II/III of PFC and BC. Platinum/iridium metal microelectrodes (Harvard

125   apparatus United Kingdom, 161 Cambridge, United Kingdom) were placed on layer II/III of the

126   mPFC and the BC, about 300 μm away from the 1MΩ recording electrode, and were used to

127   evoke field excitatory postsynaptic potentials (fEPSPs). Local field potentials (LFPs) were

128   amplified using a headstage with selectable high pass filter of 30 Hz to remove any offsets

129   coupled to a Dagan BVC-700A amplifier, amplified 100 times and low-pass filtered at 1-kHz. A

130   notch filter was used to eliminate line frequency noise at 30 Hz. Signals were digitized using the

131   ITC-18 board (InstruTech, Inc.) on a PC with custom-made procedures in IgorPro (Wavemetrics,

132   Inc.) and stored on a PC hard drive. All voltage signals were collected at a sampling frequency of

133   100 kHz (fs = 100 kHz).

134   For evoked fEPSPs, the electrical stimulus consisted of a single square waveform of 100 μs

135   duration given at intensities of 0.1– 0.3 mA (current was increased from 0.1 mA to 0.3 mA, with

136   0.1 mA steps) generated by a stimulator equipped with a stimulus isolation unit (World Precision

137   Instruments, Inc.). The effect of $GABA_AR$ activation was investigated by bath application of 2 μM

138   Diazepam ($GABA_AR$ agonist). Diazepam was acquired from the Pharmacy of the University

139   General Hospital in Heraklion as a 5 mg/ml solution and was diluted in aCSF during recordings.

140   Other drugs used include CNQX (10μM), AP5 (50μM) and bumetanide (10μM) (Tocris). For

141   spontaneous activity recordings, 20 5-sec recordings were acquired without any stimulation.

142   Data Analysis: Data were analyzed using custom-written procedures in IgorPro software

143   (Wavemetrics, Inc.). No additional high-pass filters were applied to the raw data. For evoked

144   recordings, the peak values of the fEPSP were measured using the minimum value of the synaptic

145   response (4–5 ms following stimulation) and were compared to the baseline value prior to

146   stimulation. Both parameters were monitored in real- time in every experiment. A stimulus–

147   response curve was then plotted using stimulation intensities between 0.1 and 0.8 mA, in 0.1

148   mA steps. For each different intensity level, two traces were acquired and averaged.

149   To identify spontaneous activity events, the acquired spontaneous activity voltage signals of 5

150   seconds' duration were decimated (down-sampled) by a factor of 10 and the standard deviation

151   σ_b of background signal was calculated in the 'quiet' part of each voltage response trace. To

152   identify the 'quiet' period, each 5sec trace was split into 100msec increments and the range of

153   voltage deflection was computed in each increment. The 'quiet' part of the LFP trace was the

154   100msec increment with the smallest σ_b value. As a spontaneous event, any voltage response

155   larger than $4 \cdot \sigma_b$ was identified. We calculated the frequency of spontaneous events by

156   measuring the number of spontaneous events divided by the duration of the trace (5s). The

157   frequency was calculated in 20 consecutive 5-sec traces and then averaged for each condition

158   animal. The spontaneous events do not correspond to spiking of individual neurons, they rather

159   reflect population spikes.

160

161   ***In vitro* patch-clamp recordings**

162   Slice Preparation: Mice were decapitated under halothane anesthesia. The brain was removed

163   immediately and coronal slices of mPFC and BC (300–350 μm thick), using a vibratome (Leica,

164   VT1000S, Leica Biosystems) were prepared from mice at the ages of P10 and P20 in ice-cold

165   oxygenated (95% O_2 - 5% CO_2) modified choline-based aCSF (in mM) 0.5 $CaCl_2$, 7 mM $MgSO_4$;

166   NaCl replaced by an equimolar concentration of choline). Slices were incubated for 30min at

167   32°C in an oxygenated normal aCSF containing (in mM): 126 NaCl, 3.5 KCl, 1.2 NaH_2PO_4, 26

168    $NaHCO_3$, 1.3 $MgCl_2$, 2.0 $CaCl_2$, and 10 D-glucose, pH 7.4, 315 mOsm/l. Slices were allowed to

169   equilibrate for at least 30 min at RT before being transferred to the recording chamber. During

170   recordings, slices were perfused at a rate of 4 ml/min with continuously aerated (95% O_2-5%

171   CO_2) normal aCSF at RT.

172   Data Acquisition: Neurons were impaled with patch pipettes (5–7 MΩ) and recorded in the

173   whole-cell configuration, either in the current-clamp or voltage-clamp mode. For current-clamp

174   experiments, the composition of the intracellular solution was: 130 mM K-MeSO$_4$, 5 mM KCl, 5

175   mM NaCl, 10 mM HEPES, 2.5 mM Mg-ATP, and 0.3 mM GTP, 265–275 mOsm, pH 7.3. For voltage-

176   clamp experiments, the composition of the intracellular solution was: 120 mM Cs-gluconate,

177   20mM CsCl, 0.1 mM $CaCl_2$, 1 mM EGTA, 0.4 mM Na-guanosine triphosphate, 2mM Mg-adenosine

178   triphosphate, 10 mM HEPES. No correction from liquid junction potential was applied between

179   the pipette and the aCSF. Whole-cell measurements were low-pass filtered at 5 kHz using an

180   Axopatch 200B amplifier (Molecular Devices, Inc). Recordings were digitized with the ITC-18

181   board (Instrutech, Inc) on a PC using custom-made codes in IgorPro (Wavemetrics, Inc). All

182   signals were collected at a sampling frequency of 20kHz.

183   Data Analysis: Data were analyzed using custom-written codes in IgorPro software

184   (Wavemetrics, Inc.). For passive membrane properties, the resting membrane potential (RMP,

185   mV) was measured within 3 min after establishing the whole-cell configuration, and monitored

186   throughout the experiment. To measure input resistance, a 500ms step-pulse protocol was used

187   with current stimulation from -200pA to +50pA. The input resistance (R_{in}, MΩ) was measured by

188   plotting the steady-state voltage deflection in an I-V plot and calculating the slope of the best fit

189   line curve ($R_{in}=V/I$). The τ_m (membrane time constant, ms) was obtained by fitting a single

190   exponential curve to the voltage deflection at -50pA, and the membrane capacitance (C_m) was

191   calculated using the formula $C_m = \tau_m / R_{in}$. In addition, the number of spikes generated in response

192   to a 500ms step-pulse range from +100pA to +300pA was measured.

193   To measure action potentials (APs) properties, we applied small supra-threshold 5ms step-pulse

194   currents to the cell from -65mV. The active properties were measured at the minimum current

195   stimulation (Rheobase, pA) that generated an AP. The AP threshold (mV) was calculated by

196   taking the first derivative of the voltage trace, defining a threshold and identifying the voltage

197   level at that time point. The rate of rise of the AP (dV/dt, mV/ms) was the maximum value of

198   that first derivative trace. The AP amplitude (mV) was defined as the voltage difference between

199   AP threshold and AP peak. The AP duration (ms) was calculated by the full width of the waveform

200   at the half maximal amplitude (half-width). The fast afterhyperpolarization (fAHP) minimum

201   (mV) was defined as the minimum voltage right after the AP. The fAHP amplitude (mV) was

202   calculated as the difference between the AHP minimum and the AP threshold. The fAHP time

203   (ms) was defined as the time duration from the time point of AP threshold to the fAHP minimum.

204   Voltage-clamp/spontaneous IPSC and EPSCs

205   The composition of our intracellular solution resulted in chloride reversal potential of -60mV and

206   Na^+/K^+ reversal potential of +10mV. This allowed for measurements of spontaneous excitatory

207   postsynaptic currents (sEPSCs) to be recorded at -60mV and of spontaneous inhibitory

208   postsynaptic currents (sIPSCs) to be recorded at +10mV. Automatically selected events were

209   subsequently visually monitored to discard erroneously included noise. The events showing only

210   single peaks were selected for kinetics analysis. All currents detected from every single neuron

211   were averaged. The peak amplitude was calculated as the maximum current value. The time

212   constant of the decay phase was detected by curve fitting with a single exponential decay

213   function.

214   Evoked IPSC recordings: To investigate eIPSCs and the reversal potential, a stimulating electrode

215   was positioned 100μm away from the recording electrode at the border between layer I and

216   layer II. The current used for stimulation was adjusted to give a 100-300pA response at -70mV.

217   For p10 recordings, the current used was 0.3mA while for p20 recordings the current used was

218   0.1mA. Recordings were taken at different voltage steps, from -80mV to +40mV in the presence

219   of CNQX (20μM) and AP5 (50μM).

220

221   ***In vivo* extracellular recordings**

222   Surgery: Multisite extracellular recordings were performed in the PFC of P8–P10 (n=13) and P20–
223   P23 (n=14) C57/BL mice with both sexes. Mice were under urethane anesthesia (intraperitoneal
224   injection, 1 mg/g body weight; Sigma-Aldrich) before surgery. The bone over the mPFC (0.8 mm
225   anterior to bregma, 0.1–0.5 mm right to the midline) was carefully removed. One-shank
226   electrodes with 4 recording sites (0.4–0.8 MΩ impedance, 100 μm spacing, NeuroNexus) was
227   inserted into PFC at a depth of 1.9 mm from the skull surface. Electrodes were labelled with DiI
228   (1,1'-dioctadecyl-3,3,3',3'-tetramethyl indocarbocyanine; Invitrogen) to confirm their position
229   after histological assessment post-mortem. One silver wire was inserted into the cerebellum to
230   serve as ground and reference electrode.

231   Data Acquisition: A recovery period of 10 min following the insertion of electrodes before
232   acquisition of data was provided. Data acquired during the first 30 min of recording were used
233   for analysis to ensure similar state of anesthesia in all investigated pups. Extracellular signals
234   were bandpass filtered (0.1 Hz to 5 kHz) and digitized (32 kHz) with a multichannel extracellular
235   amplifier (Digital Lynx SX, Neuralynx) and the Cheetah acquisition software (Neuralynx).

236   Data Analysis: Data were imported and analyzed off-line using custom-written tools in MATLAB
237   software version 7.7 (MathWorks). Multiple unit activity (MUA) is detected when negative
238   deflections exceeding five times the SD of the bandpass filtered (500–5000 Hz) signals. Single
239   unit activity (USA)- was detected and clustered using klusta (Rossant et al., 2016) and manually
240   curated using phy (https://github.com/cortex-lab/phy). Data were imported and analyzed using
241   custom-written tools in the MATLAB. Burst activity was detected by using the method from
242   (Gorin, Tsitoura et al. 2016). First, for each unit, Poisson distribution, which assumed random
243   independent spiking, was defined. The single parameter λ of Poisson distribution is the average
244   firing rate of the unit. Second, the median interspike interval (ISI) value of the Poisson
245   distribution was derived. Third, we defined a burst activity as a sequence of ≥4 consecutive
246   spikes separated by intervals smaller than the median ISI. Last, the percentage of the burst
247   activity of a single unit is calculated by 100* (the number of the burst activity / the number of
248   the spikes). A unit was classified as "burst unit" if >50% of all spikes occurred in bursts.

249

250   **Immunohistochemistry**

251   Mice at the age of P10 and P20 were perfused with 4% paraformaldehyde, followed by fixation
252   with the same solution for 1h at 4∘C, followed by cryoprotection and preparation of 12 μm
253   cryostat sections as previously described[88]. Primary antibodies used were rat monoclonal anti-

8

254 GFP (Nacalai Tesque, Kyoto, Japan, 1:5000), rabbit polyclonal anti-GFP (1:500; Minotech

255 Biotechnology, Heraklion, Greece) and rabbit polyclonal anti-

256 parvalbumin (PV) (Swant, Bellinzona, Switzerland; 1:2000. Secondary antibodies used were goat

257 anti-rat-Alexa Fluor-488, goat anti-rabbit Alexa Fluor-488, and goat anti-rabbit-Alexa Fluor-555

258 (Molecular Probes, Eugene, OR, United States, 1:800). Images were obtained with a confocal

259 microscope (Leica TCS SP2, Leica, Nussloch, Germany). For each age group (P10, P20), 2-4 10μm-

260 thick sections from each mouse brain were selected, all including the mPFC and BC.

261

262 **RNA *In Situ* Hybridization**

263 Non-radioactive *in situ* hybridization experiments were performed on cryostat sections (12μm

264 thick, see immunochemistry) according to the protocol described (Schaeren-Wiemers and

265 Gerfin-Moser 1993). Riboprobe was prepared by *in vitro* transcription and was specific

266 Somatostatin (SST) (Liodis et al. 2007).

267

268 **Nissl Staining**

269 Cryostat sections (12μm thick, see immunochemistry) were incubated in 1:1 100%

270 ethanol:chloroform overnight at RT. Then, sections were rehydrated for 1 min in 100%, 95%

271 ethanol solutions and dH$_2$O at RT, followed by a 10-min incubation in 0.1% cresyl violet solution

272 at 50°C. Sections were then dehydrated with dH$_2$O, 95%, 100% ethanol and xylene for 5 min and

273 coverslipped with permount. Images from whole sections were obtained in 5× magnification of

274 a light microscope (Axioskop 2FS, Carl Zeiss AG, 268 Oberkochen, Germany) and merged using

275 Adobe Photoshop CC 2015, Adobe Systems, Inc.

276

277 **Analysis for Immunochemistry, *in situ* hybridization and Nissl staining**

278 Images taken from Nissl staining slices were analyzed with Matlab, using a custom-made

279 algorithm, which was double checked with hand-counting (Konstantoudaki et al. 2016;

280 Chalkiadaki et, 2019). Images from immunochemistry and in situ hybridization experiments,

281 were hand counted using ImageJ.

282

283 **Western blots**

284 Mice were decapitated following cervical dislocation, the brain was quickly removed, placed in

285 ice cold PBS (phosphate-buffered saline) and then positioned on a brain mould, where 1.5 mm

286 slices were taken containing the mPFC and BC. The slices were placed on dry ice, and the

287 prelimbic area of mPFC was dissected out and stored at -80°C. The BC was also isolated from the

288 corresponding slices and stored at -80°C. Frozen tissue blocks were lysed in a solution containing

289 (in mM) HEPES 50, NaCl 150, MgCl2 1.5, EGTA 5, Glycerol 1%, Triton-X100 1%, 1:1000 protease

290 inhibitors cocktail. Proteins ran on 8.5% bis-acrylamide gel and were transferred onto a

291 nitrocellulose membrane (Whatman GmbH, Dassel, Germany). The membrane was blocked,

292 incubated in rabbit polyclonal anti-K+/Cl-Cotransporter (KCC2) (Merck KGaA, Darmstadt,

293 Germany, 1:1000) or rabbit monoclonal anti-GAPDH (Cell Signaling Technology Europe BV,

294 Leiden, Netherlands, 1:1000), washed, incubated in secondary goat anti-rabbit IgG Horseradish

295 Peroxidase Conjugate antibody (Invitrogen, 1:5000), and digitally exposed using the Molecular

296 Imaging system ChemiDoc (BioRad Laboratories, Inc, California, U.S.A.). Analysis of KCC2 and

297 GAPDH expression was performed with ImageJ software, and the raw values of KCC2 from each

298 sample were normalized to their respective GAPDH values.

299

300 **Statistical analysis**

301 Statistical analyses were performed in Microsoft Office Excel 2007 and GraphPad Prism Software

302 7.0. Data are presented as mean ± standard error of mean (SEM). Normality distribution and

303 equality of variances of dataset were tested with the Kolmogorov-Smirnov test normality test.

304 The null hypothesis was rejected for a >5%. When four experimental groups (P10 mPFC, P20

305 mPFC, P10 BC and P20 BC) were assessed and two variables were taken into consideration (age

306 and brain area), data were analyzed with a two-way ANOVA with Fisher LSD, Sidak's or Tukey's

307 multiple comparisons (electrophysiological recordings and cell counting). When three groups

308 (P10 mPFC, P20 mPFC and P10 BC) data were analyzed with one-way ANOVA

309 (electrophysiological recordings). For the comparison of *in vivo* spiking activity between P10 and

310 P20, statistical analyses were performed with MATLAB. Significant differences were detected by

311 one-way ANOVA. Significance levels of $*p < 0.05$, $**p < 0.01$, $***p < 0.001$ or $****p < 0.0001$

312 were tested. For comparison of Western blot analysis, the significant effect of each

313 developmental age group from mPFC and BC was assessed using Student's t-test depending on

314 the experiment.

315

316 **Modeling**

317   We adapted the PFC microcircuit model we had developed previously (Konstantoudaki et al.,

318   2014) to fit our experimental data with regards to intrinsic properties of pyramidal neurons and

319   fast-spiking interneurons. We generated two model networks: a) a neonatal mPFC model

320   network and b) a juvenile mPFC model network. In the neonatal mPFC model network the

321   following adjustments were made: a) the pyramidal model neuron was adjusted to fit the passive

322   and active properties of the neurons recorded in this paper, primarily the neonatal pyramidal

323   model neuron exhibited increased input resistance and reduced spike amplitude, b) the fast-

324   spiking interneuron model neuron was adjusted to have reduced fast afterhyperpolarization, as

325   found in our experiments and c) the $GABA_AR$ receptor model had a reversal potential of -40mV.

326   In the juvenile mPFC model network, the following adjustments were made: a) the $GABA_AR$

327   receptor model had a reversal potential of -60mV. All other properties were maintained as in

328   the original model. The network was stimulated with spontaneous synaptic activation on

329   pyramidal model neurons with characteristics similar to the sEPSC and sIPSC properties we

330   recorded. Each condition was simulated in 10 different trials. In each trial, the location of

331   activated synapses varied.

332

333   **Data availability**

334   Data presented in the figures in this paper are available upon request.

335

336   **Results**

337   Mice belonging to two age groups were investigated: (i) neonatal mice included pups of

338   postnatal days (P) 9-11 and are defined as P10 while (ii) juvenile mice defined as P20 animals

339   included pups of P19-P21. Due to the high density of intra-cortical synapses in the superficial

340   cortical layers (DeFelipe and Fariñas 1992; Clancy et al. 2001) and their specific involvement in

341   neurodevelopmental disorders (Chini and Hanganu-Opatz, 2020; Bitzenhofer eta l., 2017) we

342   focused on the superficial layers of the mPFC and BC. From each mouse brain, both the mPFC

343   and the BC were studied. All analyses that had four groups (mPFC P10 and P20, BC P10 and P20)

344   were conducted using two-way ANOVA, with the two factors being the brain area (mPFC and

345   BC) and age (P10 and P20).

346

347   **Synaptic transmission adaptations in mPFC and BC across development**

348   To examine spontaneous synaptic transmission, we performed patch-clamp recordings from

349   layer II/III pyramidal neurons in mPFC and BC from P10 and P20 mice. We recorded spontaneous

350   inhibitory postsynaptic currents (sIPSCs, at +10mV) and spontaneous excitatory postsynaptic

351   currents (sEPSCs, at -60mV) and we measured the frequency, amplitude and decay time

352   constant.

353   In mPFC, the frequency of sIPSCs was significantly augmented at P20 compared to P10 (**Figure**

354   **1a,b**), while the sIPSC amplitude and decay-time constant did not significantly change over the

355   investigated time window (**Figure 1a,c,d**). Similarly, the sIPSC frequency and amplitude were

356   significantly increased, at P20 compared to P10, in BC (**Figure 1a,b,c**), while the decay-time

357   constant was not altered (**Figure 1a,d**). On a different note, the sIPSC in BC at P20 was

358   significantly increased compared to P10 in BC but also compared to P20 in mPFC.

359   The sEPSC frequency was significantly decreased at P20 compared to P10, in both areas (**Figure**

360   **1e,f**), while the amplitude and decay time constant were unaltered (**Figure 1g,h**). Upon

361   comparing the two brain areas, the sEPSC frequency and amplitude were found significantly

362   decreased in mPFC, compared to BC, at P10 (**Figure 1f**). At P20, the sEPSC frequency was similar

363   between the two cortical areas, while the amplitude remained significantly smaller in mPFC

364   compared to BC in both ages (**Figure 1g**). The decay time constant was not different between

365   areas at both ages (**Figure 1h**).

366   We further investigated the changes in sIPSC and sEPSC frequency changes in the mPFC, in

367   particular, in the presence of AMPA and NMDA receptor antagonists, CNQX and AP5, respectively

368   and a GABA$_A$ receptor antagonist, bicuculine. The sIPSC frequency remained increased at P20,

369   compared to P10, CNQX and AP5 (**Figure 2a,c**). On the other hand, bicuculine blocked the sIPSCs

370   both in P10 and P20 mPFC (**Figure 2 b, c**). Application of CNQX eliminated the sEPSCs in mPFC

371   slices at P20 and significantly reduced, but did not eliminate sEPSCs, in mPFC slices at P10 (**Figure**

372   **2e,g**). Application of bicuculine (10uM) did not affect the sEPSC frequency in mPFC slices at P20

373   but significantly reduced sEPSC frequency at mPFC P10 (**Figure 2f,g**). These results suggest that

374   depolarizing GABA$_A$R currents could contribute to the increased sEPSC frequency observed in

375   layer II/III mPFC pyramidal neurons at P10.

376

377   **GABA is depolarizing in the neonatal mPFC but not BC**

378   Our data so far suggests that GABA$_A$R function is still depolarizing at P10 in the mPFC. To further

379   investigate this, we performed evoked IPSCs (eIPSCs) at P10 and P20 mPFC in the presence of

380   CNQX and AP5 at different voltage steps. A line curve was fit across the eIPSC currents recorded

381   from -60mV to +10mV, because there was a linear V-I relationship at this range. From the graphs,

382   it is evident that reversal potential at P10 is more positive than -30mV, while the reversal

383   potential at P20 is around -45mV (**Figure 3a,b**).

384   We further investigated the GABA$_A$R activity by isolating a GABA$_A$R response in fEPSP recordings

385   by using CNQX and AP5. The addition of diazepam (2μM) (a GABA$_A$R agonist) increased the fEPSP

386   amplitude in mPFC at P10, but not at P20 (**Figure 4a-b**). In BC, there was no effect of diazepam,

387   either at P10 or P20 (**Supplemental Figure 1**). The switch in the GABA$_A$R function from

388   depolarizing to hyperpolarizing occurs due to the increased expression of the K^+-Cl^- co-

389   transporter 2 (KCC2) (Rivera et al. 1999). To determine whether modulating chloride

390   transporters could alter the diazepam-induced enhancement of the fEPSP at P10 mPFC, we

391   recorded the fEPSP in the presence of bumetanide (10uM), which blocks the NKCC1 transporter,

392   and tested the effect of diazepam. We find that in the presence of bumetanide, diazepam did

393   not result in an increase of the fEPSP (**Figure 4c-d**). In addition, we measured KCC2 protein levels

394   and demonstrated that they were significantly increased at P20 compared to P10 in the mPFC

395   but not in the BC (**Figure 4e-g**). The above results collectively suggest that the GABA$_A$R function

396   is depolarizing in the mPFC at P10.

397

398   **Passive and active membrane properties of MGE-derived interneurons are altered in the mPFC**

399   **across development**

400   To investigate whether the change in GABA$_A$R function in mPFC is also associated with changes

401   in interneuron properties, we performed current-clamp recordings from layer II/III mPFC and BC

402   of Lhx6$^+$ interneurons. For this reason, Lhx6-cre;ROSA26fl-STOP-fl-YFP mice were used in which

403   Lhx6$^+$ interneurons express YFP. Lhx6 is expressed by all post-mitotic and mature MGE-derived

404   interneurons (Liodis et al. 2007), therefore, YFP is expressed in MGE-derived interneurons, which

405   include interneurons that express parvalbumin (PV$^+$) and somatostatin (SST$^+$).

406   Upon analysis of the passive properties, we found a significant increase in the input resistance

407   and membrane time constant, as well as a significant decrease in the membrane capacitance in

408   the mPFC at P10 compared to P20 (**Figure 5**). In addition, the input resistance and the membrane

409   time constant were higher at P10 mPFC, compared to BC (P10 and P20). There was no difference

410   in the resting membrane potential (RMP) between ages and brain areas (**Figure 5,**

411   **Supplementary Table 1**).

412   Regarding the active properties, there was no significant difference between ages and brain

413   areas in the AP amplitude, AP threshold and rheobase, fAHP time (duration) (**Figure 5a, d, e, g;**

414   **Supplementary Table 1**). The AP rate of rise (dv/dt) was significantly increased while the AP

415   duration (half-width) was significantly reduced at P20 compared to P10 in both the mPFC and

416   BC (**Figure 6b,c, Supplementary Table 1**). In addition, the fAHP amplitude was significantly lower

417   in the mPFC (**Figure 6f, Supplementary Table 1**), compared to BC. The increased rate of rise and

418   the decreased AP duration are possibly linked with the up-regulation of voltage-dependent

419   sodium channels during development (Huguenard et al. 1988), and in combination with the

420   reduced fAHP amplitude suggest that the mPFC MGE-interneurons at P10 are still quite

421   immature, when compared to adult PV[+]/SST[+] interneurons in mPFC (Yang et al. 2013; Pan et al.

422   2017).

423   Overall, these data indicate that some intrinsic properties of interneurons in mPFC change with

424   age (from P10 to P20), reaching values that closer resemble adult MGE-derived interneurons

425   (Yang et al. 2013; Pan et al. 2017). The increased sIPSC frequency of mPFC pyramidal neurons

426   observed at P20, compared to P10 could partly be explained by these altered properties of

427   presynaptic interneurons.

428

429   **Decreased PV interneurons in mPFC compared to BC**

430   An additional explanation for the adaptations in inhibitory transmission could come from

431   alterations in interneuron cell densities. To test this, we quantified the number of interneurons

432   per area in cryosections at P10 and P20 mPFC and BC coronal brain slices of Lhx6[+]-expressing

433   mice. The YFP[+] positive cells per area (i.e. Lhx6[+] cell density) in mPFC and BC was similar between

434   ages, but was significantly lower in the mPFC, compared to BC (**Figure 7a**). But we found no

435   contribution of cell death in the mPFC interneuron population, as the percentage of cell death

436   in Lhx6[+] neurons is very low in both P10 mPFC and BC (**Supplementary Figure 2**).

437   The transcription factor Lhx6 is required for the specification and maintenance of main MGE-

438   derived interneurons, PV and SST-positive interneuron subtypes, at postnatal ages (Liodis et al.

439   2007). The neuropeptide SST (both mRNA and protein) is progressively expressed from

440   embryonic to postnatal levels (Bendotti et al. 1990; Forloni et al. 1990). We found that the SST

441   mRNA levels were similar between areas and ages (**Figure 7b**). On the other hand, the

442   emergence of PV immunoreactivity in the mouse cortex shows a delayed development, starting

443   from early postnatal period to adult, with marked area-specific differences(Del Rio et al. 1992).

14

444   We found that PV was only immunoreactive in BC, and not in mPFC, at P10 (**Figure 7c and**

445   **Supplementary Figure 3**). At P20, PV was immunoreactive in both mPFC and BC, but PV$^+$ cell

446   density was significantly lower in the mPFC, compared to BC (**Figure 7c**).

447   We also counted the total cell density of mPFC and BC from neonatal and juvenile mice

448   (**Supplementary Figure 4a**) using Nissl staining. In the mPFC, the cell density significantly

449   decreased at P20 compared to P10 (**Supplementary Figure 4b**). On the contrary, in BC, the total

450   cell density significantly increased at P20 compared to P10 (**Supplementary Figure 4b**). When

451   the two brain areas were compared, no difference was found at P10, while the mPFC cell density

452   was significantly lower compared to BC at P20 (**Supplementary Figure 4b**).

453   We further examined whether the alterations in total cell density are derived from alterations

454   in cell density of interneurons by measuring the Lhx6$^+$ neurons over the Nissl-positive cells. No

455   differences were detected between areas and ages (**Supplementary Figure 4c).** These results

456   suggest that the changes in total cell density in mPFC and BC respectively are probably due to

457   changes in other neuronal or glial populations.

458

459   **No significant changes in pyramidal neuron excitability**

460   To determine whether the reduced sEPSC frequency can be explained by changes in pyramidal

461   neuron excitability, we investigated their intrinsic properties. The passive and active properties

462   of these neurons were measured using current-clamp recordings from layer II/III mPFC and BC

463   pyramidal neurons. With regards to passive properties, no significant differences were observed

464   in the RMP, the input resistance and the membrane time constant between brain regions and

465   ages (**Supplementary Figure 5, Supplementary Table 1**). Only the membrane capacitance was

466   significantly increased at P20 compared to P10 (**Supplementary Figure 5d, Supplementary Table**

467   **1**), in both brain areas. In addition, the number of spikes generated with increasing current

468   stimulation was not significantly different between ages and regions (**Supplementary Figure 6**).

469   In terms of active properties, the AP amplitude and rate of rise were increased at P20 compared

470   to P10 mPFC, while the AP half-width, rheobase and threshold were not significantly different

471   (**Figure 8, Supplementary Table 1**). The AP amplitude was also significantly increased at P20,

472   compared to P10 in BC, while the other properties did not change (**Figure 8, Supplementary**

473   **Table 1**). Comparing the two regions at the two ages, we found no significant differences of AP

474   properties of pyramidal neurons (**Figure 8, Supplementary Table 1**). The developmental increase

475   of AP amplitude and rate of rise in the mPFC could be due to the on-going maturation of sodium

476   channels in pyramidal neurons. However, these changes could not account for the reduced

477   sEPSCs in the neonatal, compared to juvenile, mPFC and BC.

478

479   **Effects of mPFC changes in intrinsic and synaptic properties on PFC network activity**

480   In an effort to understand the circuit effects of the aforementioned differences in intrinsic and

481   synaptic properties between p10 and P20 mPFC, we adapted an already validated PFC network

482   model (Konstantoudaki et al., 2014) to our current data to generate a neonatal (P10) mPFC

483   model network and juvenile (P20) mPFC model network. Both model networks were stimulated

484   with spontaneous excitatory and inhibitory inputs based on our results for sEPSC and sIPSC

485   frequency at P10 and P20 (**Figure 1 and Supplementary Table 1**). Our simulation results predict

486   that the intrinsic and synaptic changes from P10 to P20 in mPFC result in enhanced mPFC

487   network activity at P20, compared to P10 (**Figure 9a,e**), as indicated by single-cell activity (**Figure**

488   **9a,b**) and the filtered signal (**Figure 9c,d**). Furthermore, we investigated which adaptations have

489   a significant contribution to the network activity properties observed in each model network.

490   Therefore, we generated neonatal model networks in which the pyramidal model neuron used

491   had P20 properties (N2 network), the fast-spiking interneuron model used had P20 properties

492   (N3 network) and the GABA$_A$R reversal potential was that of P20 (N4 network). We identify that

493   in all the above networks, the resulting neuronal activity generated was significantly reduced

494   compared to the control P10 network (N1) (**Figure 9f**). Similarly, we generated juvenile model

495   networks in which the pyramidal model neuron used had P10 properties (J2 network), the fast-

496   spiking interneuron model used had P10 properties (J3 network) and the GABA$_A$R reversal

497   potential was that of P10 (J4 network). We find that the resulting neuronal activity generated

498   was significantly increased compared to the control P20 network (J1) (**Figure 9g**).

499

500   **Increased firing activity *in vivo* in the mPFC between the second and third postnatal weeks**

501   To determine whether our modeling prediction on network activity changes can be validated *in*

502   *vivo*, multisite recordings of the LFP and multi-unit activity (MUA) were performed in layers II/III

503   of mPFC at P8-10 and P20-23. A significant increase of MUA was identified at P22 compared to

504   P9 mice, indicating a developmental increased spiking activity in layers II/III of mPFC on the third

505   compared to the second postnatal week (**Figure 10**). Similarly, the spiking activity in the BC

506   augmented with age (**Supplementary Figure 7**). To characterize the firing dynamics along

507   development, we used MUA for clustering single-unit activity. We detected bursts of spikes using

508 the previously developed method (Gorin et al. 2016). The burst occurrence in the mPFC

509 increased with age (33.62±1.91 %, 161 single units at neonatal age vs. 50.12±4.91 %, 150 single

510 units at juvenile age; p<0.0001, One-way ANOVA, $F_{(1, 309)}$=272.26). Correspondingly, the number

511 of units organized in bursts increased with age, as well, from 21 out of 161 single units at

512 neonatal age to 104 out of 150 single units at juvenile age (**Figure 10d**). Moreover, we analyzed

513 the mPFC and BC units in their amplitude, dv/dt and half-width and detected, similarly to the in

514 vitro conditions, a significant increase in the AP amplitude and rate of rise but no difference in

515 the half-width (**Supplementary Figure 8**). These results provide further evidence that the

516 decreased excitatory synaptic activity of mPFC cannot be attributed to increased spiking activity

517 of mPFC neurons at P10.

518

519 **Discussion**

520 Our study has identified significant developmental events in the mPFC and the BC between the

521 second and third postnatal weeks. Specifically, we have shown that spontaneous inhibitory

522 transmission, measured as sIPSCs, is increased in mPFC from P10 to P20. Moreover, our data

523 support a depolarizing action of $GABA_AR$ in the second postnatal week, in the mPFC, as indicated

524 by the presence of non-AMPAR-mediated sEPSCs, depolarizing reversal potential of evoked

525 $GABA_AR$ responses, increased basal fEPSPs following $GABA_AR$ activation, which is blocked by

526 concurrent bumetanide application, and decreased protein levels of KCC2. In parallel,

527 differences the intrinsic properties of GABAergic interneurons of mice in the juvenile period

528 resemble are more mature, compared to the neonatal period in mPFC. The above

529 developmental adaptations, along with increased AP amplitude and AP rate-of-rise in pyramidal

530 cells age result in augmented network activity in the juvenile mPFC, compared to the neonatal

531 mPFC.

532

533 **Depolarizing action of GABA in the immature cortex**

534 GABA plays a crucial role in inhibiting adult neurons, acting primarily via the chloride-permeable

535 $GABA_AR$ and resulting in hyperpolarization of the membrane potential (Kaila and Voipio 1987).

536 However, GABA action leads to depolarization of immature neurons (i.e. during the first

537 postnatal week in mice), due to an initially higher intracellular chloride concentration $[Cl^-]_{in}$ (Ben-

538 Ari 2001; Ben-Ari et al. 2007; Ben-Ari 2012). The developmental switch of GABA action from

539 depolarizing to hyperpolarizing results from changes in cation-chloride co-transporter

17

540   expression: NKCC1, a cation-Cl$^-$ importer, is highly expressed in neuronal precursor cells during

541   early brain development (Plotkin et al. 1997; Yamada et al. 2004), while the expression of the

542   K$^+$-Cl$^-$ cotransporter 2 (KCC2), a cation-Cl$^-$ exporter, increases after the first postnatal week (Ben-

543   Ari 2001; Ben-Ari et al. 2007; Ben-Ari 2012). This increased KCC2 transporter expression might

544   provide a central mechanism for the depolarization to hyperpolarization switch of GABAergic

545   transmission via progressive reduction of $[Cl^-]_{in}$ (Lu et al. 1999; Rivera et al. 1999; Ganguly et al.

546   2001; Ben-Ari 2002; Dzhala et al. 2005; Fiumelli et al. 2005).

547   The GABA$_A$R switch from depolarizing to hyperpolarizing occurs at P7 in the hippocampus,

548   cortex, amygdala (Ben-Ari et al. 1989; Luhmann and Prince 1991; LoTurco et al. 1995; Owens et

549   al. 1996; Martina et al. 2001; Gulledge and Stuart 2003; Ben-Ari et al. 2007). The most

550   developmentally delayed switch in the GABAergic polarity has identified in the mPFC. In Rinetti-

551   Viargas et al., 2017, they showed that the GABA$_A$ signaling matures around birth at dendrites

552   and after preadolescent period (~P20) at axon initial segment of prefrontal pyramidal neuros.

553   They showed the changes in local chloride transporters function using gramicidin-based

554   perforated patch recordings and applied GABA via an iontophoretic pipette. We reinforce the

555   GABA$_A$ signaling change using evoked IPSC recordings in the soma if prefrontal pyramidal

556   neurons.

557   Our study suggests that this switch is delayed in the mPFC compared to primary somatosensory

558   cortex and it takes place between P10 and P20. Specifically, we show that increased GABA$_A$R

559   activity leads to enhanced fEPSPs in neonatal mPFC (P10), suggesting that the GABA$_A$R function

560   is depolarizing in the mPFC at P10. This enhancement is prevented in the presence of the NKCC1

561   blocker, bumetanide. Furthermore, diazepam increases the number of spontaneous activity

562   events in the brain slice, which is also prevented in the presence of bumetanide. This hypothesis

563   is further supported by decreased levels of KCC2 transporter in the neonatal mPFC and it is

564   conceded the age- dependent differences in membrane NKCC1 and KCC2 protein level and

565   phosphorylation (Rinetti-Viargas et al., 2017) Our results could have implications for

566   understanding the protracted maturation of mPFC compared to other cortical areas, which may

567   depend on a combination of a delayed switch from depolarizing-to-hyperpolarizing function of

568   GABA$_A$R and maturation of interneurons.

569

570   **Interneurons and mPFC development**

571 Recordings of Lhx6[+]- interneurons indicate that both passive and active properties are regulated

572 by age and reach values that better resemble adult MGE-derived interneurons. Specifically, we

573 have found that the input resistance and AP width decrease while the AP rate of rise increases

574 in the mPFC at P20 compared to P10. In part, similar findings have been identified for PV[+] cells

575 in the hippocampus (Doischer et al. 2008; Miyamae et al. 2017) and SST[+] cells in the anterior

576 cingulate cortex (Pan et al. 2017). On the other hand, the AHP amplitude is still quite immature

577 in the mPFC at P20, compared to PV[+], SST[+] interneurons in primary sensory areas or the

578 hippocampus and compared to adult mPFC (Doischer et al. 2008; Yang et al. 2013; Pan et al.

579 2017). Therefore, it is likely that the physiological properties of PV+ and SST+ interneurons in

580 the mPFC continue to change past the third postnatal week.

581 Our knowledge on the neonatal physiology of mPFC GABAergic interneurons is very limited. It

582 has been shown that PV expression is lowest in juveniles and increases during adolescence to

583 levels similar to those observed in adulthood (Caballero et al. 2014). Furthermore, PV expression

584 is not evident in the neonatal period and emerges during the juvenile period in the mPFC (del

585 Rio et al. 1994; de Lecea et al. 1995; Zheng et al. 2011; Spampanato and Sullivan 2016). Our

586 results agree with these findings, as PV expression was detected in very low amounts during the

587 juvenile period in the mPFC.

588 In addition, our study has identified decreased excitatory and increased inhibitory synaptic

589 function between the second and third postnatal weeks. We show that the frequency of sIPSCs

590 in layer II/III pyramidal cells of mPFC increases from neonatal to juvenile period, consistent with

591 the developmental changes of IPSCs in layer III pyramidal neurons of monkey PFC (González-

592 Burgos et al. 2015) and mouse mPFC (Kroon et al. 2019).

593

594 **Pyramidal neurons and network activity**

595 It has been suggested that spontaneous network activity changes from local, highly synchronized

596 to more diffuse from the second to the third postnatal weeks, in the primary sensory cortices

597 (Golshani et al. 2009; Frye and MacLean 2016). Oscillatory activity in the mPFC first emerges at

598 P15 (Bitzenhofer et al. 2019). In this study, we have found increased spiking activity in the mPFC

599 during the third, compared to the second postnatal week. This occurred despite the decreased

600 excitatory and increased inhibitory synaptic function, but could be explained partly by the

601 developmental increase of AP amplitude and rate of rise in the mPFC layer II/III pyramidal

602 neurons, which could be due to the on-going maturation of sodium channels in pyramidal
603 neurons.

604 Studies in developing mPFC pyramidal neurons have proposed that there is a unique sensitive
605 time window for synaptic maturation of these neurons from individual cortical layers. During rat
606 mPFC layer V development, the intrinsic properties, synaptic inputs and morphology of
607 pyramidal neurons develop together during early postnatal life. While the greatest changes were
608 reported during the first ten days after birth, the adult-like properties emerged after the end of
609 the third week (P21) (Zhang et al. 2011). This study confirms that the second postnatal week is
610 a period of rapid growth, similar to that in other neocortical regions by combining functional and
611 structural measurements of developing pyramidal neurons in mouse mPFC (Zhu 2000; Romand
612 et al. 2011).

613 **Developmental PFC malformation leads to cognitive disorders in adulthood**

614 The neonatal functional maturation of GABAergic circuits and E/I (excitation to inhibition)
615 balance are critical for PFC-dependent behaviours and plasticity in the adult while their
616 malfunction leads to many psychiatric disorders (Benes 1991; Kilb 2012; Ferguson and Gao
617 2018). From the prenatal period to late adolescence, the PFC network is highly vulnerable to
618 genetic and environmental factors (Andersen 2003), since the mPFC is one of the latest cortical
619 regions to develop (Huttenlocher 1990). While many studies have focused on understanding
620 several developmental processes during adolescence (Caballero et al. 2016), our knowledge
621 regarding the ongoing cellular and network developmental processes during the perinatal period
622 is notably limited, despite significant evidence showing that environmental manipulations
623 during this period manifest as complex psychiatric and neurologic disorders in adulthood
624 (Weinberger 1986).

625 The delayed developmental shift of GABA action in various mouse models mimicking human
626 brain disorders have been investigated, including the maternal immune activation model
627 (Corradini et al. 2018; Fernandez et al. 2018), the Scn1a and Scn1b mouse models of Dravet
628 syndrome (Yuan et al., 2019), the 22q11.2 deletion syndrome (Amin et al. 2017) and the Fmr1
629 deficient model of fragile X syndrome (He et al. 2018). In the latter study, early postnatal
630 correction of GABA depolarization (bumetanide-treated) led to sufficient normalization of the
631 mature BC network (He et al. 2018). The impaired KCC2 has been proposed as a potential
632 therapeutic target of epilepsies by many studies in animal models and human patients (Moore
633 et al. 2017).

20

634 Our study focuses in understanding the early developmental cellular and physiological
635 mechanisms of mPFC circuits, before adolescence, and proposes that the neonatal mPFC
636 compared to BC exhibits a delayed switch from depolarization to hyperpolarization function of
637 GABA$_A$R. Our results raise the possibility that the delayed maturation of mPFC compared to other
638 cortical areas depends on a combination of a delayed switch from depolarization to
639 hyperpolarization function of the GABA$_A$R and delayed maturation of interneurons.

Figure 1
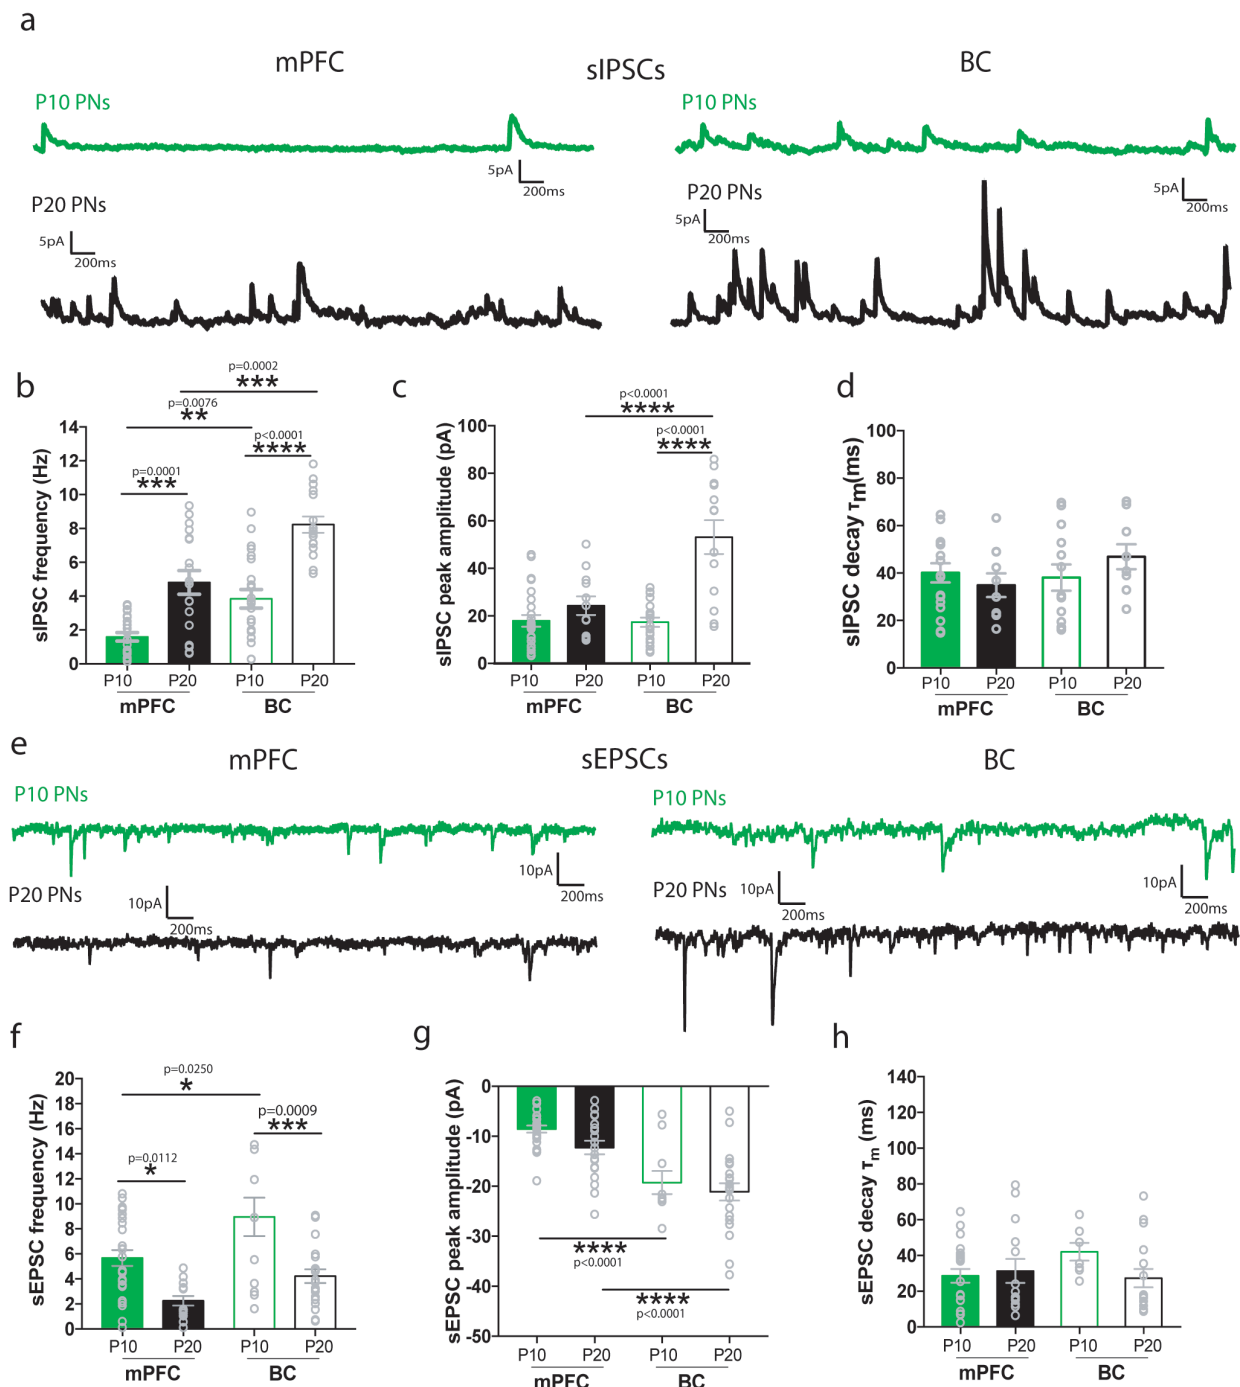

Figure 1. Properties of sIPSCs and sEPSCs at P10 and P20 of layer II/III mPFC and BC pyramidal neurons

(a) Representative traces of spontaneous inhibitory postsynaptic currents (sIPSCs) from layer II/III mPFC (left) and BC (right) pyramidal neurons at P10 (green) and P20 (black).

(b) Bar graph showing the sIPSC frequency (Hz) at P10 and P20 mPFC and BC pyramidal neurons. Two-way ANOVA analyses showed a significant effect of age ($F_{(1,26)}$=19.286, p<0.001) and brain

901   area ($F_{(1,26)}$=12.554, p=0.002) and a trend towards significance of age*brain interaction

902   ($F_{(1,26)}$=3.826, p=0.063).

903   **(c)** Bar graph showing the sIPSC peak amplitude at P10 and P20 of mPFC and BC pyramidal

904   neurons. Two-way ANOVA analyses showed a trend towards significance in the brain area factor

905   ($F_{(1,26)}$=3.420, p=0.077) and no effect of age ($F_{(1,26)}$=1.981 p=0.177) or area*age interaction

906   ($F_{(1,26)}$=0.050, p=0.826).

907   **(d)** Bar graph showing the sIPSC decay time constant (τm) at P10 to P20 of mPFC and BC

908   pyramidal neurons. Two-way ANOVA analyses did not show any significant effect of age

909   ($F_{(1,26)}$=1.129, p=0.299), brain area ($F_{(1, 26)}$=0.211, p=0.651) or area*age interaction ($F_{(1, 26)}$=1.052,

910   p=0.316) was found.

911   **(e)** Representative traces of spontaneous excitatory postsynaptic currents (sEPSCs) from layer

912   II/III mPFC (left) and BC (right) pyramidal neurons at P10 (green) and P20 (black).

913   **(f)** Bar graph showing the sEPSC frequency at P10 to P20 of mPFC and BC pyramidal neurons.

914   Two-way ANOVA analyses showed a significant effect of age ($F_{(1,25)}$=5.273, p=0.032) and brain

915   area ($F_{(1,25)}$=7.388, p=0.013), but not a significant interaction age*brain area ($F_{(1,25)}$=0.591,

916   p=0.450)

917   **(g)** Bar graph showing the sEPSCs peak amplitude at P10 to P20 of mPFC and BC pyramidal

918   neurons. Two-way ANOVA analyses did not reveal significant effect of brain area ($F_{(1,25)}$=0.853,

919   p=0.366), age ($F_{(1,25)}$=0.144, p=0.708) or interaction ($F_{(1,25)}$=0.712, p=0.408).

920   **(h)** Bar graph showing the sEPSCs decay time constant (τm) at P10 to P20 of mPFC and BC

921   pyramidal neurons. Two-way ANOVA analyses showed no significant effect of age ($F_{(1,25)}$=0.557,

922   p=0.463), brain area ($F_{(1,25)}$=0.720, p=0.405) or interaction ($F_{(1,25)}$=1.128, p=0.300).

923   *n=9-13 cells from 5-9 mice/age group.

924

Figure 2
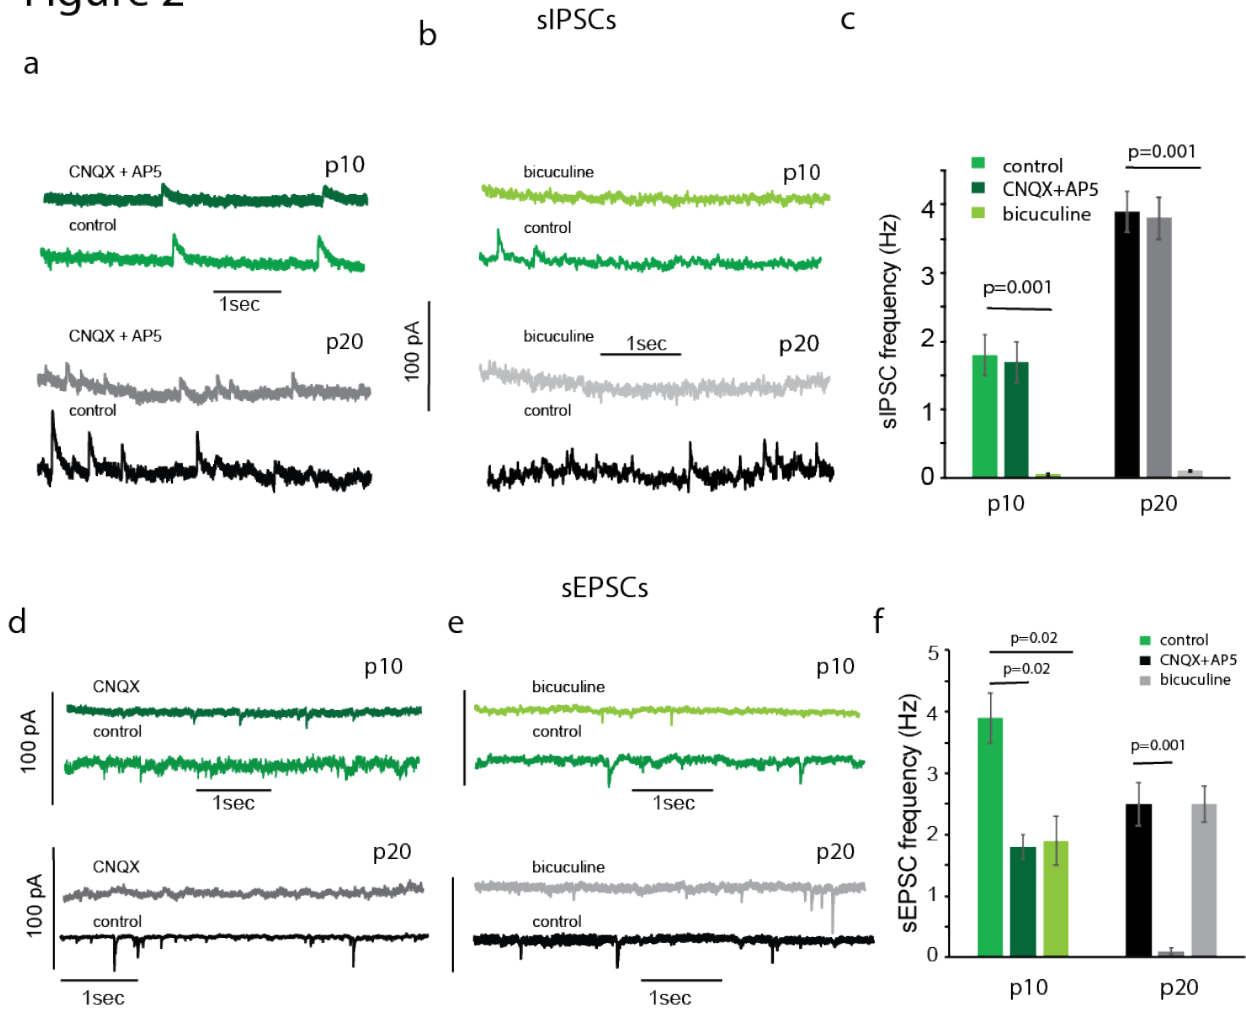

Figure 2- sIPSCs and sEPSCs frequency at P10 and P20 of layer II/III mPFC and BC pyramidal neurons

(a) Representative traces showing that CNQX+AP5 did not alter the sIPSC frequency either at P10 or P20 mPFC (recorded at +10mV).

(b) Representative traces showing that bicuculine blocks sIPSCs either at P10 or P20 mPFC (recorded at +10mV).

(c) Graphs showing that bicuculine blocks the sIPSCs in P10 and P20 mPFC (t-test, p=0.001), while CNQX+AP5 does not have an effect (t-test, p=0.5).

(d) Representative traces showing that CNQX reduces sEPSC frequency at p10 and blocks sEPSCs at P20 mPFC (recorded at -70mV).

(e) Representative traces showing that bicuculine reduces sEPSC frequency at p10 and does not affect sEPSCs at P20 mPFC (recorded at -70mV).

939 **(f)** Graphs showing that at P10 mPFC both CNQX+AP5 and bicuculine reduces the sEPSC

940 frequency in P10 mPFC (t-test, p=0.03 for both drugs), while in P20 mPFC only CNQX+AP5 blocks

941 sEPSCs.

Figure 3
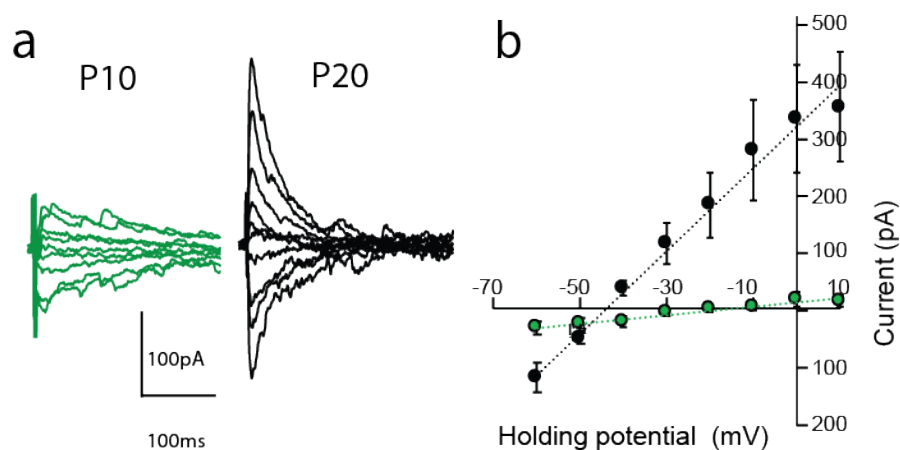

Figure 3 – The reversal potential for evoked IPSCs is depolarized at p10 mPFC compared to p20

(a) Representative traces of evoked IPSCs at p10 and p20 mPFC

(b) Graph showing the average of eIPSCs at different holding potentials.
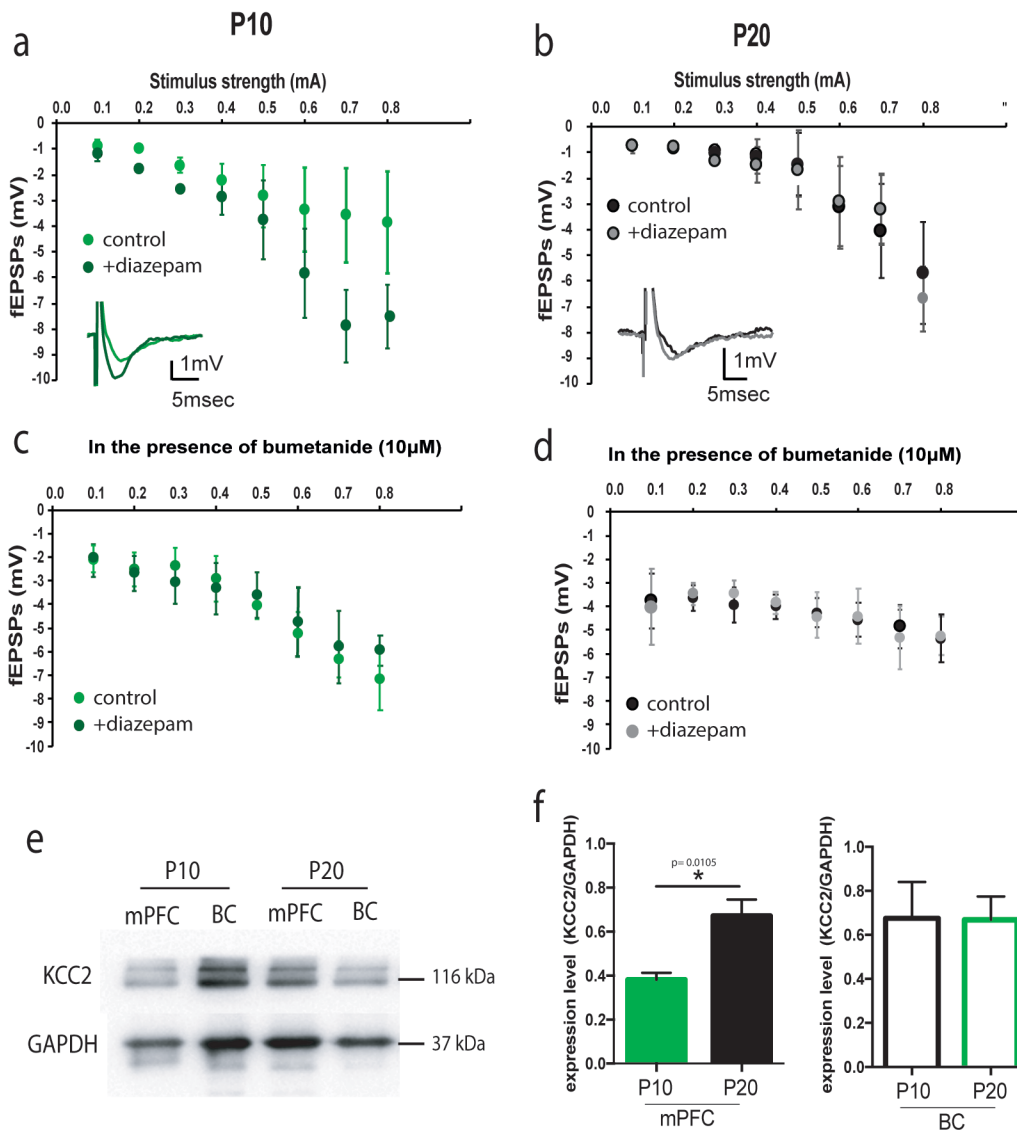

Figure 4

Figure 4. Changes in the chloride transporters mediate the depolarizing action of GABA$_A$R at p10 mPFC

fEPSPs were recorded were recorded in layer II/III mPFC in response to current pulses of increasing stimulus strength of layer II/III, during two experimental treatments, before and after application of 2µM diazepam (GABA$_A$R agonist) at P10 and P20.

(a) Representative traces (left) and graph (right) showing the fEPSPs amplitude before (green) and after (dark green) diazepam bath application (in the presence of CNQX and AP5), in mPFC at P10. Two-way repeated measures ANOVA analyses of evoked fEPSPs revealed significant effect of stimulus strength ($F_{(1,7)}$ = 20.64, p=0.004) and experimental treatments ($F_{(1,7)}$ = 5.025, p=0.036) (n=2 brain slices from 3-4 mice).

983   **(b)** Graph (right) and representative traces (left) showing that diazepam bath application does

984   not have any effect on the fEPSP amplitude in mPFC at P20 (in the presence of CNQX and AP5).

985   Two-way repeated measures ANOVA analyses of evoked fEPSPs revealed a significant effect of

986   stimulus strength ($F_{(1,7)}$ = 10.36, p<0.0001) but not experimental treatment ($F_{(1,7)}$=0.03,

987   p=0.9382), (n=2 brain slices from 3-4 mice).

988   **(c)** Graph showing that the effect of diazepam on fEPSP is occluded in the presence of

989   bumetanide (plus CNQX and AP5) at P10. Two-way repeated measures ANOVA analyses of

990   evoked fEPSPs did not reveal a significant effect of experimental treatment ($F_{(1,7)}$=0.08, p=0.752),

991   (n=2 brain slices from 3-4 mice).

992   **(d)** Graph showing the effect of diazepam on fEPSP in the presence of bumetanide (plus CNQX

993   and AP5) at P20. Two-way repeated measures ANOVA analyses of evoked fEPSPs did not reveal

994   a significant effect of experimental treatment ($F_{(1,7)}$=0.06, p=0.831), (n=2 brain slices from 3-4

995   mice).

996   **(e)** Representative blots showing changes of the K-Cl co-transporter (KCC2) levels, relative to

997   GAPDH at P10 and P20 in mPFC and BC.

998   (f) Graph showing the normalized protein level (KCC2/GAPDH) in mPFC at P10 and P20. The KCC2

999   protein levels was significantly increased at P20 compared to P10 in mPFC (two-tailed t-test, p=

1000   0.01) but not in BC (two-tailed t-test, p= 0.97) (n=3-4 mice).

Figure 5

1016

Figure 5. Poor development of active membrane properties of Lhx6+ interneurons in mPFC.

(a) Bar graph showing the action potential (AP) amplitude of interneurons at P10 and P20 in mPFC and BC. Two-way ANOVA analyses did not show any significant effect of age ($F_{(1,22)}=2.46$, p=0.13) or brain area ($F_{(1, 22)}=2.13$, p=0.15) was found., (n=6-9 cells from 5-6 mice/age group).

(b) Bar graph showing the AP rate of rise (dv/dt) of interneurons at P10 and P20 in mPFC and at P10 in BC. Two-way ANOVA analyses showed a significant effect between ages ($F_{(1,20)}=58.96$, p<0.0001) but not brain area ($F_{(1,20)}=0.16$ p=0.69). Post-hoc analysis showed that the AP rate of rise significantly increased at P20 compared to P10 in mPFC (Tukey's test, p=0.0034) and at P20 compared to P10 in BC (Tukey's test, p<0.001), (n=6-9 cells from 5-6 mice/age group).

(c) Bar graph showing the AP duration (half-width) of interneurons at P10 and P20 in mPFC and BC. Two-way ANOVA analyses showed a significant effect between ages ($F_{(1,21)}=39.16$, p<0.0001) but not brain area ($F_{(1,21)}=0.16$ p=0.73). Post-hoc analysis showed that the AP duration significantly decreased at P20 compared to P10 in mPFC (Tukey's test, p= 0.0093) and at P20 compared to P10 in BC (Tukey's test, p=0.0002), (n=6-9 cells from 5-6 mice/age group).

(d) Bar graph showing the AP rheobase of interneurons at P10 and P20 in mPFC and BC. Two-way ANOVA analyses did not show any significant effect of age ($F_{(1,20)}=1.60$, p=0.22) or brain area ($F_{(1, 20)}=0.40$, p=0.53) was found.

1034 **(e)** Bar graph showing the AP threshold of interneurons at P10 and P20 in mPFC and BC. . Two-

1035 way ANOVA analyses showed significant effect of age ($F_{(1,22)}$=5.048, p=0.035) and brain area ($F_{(1,22)}$

1036 $_{22)}$=8.00, p=0.009) was found. Post-hoc analysis showed that the AP threshold was not

1037 significantly different at P20 compared to P10 in mPFC (Tukey's test, p=0.1673) and in BC

1038 (Tukey's test, p=0.72009) or at P10 in mPFC compared to P10 in BC (Tukey's test, p=0.067) and

1039 at P20 in mPFC compared to P20 in BC (Tukey's test, p=0.72).

1040 **(f)** Bar graph showing the AHP (afterhypolarization) amplitude of interneurons at P10 and P20

1041 in mPFC and BC. Two-way ANOVA analyses showed significant effect of age ($F_{(1,18)}$=7.35,

1042 p=0.0143) and brain area ($F_{(1, 18)}$=63.72, p<0.0001) was found. Post-hoc analysis showed that the

1043 AHP amplitude was not significantly different at P20 compared to P10 in mPFC (Tukey's test,

1044 p=0.7187) and was significantly decreased in mPFC compered to BC, at P10 (Tukey's test, p=

1045 0.0005) and in mPFC compered to BC at P20 (Tukey's test, p<0.00001), (n=6-9 cells from 5-6

1046 mice/age group).

1047 **(g)** Bar graph showing the AHP time of interneurons at P10 and P20 in mPFC and BC. Two-way

1048 ANOVA analyses did not show any significant effect of age ($F_{(1,19)}$=0.009, p=0.92) or brain area

1049 ($F_{(1, 19)}$=1.074, p=0.31) was found.

1050 **(h)** Representative traces of APs of layer II/III Lhx6+ interneurons in mPFC (left) and BC (right)

1051 at P10 (green) and P20 (black).

1052

Figure 6
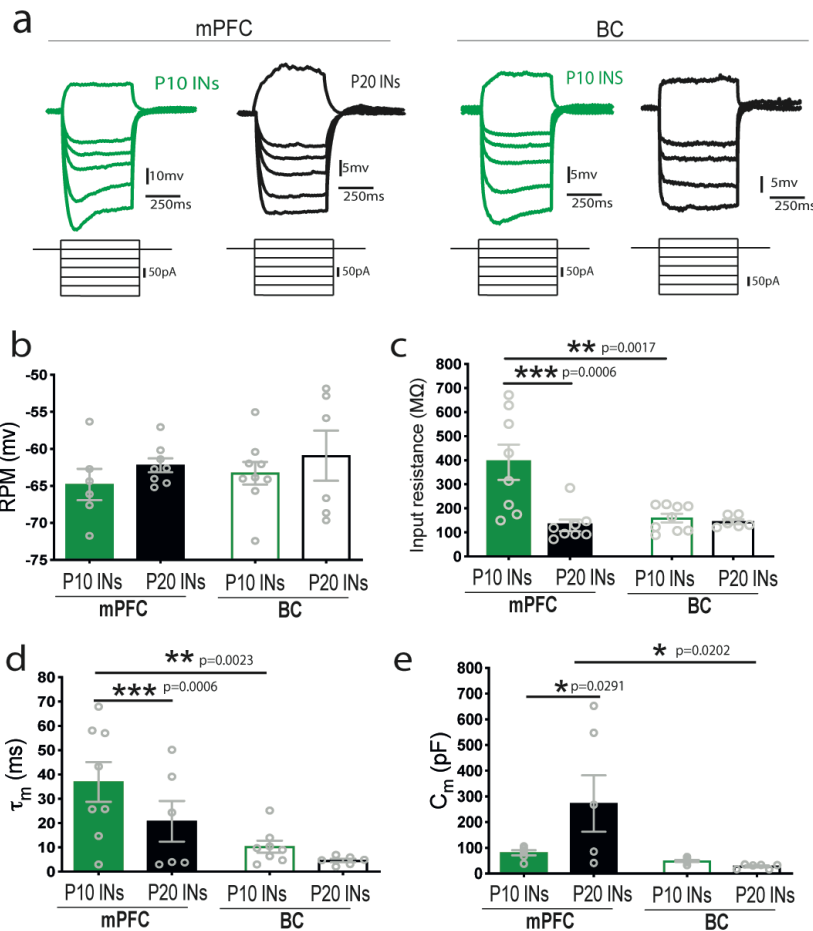

Figure 6. Passive membrane properties of Lhx6+ interneurons at P10 and P20 mPFC and P10 BC.

(a) Representative voltage responses (top traces) to 500ms positive and negative current pulses (bottom traces, +50, -50, -70, -100, -150, -200 pA) in mPFC at P10 and P20 and BC of Lhx6+ florescent interneurons from layer II/III.

(b) Bar graph showing the resting membrane potential (RMP) of interneurons at P10 and P20 in mPFC and BC. Two-way ANOVA analyses did not show any significant effect of age ($F_{(1,25)}$=1.55, p=0.22) or brain area ($F_{(1,25)}$=0.50, p=0.48) was found., (n=6-9 cells from 5-6 mice/age group).

(c) Bar graph showing the input resistance of interneurons at P10 and P20 in mPFC and BC. Two-way ANOVA analyses showed a significant effect of age ($F_{(1,27)}$=10.94, p=0.0027) and brain area ($F_{(1,27)}$=6.65 p=0.0157). Post-hoc analysis showed that the input resistance significantly decreased at P20 compared to P10 in mPFC (Tukey's test, p=0.0006) and was significantly higher in mPFC compared with BC, at P10 (Tukey's test, p=0.0017), (n=8-9 cells from 5-6 mice/age group).

39

1068 **(d)** Bar graph showing the membrane time constant (τ_m) of interneurons at P10 and P20 in

1069 mPFC and BC. Two-way ANOVA analyses showed a significant effect of age ($F_{(1,24)}$=14.71,

1070 p=0.0008) and brain area ($F_{(1,24)}$=6.92 p=0.0147). Post-hoc analysis showed that τ_m was

1071 significantly higher at P10 compared to P20 in mPFC (Tukey's test, p=0.0006) while it was

1072 significantly higher in mPFC compared to BC, at P10 (Tukey's test, p=0.0023), (n=8-9 cells from

1073 5-6 mice/age group).

1074 **(e)** Bar graph showing the membrane capacitance (C_m) of interneurons at P10 and P20 in mPFC

1075 and BC. Two-way ANOVA analyses showed a significant effect between brain areas ($F_{(1,21)}$=6.82,

1076 p=0.00163) and not between ages ($F_{(1,21)}$=2.60 p=0.1219). Post-hoc analysis showed that Cm was

1077 significantly higher at P10 compared with P20 in mPFC (Tukey's test, p=0.0291) and was not

1078 significantly different between mPFC and BC, at P10 (Tukey test, p=0.97) while it was significantly

1079 higher at P20 in mPFC compared to P20 in BC (Tukey test, p=0.0202), (n=6-9 cells from 5-6
1080 mice/age group).

1081

1082

1083

1084

1085

Figure 7

1087 **Figure 7. Significant differences in cellular density of Lhx6$^+$ interneurons in mPFC and BC at P10**

1088 **and P20.**

1089 **(a)** A representative immunostaining with GFP for Lhx6$^+$ interneurons in Lhx6-cre;ROSA26fl-

1090 STOPfl-YFP mice in mPFC and BC at P20 is showing on the left. Scale bars: 150 μm. On the right,

1091 bar graph comparing Lhx6$^+$ interneurons cell density (per mm^2) at P10 and P20 in mPFC and BC.

1092 Two-way ANOVA analyses of the cell density revealed a significant effect of brain area ($F_{(1, 18)}$ =

1093 13.11, p=0.0020), but not of age ($F_{(1,18)}$=0.7185, p=0.4078). Post-hoc analysis showed that the

1094 Lhx6$^+$ cell density was not significant different at P20 compared to P10 in mPFC and BC (LSD test,

1095 p=0.77 and p= 0.38, respectively). The Lhx6$^+$ cell density was significantly lower in mPFC

1096 compared to BC at P10 and P20, respectively (LSD test, p=0.0077 and p= 0.0440, respectively),

1097 (P10 in mPFC and BC:n= 5 mice, P20 in mPFC and BC: n=4).

1098 **(b)** A representative in situ hybridization staining for somatostatin positive cells (SST$^+$) using

1099 wild type animals in mPFC and BC at P20 is showing on the left. Scale bar: 200μm. Bar graph

1100 comparing cell density based on SST$^+$ expression at P10 and P20 in mPFC and BC. Two-way

1101 ANOVA analyses of the cell density showed no significant effect of age ($F_{(1, 13)}$= 2.78, p=0.12) and

1102 brain area ($F_{(1,13)}$=071, p=0.41) was found, (P10 in mPFC: n= 5 mice, P10 in BC and P20 in mPFC

1103 and BC: n=4).

1104 **(c)** A representative double immunostaining for GFP; PV (PV: parvalbumin) in mPFC and BC at

1105 P20 is showing on the left. Scale bars: 150 μm. On the right, bar graph comparing cell density

1106 based on PV$^+$ expression at P10 and P20 in mPFC and BC. Two-way ANOVA analyses of the cell

1107 density revealed a significant effect of age ($F_{(1, 14)}$ = 45.49, p<0.0001) and brain area ($F_{(1, 14)}$ =

1108 170.2, p<0.0001). PV$^+$ cells were not found in mPFC but were identified in BC, at P10. Post-hoc

1109 analysis showed that the PV$^+$ cell density was not significantly different at P20 compared to P10

1110 in BC (LSD test, p= 0.1089), but was significantly lower in mPFC compared to BC at P20 (LSD test,

1111 p<0.0001), (P10 and P20 in mPFC: n= 5 mice, P10 and P20 in BC: n=4).

1122 **Figure 8. Active properties of mPFC and BC pyramidal neurons.**

1123 **(a)** Representative traces of action potentials (APs) of layer II/III pyramidal neurons in mPFC

1124 (left) and BC (right) at P10 (green) and P20 (black), respectively.

1125 **(b)** Bar graph showing the AP amplitude of pyramidal neurons at P10 and P20 in mPFC and BC.

1126 Two-way ANOVA analyses showed a significant effect of age ($F_{(1, 31)}$ = 18.74, p=0.0001) but not

1127 on brain area ($F_{(1, 31)}$ = 0.99, p=0.32) was found. Post-hoc analysis showed that the AP amplitude

1128 significantly increased at P20 compared to P10 in mPFC and BC (Tukey's test, p=0.0386 and p=

1129 0.0131, respectively) (n=9-14 cells from 6-10 mice/age group).

1130 **(c)** Bar graph showing the AP rate of rise (dv/dt) of pyramidal neuron at P10 and P20 in mPFC

1131 and BC. Two-way ANOVA analyses showed a significant effect of age ($F_{(1,30)}$= 13.53, p=0.0009)

1132 but not on brain area ($F_{(1, 30)}$ = 0.36, p=0.55) was found. Post-hoc analysis showed that the AP

1133 rate of rise significantly increased at P20 compared to P10 in mPFC (Tukey's test, p= 0.0095), but

1134 not in BC (Tukey's test, p= 0.25) (n=8-14 cells from 6-10 mice/age group).

1135   **(d)** Bar graph showing the AP duration (half-width) of pyramidal neuron at P10 and P20 in mPFC

1136   and BC. Two-way ANOVA analyses showed no significant effect of age ($F(1, 33) = 0.52$, p=0.47)

1137   or brain area ($F_{(1, 33)} = 0.43$, p=0.51) was found (n=9-14 cells from 6-10 mice/age group).

1138   **(e)** Bar graph showing the AP rheobase of pyramidal neuron at P10 and P20 in mPFC and BC.

1139   Two-way ANOVA analyses showed no significant effect of age ($F_{(1, 36)} = 0.66$, p=0.41) or brain

1140   area ($F_{(1, 36)} = 0.16$, p=0.69) was found (n=9-14 cells from 6-10 mice/age group).

1141   **(f)** Bar graph showing the AP threshold of pyramidal neuron at P10 and P20 in mPFC and BC.

1142   Two-way ANOVA analyses showed no significant effect of age ($F_{(1,31)} = 1.90$, p=0.17) or brain area

1143   ($F_{(1,31)}=0.55$, p=0.46) was found (n=9-14 cells from 6-10 mice/age group).

1144

N1: control P10 model network, N2: pyramidal model neuron of P20 model network used, N3: fast-spiking interneuron model network of P20 model network used, N4: GABAAR reversal potential was set to -60mV (that of P20 model network).
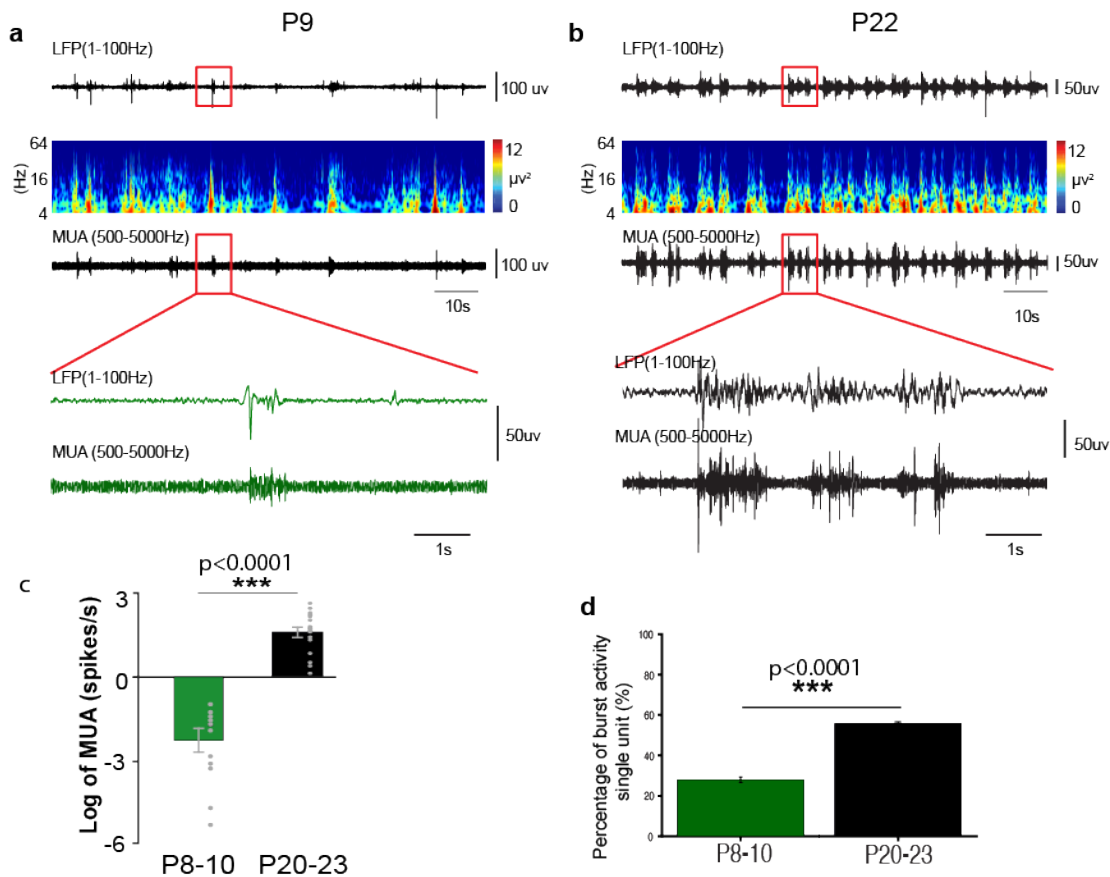

(g) Graph showing how the responses change in modified P20 model networks. J1: control P20 model network, J2: pyramidal model neuron of P10 model network used, J3: fast-spiking

1160   interneuron model network of P10 model network used, J4: GABAAR reversal potential was set

1161   to -40mV (that of P10 model network).

1162

Figure 10

Figure 10. Spike activity in PFC of neonatal and juvenile mice.

(a) Extracellular LFP recordings of oscillatory activity in PFC from a P9 mouse displayed after bandpass (1-100 Hz) filtering (top) and the corresponding MUA after bandpass (500-5000 Hz) filtering (bottom). Traces are accompanied by the color-coded wavelet spectra of the LFP at identical time scale.

(b) the same display as (**a**), but in one P22 mouse.

(c) Bar diagram displaying the mean MUA of neurons in PFC of neonatal and juvenile mice. During development, significant increase of MUA in PFC in juvenile mice (n=14) compared with in neonatal mice (n=13) (1.71±0.16 vs. -2.29±0.45, p<0.0001, One-way ANOVA, $F_{(1, 25)}$=80.19).

(d) Bar diagram displaying the percentage of the burst activity of single units in PFC of neonatal and juvenile mice. During development, significant more burst activity per single unit in PFC in juvenile mice (150 single unit) than in neonatal mice (161 single unit) (55.73±0.92 % vs. 27.90±1.41 %, p<0.0001, One-way ANOVA, F(1, 309)=272.26). In neonatal mice, 21 out 161 single

1178   units were classified as "burst unit". In juvenile mice, 104 out of 150 single units were classified

1179   as "burst unit".
