Nef enhances HIV-1 replication and infectivity independently of SERINC3 and SERINC5 in CEM T cells

Peter W. Ramirez, Aaron A. Angerstein, Marissa Suarez, Thomas Vollbrecht, Jared Wallace, Ryan M. O'Connell and John Guatelli

The authors have withdrawn their manuscript whilst they perform additional experiments to test some of their conclusions further. They found upon resequencing DNA from the cell lines used in their study that non-CRISPR edited genomes dominated the cultures. They believed they had confirmed complete editing in single-cell clones at the outset. Therefore, they are not confident based on their current experiments that the virologic effect of HIV-1 Nef is independent of SERINC3 and SERINC5 in T cells of the leukemic CEM line as they originally claimed. They are reengineering the cells to resolve this and apologize for any inconvenience that this has caused. Therefore, the authors do not wish this work to be cited as a reference for the project. If you have any questions, please contact the corresponding author.
