18 **Abstract**

19 Civets are small mammals belonging to the family *Viverridae*. The masked palm
20 civets (*Paguma larvata*) served as an intermediate host in the bat-to-human
21 transmission of severe acute respiratory syndrome coronavirus (SARS-CoV) in 2003¹.
22 Because of their unique role in the SARS outbreak, civets were suspected as a
23 potential intermediate host of SARS-CoV-2, the etiological pathogen of the
24 COVID-19 pandemic. Besides their susceptibility to coronaviruses, civets can also be
25 infected by other viruses, such as canine distemper viruses², parvoviruses³, influenza
26 viruses⁴, etc. Regarding the ecological and economical role of civets, it is vital to
27 evaluate the potential threats from different pathogens to these animals. Receptor
28 binding is a necessary step for virus entry into host cells. Understanding the
29 distribution of receptors of various viruses provides hints to their potential tissue

tropisms. Herein, we characterized the cell atlas of five important organs (the frontal lobe, lung, liver, spleen and kidney) of masked palm civets (*Paguma larvata*) and described the expression profiles of receptor associated genes of 132 viruses from 25 families, including 16 viruses from 10 families reported before that can attack civets and 116 viruses with little infection record.

Results

To build a comprehensive cell atlas of civet organs, we performed single-cell RNA sequencing to five organs of an adult male masked palm civet. After pre-processing, a total of 66,553 cells (Fig. 1a), including 6,593 cells from the frontal lobe, 13,009 cells from the lung, 34,883 cells from the liver, 10,138 cells from the spleen and 1,930 cells from the kidney were acquired. We conducted unsupervised clustering and annotated resulted cell clusters based on canonical markers (Fig. 1b-f, Table S1). In the frontal lobe, we identified 8 major cell types for 25 clusters, including astrocytes (AST), excitatory neurons (EX), inhibitory neurons (IN), oligodendrocytes (OLG), OLG progenitor cells (OPC), microglia (MG), smooth muscle cells (SMC), and endothelial cells (END). In lung, 7 cell types were annotated for 30 clusters, including pulmonary alveolar type I (AT1), pulmonary alveolar type II (AT2), macrophages (MAC), epithelial cells (EC), ciliated cells (CC), fibroblasts (FIB) and END. 5 cell types were characterized for 19 clusters in liver, including hepatic stellate cells (HSC), immune cells (IC), liver sinusoidal endothelial cells (LSEC), cholangiocytes and hepatocytes. In spleen, we annotated 21 clusters to 11 cell types, including END, FIB, neural cells (NEU), and several immune cell types, which were naive T cells, T cells, T follicular helper cells (Tfh), regulatory T cells (Treg), B cells, macrophages (MAC), dendritic cells (DC) and natural killer cells (NK). In kidney, 11 clusters were characterized to 8 cell types, including proximal tubule cells (PCT), distal convoluted tubule cells (DCT), podocytes (Podo), loop of Henle cells (LOH), collecting duct intercalated cells (CD-IC), collecting duct principal cells (CD-PC), pericytes (PER) and END. To share the single cell atlas of civet, we constructed an online platform, <http://120.79.46.200:81/Civet>, allowing researchers freely exploring our data set and

60 analysis results.

61

62 Among the viruses in analysis, we placed special focus on six virus families that
 63 prone to cause inter-species transmissions associated with severe diseases, including
 64 *Coronaviridae*, *Filoviridae*, *Orthomyxoviridae*, *Paramyxoviridae*, *Parvoviridae* and
 65 *Rhabdoviridae*, though no civet infections by filoviruses have yet been reported. For
 66 *Coronaviridae*, *ACE2*, the common receptor of SARS-CoV, SARS-CoV-2 and human
 67 coronavirus NL63, was expressed by a small fraction of cells in the frontal lobe, lung,
 68 liver, spleen and kidney, with the highest expression level in loop of Henle cells and
 69 proximal tubule cells of the kidney. *AXL*, the common receptor of SARS-CoV-2,
 70 ebolavirus and marburg marburgvirus, showed the same expression pattern as *ACE2*.
 71 Importantly, *NRP1*, another receptor for SARS-CoV-2, was widely detected in all five
 72 organs and expressed in a much higher level than *ACE2*. *ANPEP*, a common receptor
 73 for animal and human multiple coronaviruses, was only expressed by a small fraction
 74 of hepatocytes. For *Filoviridae*, multiple receptors (*ITCH*, *NPC1* and *MERTK*) of
 75 Ebola viruses and Marburg viruses displayed high expression in the five organs,
 76 though the expression levels varied among cell types. For *Orthomyxoviridae*, three
 77 receptor-associated genes for avian influenza A virus (*UVRAG*, *ANXA5* and *EGFR*)
 78 and one receptor-associated gene for bat influenza A virus H18N11 (*CD74*) showed
 79 high expression patterns in all five organs, especially in the lung and spleen. For
 80 *Paramyxoviridae*, *SLAMF1* and *NECTIN4* were both receptors of canine
 81 morbilliviruses but *SLAMF1* was detected in a small number of cells across the five
 82 organs while *NECTIN4* was only highly expressed by a few lung cells. *EFNB2* is a
 83 receptor of Henipaviruses, which was detected in all five organs with high
 84 expressions in the lung, spleen and kidney. For *Parvoviridae*, *TFRC*, which is a
 85 common receptor of parvoviruses, was widely expressed in the five organs with a
 86 significant enrichment in the endothelial cells of the frontal lobe. For *Rhabdoviridae*,
 87 the receptors of lyssaviruses, *GRM2* and *NCAM1*, were detected in all five organs
 88 with the highest expression in the frontal lobe. The receptors of vesicular stomatitis
 89 virus, *UVRAG* and *LDLR*, were identified in five organs with lung cells showing the

90 highest expressions (Fig. S1).

91

92 Besides the above six families, we also categorized the receptor distributions of other
93 viruses capable of infecting civets. *FIIR*, the receptor for viruses of *Caliciviridae* and
94 *Reoviridae*, was only detected in the civet lung (AT1 and AT2) and liver (liver
95 sinusoidal endothelial cells and hepatocytes). Another two receptors of reoviruses,
96 *RTN4R* and *ITGB1*, were both widely expressed in all five organs. *CXCR4*, a receptor
97 of feline immunodeficiency virus (*Retroviridae*), was widely detected in the frontal
98 lobe, lung, liver and spleen at low levels. *TLR8* and *TLR7*, the receptors of severe
99 fever with thrombocytopenia syndrome virus (*Bunyavirales*, *Phenuiviridae*), were
100 both found in the lung and spleen but *TLR8* was also distributed in the frontal lobe
101 and liver. The receptor of West Nile virus (*Flaviviridae*), *ITGAV*, showed expression
102 in all five organs (Fig. S2).

103

104 The receptor expressions of other viruses that have not been reported to infect civets
105 were also identified, including *Adenoviridae*, *Arenaviridae*, *Flaviviridae*,
106 *Hepadnaviridae*, *Herpesviridae*, etc. Multiple receptors for *Adenoviridae* (*WWP2*,
107 *CXADR*, *ITGB5* and *ITGAV*), *Herpesviridae* (*ITGB1*, *CR1*, *ITCH*, *ITGB8*, *ITGAV* and
108 *IDE*), *Picornaviridae* (*ITGAV*, *CXADR* and *ITGB8*) and *Reoviridae* (*ITGB1*, *HSPA8*
109 and *ITGAV*) were abundantly expressed by cells of the five organs. Expressions of the
110 other receptors tended to be lower than the above-mentioned ones or concentrated in
111 certain organs (Fig. S1, Fig. S2).

112 The receptor expression profiles could help us better clarify or predict the
113 pathological outcomes caused by viral infection in civets. For example, the canine
114 parvoviruses were reported to cause diarrhea and deaths in civets and the viral DNA
115 can be detected in the brain, liver, heart, spleen and small intestine³, which is
116 consistent with the wide distribution of its receptor *TFRC* in the civet organs.
117 Lyssaviruses usually cause fatal encephalitic diseases in a wide range of mammals
118 with civet infections reported in Africa and Asia^{5,6}. Our results showed an obvious

119 enrichment of a related receptor, *NCAM1*, in multiple cell types of the civet frontal
 120 lobe, which may contribute to the neurovirulence of these viruses. The receptor of
 121 SARS-CoV-2, ACE2, was only expressed at moderate levels in the kidney and flow
 122 cytometric experiment showed undetectable binding between the civet ACE2 ortholog
 123 and the viral receptor-binding domain. However, two alternative receptors, NRP1 and
 124 AXL, were both highly expressed in the lung and spleen, indicating potential
 125 susceptibility of civets to SARS-CoV-2, although *in vivo* infection remains unclear.

126 **Discussion**

127 Taken together, we have built a comprehensive multi-organ cell atlas of masked palm
 128 civet and described the distribution of various viral receptors in these tissues,
 129 providing preliminary evidence of the potential tissue tropism of these viruses in
 130 civets. The results could enhance our knowledge of the biological background of
 131 civets and their susceptibility to various pathogens, which may facilitate the control
 132 and prevention of enzootic and zoonotic viruses.
