21   **Abstract**

22   Severe COVID-19 is characterized by lung abnormalities, including the presence of syncytial

23   pneumocytes. Syncytia form when SARS-CoV-2 spike protein expressed on the surface of

24   infected cells interacts with the ACE2 receptor on neighbouring cells. The syncytia forming

25   potential of spike variant proteins remain poorly characterized. Here, we first assessed Alpha

26   and Beta spread and fusion in cell cultures. Alpha and Beta replicated similarly to D614G

27   reference strain in Vero, Caco-2, Calu-3 and primary airway cells. However, Alpha and Beta

28   formed larger and more numerous syncytia. Alpha, Beta and D614G fusion was similarly

29   inhibited by interferon induced transmembrane proteins (IFITMs). Individual mutations present

30   in Alpha and Beta spikes differentially modified fusogenicity, binding to ACE2 and recognition

31   by monoclonal antibodies. We further show that Delta spike also triggers faster fusion relative

32   to D614G. Thus, SARS-CoV-2 emerging variants display enhanced syncytia formation.

40   **Synopsis**

41   The Spike protein of the novel SARS-CoV-2 variants are comparative more fusogenic than the earlier

42   strains. The mutations in the variant spike protein differential modulate syncytia formation, ACE2

43   binding, and antibody escape.

44   • The spike protein of Alpha, Beta and Delta, in the absence of other viral proteins, induce more

45   syncytia than D614G

46   • The ACE2 affinity of the variant spike proteins correlates to their fusogenicity

47   • Variant associated mutations P681H, D1118H, and D215G augment cell-cell fusion, while

48   antibody escape mutation E484K, K417N and Δ242-244 hamper it.

49   • Variant spike-mediated syncytia formation is effectively restricted by IFITMs

Introduction

SARS-CoV-2 was initially discovered during an outbreak in Wuhan, China, before it became pandemic (Huang *et al*, 2020a). Since its emergence, the ancestral Wuhan strain has been supplanted by variants harboring a variety of mutations. Several of these mutations occur in the highly antigenic Spike (S) protein which endowed many of the variants with the ability to evade part of the neutralizing antibody response (Liu *et al*, 2021c; Planas *et al*, 2021a; Rees-Spear *et al*, 2021; Starr *et al*, 2021; Weisblum *et al*, 2020). Individual amino-acid changes in the S protein also affect viral fitness. One of the earliest identified variants contained the D614G mutation in S protein, which increased infectivity without significantly altering antibody neutralization (Yurkovetskiy *et al*, 2020). Several other variants have since emerged and have become globally dominant, including Alpha (B.1.1.7) first identified in the United Kingdom, Beta (B.1.351) identified in South Africa, Gamma (P.1 & P.2) identified in Brazil, and Delta (B.1.617.2) identified in India (Buss *et al*, 2021; Frampton *et al*, 2021; Planas *et al*, 2021b; Sabino *et al*, 2021; Tegally *et al*, 2020; Yadav *et al*, 2021). Some variants are more transmissible but their impact on disease severity is debated (Davies *et al*, 2021; Kemp *et al*, 2021; Korber *et al*, 2020).

Clinically, SARS-CoV-2 infections range from asymptomatic or febrile respiratory disorders to severe lung injury characterized by vascular thrombosis and alveolar damage (Bussani *et al*, 2020). The deterioration of respiratory tissue is likely a result of both virus-induced cytopathicity and indirect immune-mediated damage (Buchrieser *et al*, 2020; Zhang *et al*, 2020; Zhou *et al*, 2020; Zhu *et al*, 2020). A peculiar dysmorphic cellular feature is the

5

71   presence of large infected multinucleated syncytia; predominately comprised of pneumocytes

72   (Braga *et al*, 2021; Bussani *et al.*, 2020; Sanders *et al*, 2021). Other coronaviruses including

73   SARS-CoV-1, MERS-CoV, and HKU1 also induce syncytia formation in patient tissues and cell

74   culture systems (Chan *et al*, 2013; Dominguez *et al*, 2013; Franks *et al*, 2003; Qian *et al*, 2013).

75   Syncytial cells may compound SARS-CoV-2 induced cytopathicity, play a role in viral persistence

76   and dissemination and could be a pathological substrate for respiratory tissue damage (Braga *et*

77   *al.*, 2021; Buchrieser *et al.*, 2020; Sanders *et al.*, 2021). Release of syncytial cells may contribute

78   to the overall infectious dose (Beucher *et al*, 2021). Heterocellular syncytia containing

79   lymphocytes have also been documented in the lungs of infected patients (Zhang *et al*, 2021).

80   The SARS-CoV-2 S protein is a viral fusogen. The interaction of trimeric S with the ACE2

81   receptor and its subsequent cleavage and priming by surface and endosomal proteases results

82   in virus-cell fusion (Hoffmann *et al*, 2020). Merging of viral and cellular membranes allows for

83   viral contents to be deposited into the cell to begin the viral life cycle. Within the cell, newly

84   synthesized spike, envelope and membrane proteins are inserted into the endoplasmic

85   reticulum (ER), and trafficked and processed through the ER-Golgi network (Cattin-Ortolá *et al*,

86   2021; Duan *et al*, 2020; Nal *et al*, 2005). Virion are formed by budding into ER-Golgi membranes

87   and are then transported to the surface in order to be released from the cell (Klein *et al*, 2020).

88   While the majority of the S protein is sequestered within the ER, motifs within its cytoplasmic

89   tail allow for leakage from the Golgi apparatus and localization at the plasma membrane

90   (Cattin-Ortolá *et al.*, 2021). The S protein at the surface of an infected cell interacts with

91   receptors on adjacent cells, fusing the plasma membranes together and merging the

92   cytoplasmic contents. We and others had previously shown that the S protein interacting with

93   the ACE2 receptor induces cell-cell fusion (Braga *et al.*, 2021; Buchrieser *et al.*, 2020; Lin *et al*,

94   2021; Sanders *et al.*, 2021; Zhang *et al.*, 2021).The TMPRSS2 protease further augments cell-cell

95   fusion (Barrett *et al*, 2021; Buchrieser *et al.*, 2020; Hornich *et al*, 2021).

96   The S protein is comprised of S1 and S2 subunits. The S1 subunit includes the N-terminal

97   domain (NTD) and the receptor binding domain (RBD). The function of the NTD has yet to be

98   fully elucidated but it may be associated with glycan binding, receptor recognition and pre-

99   fusion-to-post fusion conformational changes. The NTD is also targeted by neutralizing

100   antibodies (Chi *et al*, 2020; Krempl *et al*, 1997; Zhou *et al*, 2019). The RBD interacts with the

101   ACE2 receptor and is the main target for neutralizing antibodies (Huang *et al*, 2020b). The S2

102   domain consists of the fusion peptide (FP), heptapeptide repeat sequences 1 and 2, (HR1 and

103   HR2), the transmembrane anchor, and the C-terminal domain. The FP inserts into the target

104   membrane by disrupting the lipid bilayer and anchors the target membrane to the fusion

105   machinery (Huang *et al.*, 2020b). This exposes regions of HR1 that interact with HR2, forming a

106   flexible loop that brings the membranes together to facilitate fusion (Huang *et al.*, 2020b). The

107   versatility of the S protein suggests that any mutations that have arisen are of particular

108   concern as they can affect fusogenicity, antibody recognition, affinity to ACE2, proteolytic

109   processing and incorporation into virions. There is a general paucity of information regarding

110   how the mutations associated with variant S proteins contribute to cell-cell fusion.

111   S-mediated cell-cell fusion is sensitive to innate immunity components. The interferon

112   response to SARS-CoV-2 is one of the key factors down-modulating viral entry and replication,

113 and deficiencies in the interferon response are associated with severe or critical COVID-19

114 (Arunachalam *et al*, 2020; Bastard *et al*, 2021; Bastard *et al*, 2020; Hadjadj *et al*, 2020; van der

115 Made *et al*, 2020). SARS-CoV-2 induced syncytia formation by the Wuhan strain is restricted by

116 innate immunity, in part through the action of interferon induced transmembrane proteins

117 (IFITMs) (Buchrieser *et al.*, 2020). IFITM1, 2 and 3 are restriction factors which display antiviral

118 activity against a variety of enveloped viruses including SARS-CoV-2; likely by increasing

119 membrane rigidity and hindering virus-cell fusion (Shi *et al*, 2021). Their effectiveness at

120 restricting cell-cell fusion of novel variants has yet to be assessed.

121 Here, we compared the replication and syncytia forming potential of D614G, Alpha and

122 Beta viruses in human cell lines and primary airway cells. We further characterized the

123 fusogenicity of the Alpha and Beta variant S proteins and the individual contribution of each of

124 the component mutations in syncytia formation, ACE2 binding and evasion from a panel of

125 antibodies. Finally, we examined the syncytia forming potential and ACE2 binding capacity of

126 the novel Delta variant spike.

127

128 **Results**

129 **Comparative Replication Kinetics of SARS-CoV-2 Variants**

130 We compared the replication kinetics of SARS-CoV-2 variants in relevant cell cultures.

131 We first infected Caco-2, Calu-3 and Vero cells with Alpha, Beta, and D614G variants and

132 generated multistep growth curves **(Fig. 1)**. Cell were infected at an equivalent, non-saturating

8

133   MOI, initially titrated in Vero cells **(Fig. EV1A)**. Viral replication was assessed at 24, 48, and 72

134   hours by flow cytometry upon staining with the pan-SARS-CoV-2 anti-S mAb102 human

135   monoclonal antibody (Planas *et al.*, 2021a) and then gating for S+ cells **(Fig. EV1B)**. Globally, the

136   variants replicated similarly **(Fig. 1)**. This similar replication was observed at different MOIs **(Fig.**

137   **EV1A)**. There were subtle differences at 24h post-infection, depending on the cell line and the

138   variant. For instance, Beta replicated slightly more than D614G in Caco-2 cells whereas Alpha

139   replicated slight less than D614G in Vero cells **(Fig. 1A, C)**. Viral release at each time point was

140   also assessed by extracting RNA from the supernatant and performing RT-qPCR for the gene

141   encoding the N protein. Viral release was again roughly similar with the different variants,

142   especially at early time points. Alpha produced moderately more virus than D614G in all cell

143   lines at later time points **(Fig. 1A-C).** Beta produced more virus than D614G in Caco-2 but less in

144   Calu-3 cells at later time points **(Fig. 1A, B)**.

145   We then used the MucilAirB^{TM} model, which consists of primary human airway epithelial

146   cells (HAEC) grown over a porous membrane and differentiated at the air-liquid interface for

147   over 4 weeks. This relevant model is susceptible to SARS-CoV-2 infection (Pizzorno *et al*, 2020;

148   Robinot *et al*, 2020; Robinot *et al*, 2021; Touret *et al*, 2021). The cells were infected with each

149   variant at a similar low viral inoculum (10^4 TCID50). Viral RNA and infectious virus release were

150   monitored over 96h by RT-qPCR and TCID50. Alpha and Beta variants produced slightly more

151   extracellular viral RNA than D614G at later time points but not significantly higher levels of

152   infectious particles **(Fig. 1D)**.

9

153   Taken together our data show that Alpha and Beta variants replicate similarly to the

154   ancestral D614G strain in a panel of human cell lines and in primary cells, with some slight

155   differences.

156   **Syncytia formation in cells infected with SARS-CoV-2 variants.**

157   We next assessed the potential of SARS-CoV-2 variants to induce syncytia. In order to

158   visualize cell-cell fusion, we employed our previously described S-Fuse assay, using U2OS-ACE2

159   GFP-split cells (Buchrieser *et al.*, 2020). In the GFP-split complementation system, two cell lines

160   containing half of the reporter protein are co-cultured, producing a GFP signal only upon fusion

161   **(Fig. 2A).** Upon infection of S-Fuse cells, we noticed that the Alpha and Beta variants formed

162   larger and more numerous infected syncytia than either D614G or the ancestral Wuhan strain

163   **(Fig. EV2A).** We then characterized quantitatively the differences in fusogenicity by calculating

164   the total syncytia (GFP) area and then normalizing it to nuclei number (Hoechst) **(Fig. EV2B)**.

165   Relative to D614G, Alpha and Beta variants produced significantly more syncytia, approximately

166   4.5 and 3-fold respectively, after 20h of infection with the same MOI **(Fig. 2B and EV3A)**. In

167   order to characterize syncytia formation in a cell line expressing endogenous ACE2, we

168   generated Vero cells carrying the GFP-split system. After 48h of infection with the same MOI,

169   we again found that Alpha and Beta variants produced significantly more syncytia than D614G

170   **(Fig. 2C and EV3B)** despite similar infection levels **(Fig. 1C)**. Of note, D614G produced similar

171   levels of syncytia as the Wuhan strain in both Vero and S-Fuse cells (**Fig. 2 and EV3A-B**).

172   Therefore, Alpha and Beta variants appear more fusogenic than D614G in S-Fuse and

173   Vero cells.

10

174

Syncytia formation in cells expressing variant Spikes.

176   Since syncytia formation is a consequence of the S protein expressed on the surface of

177   an infected cell interacting with ACE2 receptors on neighboring cell, we sought to compare the

178   fusogenic potential of the individual variant S proteins. We introduced the D614G mutation into

179   the Wuhan protein and designed plasmids to express Alpha and Beta S proteins. We

180   transfected the respective plasmids into Vero GFP-split cells and quantified syncytia formation

181   18h later **(Fig. 3A)**. Alpha and Beta S proteins were 2 and 1.7-fold more fusogenic than D614G S,

182   respectively **(Fig. 3B)**. The Wuhan S was slightly less fusogenic that the D614G S **(Fig. 3B)**. We

183   then verified that the variation in S mediated fusion was not due to differential cell surface

184   levels. We transfected 293T cells, which lack ACE2 and thus do not fuse upon S expression, with

185   the different variant plasmids in order to assess S protein surface levels by flow cytometry. The

186   variants S proteins were equally expressed after transfection **(Fig. EV4A-C).**

187   We then measured the kinetics of syncytia formation induced by the different S proteins

188   in Vero GFP-Split cells. We conducted a comparative video-microscopy analysis where cell-cell

189   fusion could be visualized as soon as 6h post-transfection. The fusion kinetics of Alpha S protein

190   was more rapid than any of the other variants **(Fig. 3C and Movie E1)**. Beta also induced

191   significantly faster fusion than D614G, whereas the Wuhan S was the slowest of all the

192   compared proteins **(Fig. 3C and Movie E1)**.

193   We then asked whether the TMPRSS2 protease, that cleaves S and facilitate viral fusion,

194   may act differently on the variant S proteins. To this aim, we expressed the different variant S

195   proteins without or with TMPRSS2 in 293T cells. We examined the processing of the different S

196   by western blot and the surface levels by flow cytometry. The cleavage profile induced by

197   TMPRSS2 and the surface levels of the different variant S proteins were similar **(Fig EV4E)**.

198   Altogether, our data indicate that the S proteins of Alpha and Beta variants form more syncytia

199   than D614G or Wuhan strains.

200   **Restriction of S mediated syncytia formation by IFN-β1 and IFITMs.**

201   As the variants did not show any major difference in replication under basal conditions,

202   we next investigated if they were differently sensitive to the interferon response. To this aim,

203   we pre-treated Vero cells or U2OS-ACE2 (S-Fuse) cells with increasing doses of IFN-β1 and

204   infected them with the different variants. IFN-β1 was equally effective at reducing viral

205   replication of D614G, Alpha, and Beta variants in Vero cells **(Fig. EV5A)**. Preincubation of S-Fuse

206   cell with IFN-β1 also abrogated infection and syncytia formation to the same extent with the

207   different variants (**Fig. EV5B**). Therefore, IFN-β1 similarly inhibited viral replication and reduced

208   syncytia formation by D614G, Alpha and Beta variants.

209   IFITMs are interferon stimulated transmembrane proteins that restrict early stages of the viral

210   life cycle by inhibiting virus-cell fusion; likely by modifying the rigidity or curvature of

211   membranes (Compton *et al*, 2014; Shi *et al*, 2017; Zani & Yount, 2018). IFITM1 localizes at the

212   plasma membrane while IFITM2 and 3 transit through surface and localize in endo-lysosomal

12

213   compartments (Buchrieser *et al.*, 2020). We previously reported that IFITMs restrict Wuhan S

214   mediated cell-cell fusion and that their activity was counteracted by the TMPRSS2 protease

215   (Buchrieser *et al.*, 2020). As infection with Alpha and Beta induce more syncytia, we further

216   investigated if this resulted in an increased resistance to IFITM restriction. We thus

217   characterized the impact of IFITMs on syncytia formed upon expression of D614G, Alpha and

218   Beta S proteins in 293T cells. The variants were effectively restricted by IFITMs **(Fig. EV5C-G)**. Of

219   note, the three IFITMs were expressed at similar levels (not shown). The presence of TMPRSS2

220   increased fusion of all S proteins and reverted the restriction by IFITMs **(Fig. EV5C-G)**. Taken

221   together, our data show that Alpha and Beta variants induce more syncytia, but their S proteins

222   remain similarly sensitive to IFITMs.

223

224   **Contribution of individual variant-associated mutations on Spike fusogenicity.**

225   We next sought to determine the contribution of each variant-associated mutation to

226   cell-cell fusion. Both Alpha and Beta S proteins contain the N501Y mutation in the RBD and the

227   D614G mutation in the S1/S2 cleavage site **(Fig. 4A)**. Alpha S contains the Δ69/70 and ΔY144

228   deletions in the N-terminal domain (NTD), P681H and T716I mutations in the S1/S2 cleavage

229   site, the S982A mutation in the heptad repeat 1 (HR1) site and the D1118H mutation in

230   between HR1 and HR2. The Beta S is comprised of the L18F, D80A, D215G and Δ242-244

231   mutations in the NTD, K417N and E484K mutations in the receptor binding domain (RBD), and

232   A701V in the S1/S2 cleavage site. We introduced individual mutations into the D614G

233   background. Following reports of the emergence of the E484K mutation within the Alpha

13

234   variant (Collier *et al*, 2021), we also generated a mutant Alpha S protein with the E484K

235   mutation. We observed by flow cytometry that the mutant S proteins were similarly expressed

236   at the cell surface **(Fig. EV4A-C and EV6 A-D)**. We expressed each mutant into Vero GFP split

237   and measured their potential to induce cell-cell fusion in comparison to D614G S protein.

238   Of the mutations that are associated with Alpha, we found that the Δ69/70 deletion in

239   the RBD decreased cell-cell fusion whereas P681H and D1118H substitutions both increase

240   fusion **(Fig. 4A and EV6G)**. P681H displayed the greatest fusogenicity of all investigated

241   mutations, being almost 2.5-fold higher than D614G S **(Fig. 4A and EV6G).** As previously

242   mentioned, the introduction of the D614G mutation in the S1/S2 border of the Wuhan S

243   protein also relatively increased fusion, stressing the importance of this cleavage site in

244   fusogenicity **(Fig. 3B)**.

245   Among the mutations associated with Beta, the Δ242-244 deletion, as well as K417N

246   and E484K mutations in the RBD significantly decreased syncytia formation **(Fig. 4A and EV6H)**.

247   Only the D251G mutation in the NTD modestly increased syncytia formation relative to D614G

248   **(Fig. 4A and EV6H)**. The introduction of the E484K RBD mutation into the Alpha S protein

249   significantly decreased its potential to form syncytia, despite not changing cell surface

250   expression, further supporting the mutation's restrictive effect on cell-cell fusion **(Fig. 4B and**

251   **EV4B)**. Taken together, our data suggests that variant S proteins are comprised of mutations

252   that play contrasting roles in cell-cell fusion. P681H, D1118H, and D215G substitutions facilitate

253   fusion, whereas mutations Δ69/70, Δ242-244, K417N, and E484K antagonize cell-cell fusion.

254

14

Binding of S proteins bearing individual variant-associated mutations to ACE2.

255

256   We next explored the impact of variant-associated mutations on S binding to the ACE2

257   receptor. To this aim, we transiently expressed each mutant protein in 293T cells. Cells were

258   then stained with a serial dilution of soluble biotinylated ACE2, revealed with fluorescent

259   streptavidin and then analyzed by flow cytometry **(Fig. 5A)**. Titration binding curves were

260   generated and EC50 (the amount of ACE2 needed for 50% binding) was calculated. The S

261   protein of Alpha had the highest affinity to ACE2, confirming previous results by us and others

262   (Planas *et al.*, 2021)(Ramanathan *et al*, 2021). Alpha was sequentially followed by Beta, D614G,

263   and Wuhan S **(Fig. 5B and EV7A)**. As expected, mutations within the RBD had the most

264   significant impact on ACE2 binding. N501Y found in both Alpha and Beta drastically increased

265   ACE2 binding, in line with previous reports indicating that this mutation enhances affinity of the

266   viral protein to its receptor (Ali *et al*, 2021; Luan *et al*, 2021; Tian *et al*, 2021). The K417N

267   substitution present in the Beta S decreased ACE2 binding **(Fig. 5B and EV7C)**. The E484K

268   mutant had a slightly, but not significantly, higher binding to ACE2 **(Fig. EV7C)**. This was

269   corroborated by the observation that addition of the E484K mutation to Alpha S protein also

270   slightly increased ACE2 binding **(Fig. 5B and EV7A)**. Mutation in the S1/S2 cleavage site,

271   HR1/HR2 sites or NTD did not have any significant impact on ACE2 binding **(Fig. 5B and EV7B-E)**.

272   It is worth noting that the NTD Δ242-244 mutant displayed a marginally lower binding to ACE2

273   **(Fig. 5B and EV7B)**. Therefore, the N501Y mutation is the most significant contributor to

274   increased ACE2 binding of the variants, though it does not affect cell-cell fusion on its own. The

15

275   K417N, Δ242-244, and E484K mutations restrict fusogenicity but differently effect ACE2

276   binding; with the former two decreasing affinity and the latter slightly increasing.

277   Therefore, ACE2 binding and fusogenicity are two functions of the S protein that can be

278   partially deconvoluted through individual mutations.

279

280   **Antibody binding to S proteins bearing individual variant-associated mutations.**

281   We had previously found that certain neutralizing antibodies differentially affect SARS-

282   CoV-2 D614G, Alpha and Beta variants (Planas *et al.*, 2021a). For instance, neutralizing

283   monoclonal antibody 48 (mAb48) restricts D614G virus but not Alpha or Beta variants (Planas *et*

284   *al.*, 2021a). We sought to determine which mutations in variant S proteins contributed to the

285   lack of recognition by the neutralizing antibodies. To this aim, we assessed by flow cytometry

286   the binding of a panel of four human monoclonal antibodies (mAbs) to the different S mutants.

287   As a control we used mAb10, a pan-coronavirus antibody that targets an unknown but

288   conserved epitope within the S2 region (Planchais, manuscript in preparation). mAb10 equally

289   recognized all variants and associated individual mutations **(Fig. 5C)**. mAb48 and mAb98 target

290   the RBD and mAb71 the NTD (Planas *et al.*, 2021b)(Planchais, manuscript in preparation).

291   mAb48 did not recognize the Beta variant, and more specifically did not bind to the K417N

292   mutant **(Fig. 5C)**. The mAb71 recognized neither Alpha nor Beta variants and did not bind to

293   their respective NTD ΔY144 and Δ242-244 mutations. The K417N and Δ242-244 mutations were

294   also responsible for decreasing S-mediated fusion, suggesting a tradeoff between antibody

16

295   escape and fusion **(Fig. 5C)**. mAb98 did not recognize the Beta variant. However, none of the

296   associated mutations were specifically responsible for the lack of binding **(Fig. 5C)**, suggesting a

297   combined effect on the structure of the S protein that may affect antibody escape.

298   Therefore, several of the mutations found in the variants spike proteins are

299   advantageous in terms of antibody escape despite slightly reducing the ability the proteins to

300   fuse.

301   **Spike mediated syncytia formation by the Delta variant.**

302   With the emergence and rapid spread of the Delta variant, we sought to characterize its

303   potential to form syncytia. We recently showed that the Delta variant induce large syncytia in S-

304   Fuse cells (Planas *et al.*, 2021b). We thus compared the fusogenicity of the Delta S protein to

305   that of D614G and Alpha. We transiently expressed the three S proteins in Vero-GFP split cells.

306   The Delta S protein triggered more cell-cell fusion than the D614G variant but was similar to the

307   Alpha S protein **(Fig 6A).** The fusion kinetic of the Delta S was also similar to Alpha but more

308   rapid than D614G **(Fig 6B).** We confirmed that the variant S proteins were equally expressed on

309   the surface by transfecting them into non-fusogenic 293T cells and performing flow cytometry

310   upon staining with the pan-SARS-CoV-2 mAb129 (**Fig EV4D**). We next examined the ACE2

311   binding potential of Delta S protein using our aforementioned soluble biotinylated ACE2. The

312   Delta S protein has a higher binding capacity to ACE2 than the D614G S protein, but the binding

313   was lower than the Alpha S protein **(Fig 6C)**.

314

17

315   **Discussion**

316   The replication and cytopathic effects of SARS-CoV-2 variants is under intense scrutiny,

317   with contrasting results in the literature (Frampton *et al.*, 2021; Hou *et al*, 2020; Leung *et al*,

318   2021; Liu *et al*, 2021b; Touret *et al.*, 2021). For instance, there was no major difference in the

319   replication kinetics of Alpha and D614G strains in some reports (Thorne *et al*, 2021; Touret *et*

320   *al.*, 2021), whereas others suggested that Alpha may outcompete D614G in a co-infection assay

321   (Touret *et al.*, 2021). Other studies proposed that the N501Y mutation may provide a

322   replication advantage, whereas others suggested that N501Y is deleterious (Frampton *et al.*,

323   2021; Hou *et al.*, 2020; Leung *et al.*, 2021; Liu *et al.*, 2021b). These discrepant results may be

324   due to the use of different experimental systems, viral strains, multiplicities of infection and cell

325   types.

326   Here, we show that Alpha and Beta variants replicate to the same extent as the early

327   D614G strain in different human cell lines and primary airway cells. Moreover, Alpha and Beta

328   induced more cell-cell fusion than D614G. Increased fusion was observed in U2OS-ACE2 cells

329   and in naturally permissive Vero cells. In agreement with infection data, transfection of Alpha

330   and Beta S proteins, in the absence of any other viral factors, produced significantly more

331   syncytia than D614G, which in turn, fused more than the Wuhan S. Comparative video

332   microscopy analysis revealed that Alpha S fused the most rapidly, followed by Beta, D614G, and

333   finally Wuhan. Thus, Alpha and Beta variants display enhanced S-mediated syncytia formation.

334   We further show that Alpha and Beta remain sensitive to restriction by IFN-β1. The

335   fusion mediated by their respective S proteins is inhibited by IFITMs. This extends previous

336   results by us and others demonstrating that ancestral Wuhan S is effectively inhibited by this

337   family of restriction factors (Buchrieser *et al.*, 2020; Shi *et al.*, 2021). It has been recently

338   reported in a pre-print that Alpha may lead to lower levels of IFN-β1 production by infected

339   Calu-3 cells and may be less sensitive to IFN-β pre-treatment, when compared to first wave viral

340   isolates (Thorne *et al.*, 2021). We did not detect here differences of IFN-β1 sensitivity between

341   the variants in Vero and U2OS-ACE2 cells. Again, these discrepant results may reflect inherent

342   differences between Calu-3, Vero and U2OS-ACE2 cells, or the use of different viral isolates.

343   We then characterized the contribution of the individual mutations present in Alpha and

344   Beta S proteins to their respective fusogenicity. The highly fusogenic Alpha S consists of more

345   mutations that robustly increase fusion (P681H and D1118H) than mutations that decrease

346   fusion (Δ69/70). In contrast, the Beta variant is comprised of several restrictive mutations

347   (Δ242-244, K417N, and E484K) and only one mutation that modestly increased fusion (D215G).

348   The strongest increase in fusion was elicited by the P681H mutation at the S1/S2 border. This

349   mutation likely facilitates proteolytic cleavage of S and thus promotes S mediate cell-cell fusion.

350   Indeed, the analogous P681R mutation present in B.1.617.2 and B.1.617.3 variants increases

351   S1/S2 cleavage and facilitates syncytia formation (Ferreira *et al*, 2021; Jiang *et al*, 2020). Of

352   note, another report with indirect assessment of variant S fusogenicity suggested a mild

353   decrease or no difference in cell-cell fusion of Alpha and Beta relative to Wuhan S (Hoffmann *et

354   al*, 2021). These previous experiments were performed in 293T cells at a late time-points (24

355   hours post-transfection), which may preclude detection of an accelerated fusion triggered by

356   the variants.

357   We show that the binding of variant S to soluble ACE2 paralleled their fusogenicity.

358   Alpha bound the most efficiently to ACE2, followed by Beta, D614G and finally Wuhan.

359   However, the ACE2 affinity of S proteins carrying individual mutations did not exactly correlate

360   to fusogenicity. For instance, the N501Y and D614G mutations drastically increased ACE2

361   affinity, but only D614G enhanced fusogenicity. The K417N substitution, and to a lesser degree

362   Δ242-244, had a lower affinity to ACE2 and also restricted cell-cell fusion. The E484K mutation

363   significantly restricts fusion, but mildly increases ACE2 affinity. This suggests that on the level of

364   individual S mutations, the relationship between ACE2 affinity and increased fusogenicity is not

365   always linear. Variant mutations may also confer advantages in an ACE2 independent manner.

366   Indeed, recent work has suggested that the E484 mutation may facilitate viral entry into H522

367   lung cells, requiring surface heparan sulfates rather than ACE2 (Puray-Chavez *et al*, 2021). It

368   would be of future interest to examine the syncytia formation potential of the variant

369   mutations in other cell types.

370   We selected a panel of 4 mAbs that displayed different profiles of binding to Alpha,

371   Beta, D614G and Wuhan S proteins. The mAb10 targeting the S2 domain recognized all variants

372   and was used as a positive control. Wuhan and D614G were recognized by the three other

373   antibodies, targeting either the NTD or RBD. Alpha lost recognition by the anti-NTD mAb71,

374   whereas Beta was neither recognized by mab71 nor by the two anti-RBD antibodies mAb48 and

375   mAb 98. Upon examining the potential of S proteins carrying individual mutations to bind to

376   human monoclonal antibodies, we found that the ones that restrict (Δ242-244, K417N) or have

377   no effect on fusogenicity (ΔY144) are also not recognized by some mAbs. This suggests that

378 variant S proteins have undergone evolutionary trade off in some circumstances; selecting for

379 mutations that provide antibody escape at the detriment of fusogenicity. In accordance with

380 our findings, deep sequence binding analysis and in vitro evolution studies suggest the N501Y

381 mutation increases affinity to ACE2 without disturbing antibody neutralization (Liu *et al*, 2021a;

382 Starr *et al.*, 2021; Zahradník *et al*, 2021). The E484K and K417N RBD mutations in the Beta

383 variant may also increase ACE2 affinity, particularly when in conjunction with N501Y (Zahradník

384 *et al.*, 2021) (Nelson *et al*, 2021). However, the resulting conformational change of the S protein

385 RBD may also decrease sensitivity to neutralizing antibodies (Nelson *et al.*, 2021). Future work

386 assessing the structural and conformational changes in the S protein elicited by a combination

387 of individual mutations or deletions may further help elucidate the increased fusogenicity and

388 antibody escape potential of the variants.

389   While we had previously shown that the interaction between the S protein on the

390 plasma membrane with the ACE2 receptor on neighboring cells is sufficient to induce syncytia

391 formation, there is compelling evidence of the importance of the TMPRSS2 protease in S

392 activation (Buchrieser *et al.*, 2020; Dittmar *et al*, 2021; Koch *et al*, 2021; Ou *et al*, 2021). We did

393 not detect any major differences in the processing of the variant spike proteins by TMPRSS2. It

394 will be worth further characterizing how the fusogenicity of variant associated mutations are

395 influenced by other cellular proteases.

396   The presence of infected syncytial pneumocytes was documented in the lungs of

397 patients with severe COVID-19 (Bussani *et al.*, 2020; Tian *et al*, 2020; Xu *et al*, 2020). Syncytia

398 formation may contribute to SARS-CoV-2 replication and spread, immune evasion and tissue

399   damage. A report using reconstituted bronchial epithelia found that viral infection results in the

400   formation and release of infected syncytia that contribute to the infectious dose (Beucher *et al.*,

401   2021). The neutralizing antibody response to SARS-CoV-2 infection has divergent effect on cell-

402   cell fusion, with some antibodies restricting S mediated fusion, while other increase syncytia

403   formation (Asarnow *et al*, 2021). Cell-to-cell spread of virus may be less sensitive to

404   neutralization by monoclonal antibodies and convalescent plasma than cell-free virus (Jackson

405   *et al*, 2021). It is thus possible that infected syncytial cells facilitate viral spread. Within this

406   context, it is necessary to better understand the fusogenic potential of the SARS-CoV-2 variants

407   that have arisen and will continue to emerge.

408   We have characterized here the replication, fusogenicity, ACE2 binding and antibody

409   recognition of Alpha and Beta variants and the role of their S-associated mutations. Despite the

410   insights we provide into the S-mediated fusogenicity of the variants, we did not address the

411   conformational changes that the mutations individually or in combination may elicit. We

412   further show that Alpha, Beta and Delta spike proteins more efficiently bind to ACE2 and are

413   more fusogenic than D614G. Which virological and immunological features of the Delta variant

414   explain its higher estimated transmissibility rate than Alpha and other variants at the

415   population level remains an outstanding question.

421

422

423

Material and Methods

425

Plasmids

427 A codon optimized version of the reference Wuhan SARS-CoV-2 Spike (GenBank: QHD43416.1)

428 was ordered as a synthetic gene (GeneArt, Thermo Fisher Scientific) and was cloned into a

429 phCMV backbone (GeneBank: AJ318514), by replacing the VSV-G gene. The mutations for Alpha

430 and Beta (**Fig. 4A**) were added in silico to the codon-optimized Wuhan strain and ordered as

431 synthetic genes (GeneArt, Thermo Fisher Scientific) and cloned into the same backbone (Planas

432 *et al.*, 2021a). The D614G S-protein was generated by introducing the mutation into the Wuhan

433 reference strain via Q5 Site-directed mutagenesis (NEB). Other individual mutations were

434 subsequently introduced into the D614G S by the same process. Plasmids were sequenced prior

435 to use. The primers used for sequencing and the site-directed mutagenesis are presented in the

436 supplement **(EV Tables 1 and 2)**. pQCXIP-Empty control plasmid, pQCXIP-IFITM1-N-FLAG,

23

437   pQCXIP-IFITM2-N-FLAG, pQCXIP-IFITM3-N-FLAG were previously described (Buchrieser *et al*,

438   2019). pQCXIP-BSR-GFP11 and pQCXIP-GFP1-10 were from Yutaka Hata ((Kodaka *et al*, 2015);

439   Addgene plasmid #68716; http://n2t.net/addgene:68716; RRID: Addgene_68716 and Addgene

440   plasmid #68715; http://n2t.net/addgene:68715; RRID: Addgene_68715). pcDNA3.1-hACE2 was

441   from Hyeryun Choe ((Li *et al*, 2003); Addgene plasmid # 1786; http://n2t.net/addgene:1786;

442   RRID: Addgene_1786). pCSDest-TMPRSS2 was from Roger Reeves ((Edie *et al*, 2018); Addgene

443   plasmid # 53887; http://n2t.net/addgene:53887; RRID: Addgene_53887).

444   **Cells**

445   Vero E6, HEK293T, U2OS, Caco2/TC7, Calu3 were cultured in DMEM with 10% Fetal Bovine

446   Serum (FBS) and 1% Penicillin/Streptomycin (PS). Vero and 293T GFP-split cells transduced cells

447   with pQCXIP were cultured with 4ug/ml and 1 ug/ml of puromycin (InvivoGen), respectively.

448   U2OS GFP-split cells transduced with pLenti6 were cultured in 1ug/ml puromycin and 10 ug/ml

449   blasticidin (InvivoGen). The MucilAir^{TM} primary human bronchial epithelial model was

450   previously described (Robinot *et al.*, 2021). All cells lines were either purchased from ATCC or

451   were kind donations from members of the Institut Pasteur and were routinely screened for

452   mycoplasma.

453

454   **Viruses**

455   The Wuhan SARS-CoV-2 strain (BetaCoV/France/IDF0372/2020) and the D614G strain (hCoV-

456   19/France/GE1973/2020) was supplied by Dr. S. van der Werf of the National Reference Centre

457   for Respiratory Viruses (Institut Pasteur, Paris, France). The D614G viral strain was sourced

458   through the European Virus Archive goes Global (EVAg) platform, which is funded by the

459   European Union's Horizon 2020 research and innovation program under grant agreement

460   653316. The Alpha strain was isolated in Tours, France, from an individual who returned from

461   the United Kingdom. The Beta strain (CNRT 202100078) originated from an individual in Creteil,

462   France). Informed consent was provided by the individuals for use of their biological materials.

463   The viruses were isolated from nasal swabs on Vero cells and further amplified one or two

464   passages on Vero cells. The viruses were sequenced directly from the nasal squabs and again

465   upon passaging. Titration of Viral stocks was performed by 50% tissue culture infectious dose

466   (TCID50).

467

468   **Viral Release**

469   For quantification of extracellular viral RNA, supernatants were diluted and heat-inactivated for

470   20min at 80°C. qRT-PCR was performed from 1µL of template RNA in a final volume of 5 µL per

471   reaction in 384-well plates using the Luna Universal Probe One-Step RT-qPCR Kit (New England

472   Biolabs) with SARS-CoV-2 N-specific primers (**EV Table 1)** on a QuantStudio 6 Flex

473   thermocycler (Applied Biosystems). Standard curve was performed in parallel using purified

474   SARS-CoV-2 viral RNA. Infectious virus release was assessed by harvesting supernatant at each

475   time point and preforming a TCID50 assay using Vero cells.

476

GFP-Split Fusion assay

477

478 For cell-cell fusion assays, Vero, U2OS-ACE2, or 293T cell lines stably expressing GFP1-10 and

479 GFP11 were co-cultured at a 1:1 ration ($3x10^4$, $2x10^4$ and $7x10^4$ cells/well total, respectively)

480 were transfected in suspension with a total of 100ng of DNA with Lipofectamine 2000 (Thermo)

481 in a 96 well plate (uClear, #655090). 10 ng of phCMV-SARS-CoV2-S and/or 25 ng of pCDNA3.1-

482 hACE2, 25 ng of pCSDest-TMPRSS2, and 40 ng of pQCXIP-IFITM were used and adjusted to 100

483 ng DNA with pQCXIP-Empty (control plasmid). At 20 h post-transfection images covering 80-

484 90% of the well surface, were acquired per well on an Opera Phenix High-Content Screening

485 System (PerkinElmer). The GFP area and the number of nuclei was quantified on Harmony High-

486 Content Imaging and Analysis Software **(Fig EV2B).** For infection, cells were plated at the

487 aforementioned concentrations and infected the next day with a range of MOIs and fixed at

488 20h (U2OS-ACE) or 48h (Vero) post-infection with 4% paraformaldehyde for 30mins. For video

489 microscopy experiments, Vero GFP split cells (mixed 1:1) were transfected in suspension with

490 50ng of phCMV-SARS-CoV2-S and 450ng of pQCXIP-Empty for 30mins at 37°C. Cells were

491 washed twice and then seeded at a confluency of $2x10^5$ cells per quadrant in a u-Dish 35mm

492 Quad dish (ibidi-#80416). Cells were allowed to settle, and fluorescence images were taken at

493 37°C every 10min up to 24h using a Nikon BioStation IMQ, with three fields for each condition.

494 Fusion defined as percent of GFP pixels was calculated with ImageJ.

495

Flow cytometry

496

26

497   For ACE2 binding, 293T cells transfected with S proteins for 24h were stained with soluble

498   biotinylated ACE2 diluted in MACS Buffer at indicated concentrations (from 60 to 0.01 µg/mL)

499   for 30 min at 4°C. The cells were then washed twice with PBS and then incubated with Alexa

500   Fluor 647- conjugated-streptavidin (Thermo Fisher Scientific, 1:400) for 30 min at 4°C. Finally,

501   the cells were washed twice with PBS and then fixed with 4% paraformaldehyde. The results

502   were acquired using an Attune Nxt Flow Cytometer (Life Technologies). Transfection efficiency

503   was assessed by staining with pan-SARS-CoV-2 human mAb129. Antibody binding to S proteins

504   was assessed via s analogous protocol where transfected 293T cells were first stained with

505   either human mAb10 (pan-coronavirus anti-S2), mAb102 and mAb129 (pan-SARS-CoV-2),

506   mAb48 and mAb98 (SARS-CoV-2 anti-RBD), and mAb71 (SARS-CoV-2 anti-NTD) at 1 µg/mL. The

507   antibodies were derived from convalescent individuals by the Mouquet lab at the Institut

508   Pasteur. mAb10 was generated during the early stages of the epidemic from a patient infected

509   with the Wuhan strain and thus has a higher affinity for the Wuhan spike (Planas *et al.*, 2021a).

510   For viral replication, infected cells were fixed at each time with 4% paraformaldehyde for 30

511   mins. The cells were stained in the same manner described above with anti-spike mAb102 and

512   secondary Alexa Fluor 647 (1:500) in MACS buffer containing 0.05% saponin. The gating

513   strategy to determine spike positive cells is represented in the supplement **(Fig EV1B)**.

514   **Western Blot**

515   Cells were lysed in TXNE buffer (1% Triton X-100, 50 mM Tris–HCl (pH 7.4), 150 mM NaCl, 5 mM

516   EDTA, protease inhibitors) for 30 min on ice. Equal amounts (20–50 µg) of cell lysates were

517   analyzed by Western blot. The following antibodies were diluted in WB-buffer (PBS, 1% BSA,

27

518   0.05% Tween, 0.01% Na Azide): rabbit anti-human TMPRSS2 (Atlas antibodies cat# HPA035787,

519   1:1,000), rabbit anti-human actin (Sigma cat#A2066, 1:2,000), and human anti-S Serum derived

520   from a convalescent individual (1:1000). Species-specific secondary DyLight-coupled antibodies

521   were used (diluted 1:10,000 in WB-buffer) and proteins revealed using a Licor Imager. Images

522   were quantified and processed using Image Studio Lite software.

523

524

525   **Statistical analysis**

526   Flow cytometry data was analyzed with FlowJo v10 software (Tristar). Calculations were all

527   performed with Microsoft Excel 365. GraphPad Prism 9 was used to generate figures and for

528   statistical analysis. Statistical significance between different conditions was calculated using the

529   tests indicated in the corresponding figure legends.

589   post transfection, normalized to D614G. Scale bars: 200 μm. Data are mean ± SD of at least 3

590   independent experiments. Statistical analysis: One-way ANOVA compared to D614G reference,

591   ns: non-significant, *P < 0. 05, **P < 0.01, ***P < 0.001, ****P < 0.0001.

592

593   **Figure 4. Mutations associated with Alpha and Beta S proteins differentially affect cell-cell**

594   **fusion. (A)** Schematic representation of the S protein colour coded for the functional regions:

595   N-terminal domain (NTD), receptor binding domain (RBD), fusion peptide (FP), heptad repeat

596   1,2 (HR1, HR2), transmembrane anchor (TA), C-terminal domain (CTD). **(B) Left Panel:** Vero

32

597 GFP-split cells were transfected with spike plasmids containing each of the individual mutations

598 associated with Alpha variant in the D614G background. The amount of fusion was quantified at

599 20h and normalized to D614G reference plasmid. Colour code of each mutation corresponds to

600 spike functional regions represented in (A). **Right Panel:** Quantified fusion for each of the

601 individual spike mutations associated with Beta. Data set for N501Y and D614G reference

602 mutations are duplicated between left and right panels for presentation as mutations are

603 common to both variants. **(C) Left Panel:** Quantified fusion of the Alpha + E484K variant S

604 protein normalized to D614G S. **Right Panel:** Representative images of fusion at 20h. Scale bar:

605 200 μm. Data are mean ± SD of at least 4 independent experiments. Top and bottom are the

606 same images with and without Hoechst channel. Statistical analysis: statistics for both left and

607 right panels of A were conducted together. One-way ANOVA compared to D614G reference, ns:

608 non-significant, *P < 0. 05, **P < 0.01, ***P < 0.001, ****P < 0.0001.

609

610 **Figure 5. ACE2 and monoclonal antibody binding to S proteins with Alpha and Beta associated**

611 **mutations. (A)** 293T cells were transfected S proteins with each variant-associated mutation for

612 24h and stained with biotinylated ACE2 and fluorescent streptavidin before analysis by flow

613 cytometry. **(B) Left Panel:** EC50 values (concentration of ACE2 needed for 50% binding) for

614 Alpha and associated mutations. Colour code corresponds to location on spike functional

615 domains and lower EC50 values signifies higher affinity to ACE2 binding. **Right Panel:** EC50

616 values for Beta and associated mutations. Data set for N501Y and D614G reference mutations

617 are duplicated between left and right panels as mutations are common to both variants. **(C)**

33

618   Spike transfected 293T cells were stained with human monoclonal antibodies targeting the S2

619   (mAb10), RBD (mAb48 and mAb98), and the NTD (mAb71). Cells were analyzed by flow

620   cytometry. The percentage of positive cells is indicated. Data are mean of at least 3

621   independent experiments. Statistical analysis: One-way ANOVA compared to D614G reference,

622   ns: non-significant, *P < 0. 05, **P < 0.01, ***P < 0.001, ****P < 0.0001.

623   **Figure 6. Delta SARS-CoV-2 S protein induces more syncytia formation and binds more to**

624   **ACE2 than D614G. (A)** Vero GFP-split cells were transfected with variant S proteins and imaged

625   18h post-transfection. **Left Panel**: Fusion was quantified by GFP area/ number of nuclei and

626   normalized to D614G for each of the transfected variant spike proteins. **Right Panel**:

627   Representative images of Vero GFP-split cells 18h post-transfection, GFP (Green) and Hoechst

628   (Blue). Top and bottom are the same images with and without Hoechst channel. **(B) Left Panel**:

629   Quantification of Delta S protein mediated fusion in Vero-GFP split cells by video microscopy.

630   Results are mean ± SD from three fields per condition from one representative experiment.

631   **Right Panel**: Fusion quantification of 3 independent video microscopy experiments, 20h post

632   transfection, normalized to D614G. **(C) 293**T cells were transfected S proteins with each variant-

633   associated mutation for 24h and stained with biotinylated ACE2 and fluorescent streptavidin

634   before analysis by flow cytometry. **Left Panel:** Representative ACE2 binding dilution curves for

635   the Delta variant in relation to Alpha and D614G. **Right Panel:** EC50 values (concentration of

636   ACE2 needed for 50% binding) for Alpha for the Delta variant. Scale bars: 200 µm. Data are

637   mean ± SD of at least 3 independent experiments. Statistical analysis: One-way ANOVA

638   compared to D614G reference, ns: non-significant, *P < 0. 05, **P < 0.01, ***P < 0.001, ****P <

639   0.0001.

640

641

642   **Figure EV1. Assessment of viral replication by flow cytometry in cell lines (A)** Caco-2/TC7

643   (left), Calu-3 (middle), and Vero cells (right) were infected at the indicated MOIs with SARS-CoV-

644   2 variants for 24h. The number of spike protein positive cells was determined by flow

645   cytometry upon staining with human pan-SARS-CoV-2 mAb102. Only MOIs that were not

646   saturating were used to generate replication curves for each cell line studied. **(B)**

647   Representative image of gating strategy used for flow cytometry to determine spike positive

648   cells.

649

650   **Figure EV2. Qualitative and quantitative assessment of syncytia formation**

651   **(A)** U2OS-ACE2 GFP-split cells were infected at MOI 0.01 with the Wuhan, D614G, Alpha and

652   Beta strains for 20h. Cells were stained for spike protein with the human pan-SARS-CoV-2 102

653   mAb and Alex647 fluorescent secondary antibody. Representative confocal images of the

654   variant induced syncytia formation: GFP-Split (Green), Spike (red) and Hoechst (Blue). **(B)**

655   Quantification method for syncytia formation using the Opera Phenix high content imager and

656   harmony software: Total syncytia area (GFP area) is normalized for cell number upon

657   quantifying the number of nuclei (Hoechst). Scale bars: 50 µm

658

659   **Figure EV3. Syncytia formation by SARS-CoV-2 variants (A) Left Panel:** Fusion normalized to

660   D614G for U2OS-ACE2 20h post infection at MOI 0.01. **Right Panel:** Representative images of

661   U2OS-ACE2 20h post infection, GFP (Green) and Hoechst (Blue). Top and bottom are the same

662   images with and without Hoechst channel. **(B) Left Panel:** Quantified fusion of Vero cells

663   infected at MOI 0.1. **Right Panel:** Representative images of Vero cells 48h post infection. Scale

664   bars: 200 µm. Data are mean ± SD of at least 3 independent experiments. Statistical analysis:

665   One-way ANOVA compared to D614G reference, ns: non-significant, *P < 0. 05, **P < 0.01,

666   ***P < 0.001, ****P < 0.0001.

667   **Figure EV4. SARS-CoV-2 variant S proteins are expressed equally at the cell surface.** 293T cells

668   were transfected with variant S proteins for 20h and stained with human pan-coronavirus

669   mAb10 without permeabilization. 293T cells were chosen because they lack ACE2 and do not

670   fuse upon S transfection; this makes them suitable for single cell flow cytometry **(A) Left Panel:**

671   Quantification of percent of cells expressing each spike at the surface. **Right Panel:**

672   Representative FACs plots. **(B)** Quantification of median florescent intensity (MFI) of variant

673   spikes at the cell surface and representative histograms of MFI of the Wuhan, D614G, Alpha,

674   Beta, and Alpha + E484K variants spikes using mAb10. **(C)** Quantification of median florescent

675   intensity (MFI) of variant spikes at the cell surface and representative histograms of MFI of the

676   Wuhan, D614G, Alpha, Beta, and Alpha + E484K variants spikes using mAb129. **(D)**

36

677   Quantification of median florescent intensity (MFI) of variant spikes at the cell surface and

678   representative histograms of MFI of the Delta variant compared to the Alpha and D614G using

679   mAb129. **(E)** Comparison of the impact of TMPRSS2 on variant S protein processing measured

680   by western blot. Plasmids encoding for S protein were co-transfected with or without plasmids

681   expressing TMPRSS2 in 293T cells for 24h. Representative image of 2 experiments. Flow

682   cytometry data are mean ± SD of at least 3 independent experiments. Statistical analysis: One-

683   way ANOVA compared to D614G reference, ns: non-significant, $*P < 0.05$, $**P < 0.01$, $***P <$

684   0.001, $****P < 0.0001$.

685

686   **Figure EV5. Impact of IFN-$\beta1$ and IFITMs on SARS-CoV-2 variant replication and S protein**

687   **mediated cell-cell fusion.**

688   **(A)** Vero cells were pre-treated for 2h with a serial dilution of IFN-$\beta1$ prior to infection with the

689   SARS-CoV-2 variants. Infected cells were maintained in media containing IFN-$\beta1$ and analyzed

690   by flow cytometry 48h post-infection to determine relative infection change. **(B)** U20S-ACE2

691   GFP split cells were pre-treated for 2h with a serial dilution of IFN-$\beta1$ prior to infection with the

692   SARS-CoV-2 variants. Infected cells were maintained in media containing IFN-$\beta1$ and relative

693   inhibition of syncytia formation 20h post-infection was determined via GFP signal. **(C)** A co-

694   culture of 293T GFP-Split cells were transfected with combination of S, control, ACE2, TMPRSS2

695   and IFITM plasmids and then imaged 18h post-transfection. Effect of IFITMs and TMPRSS2 on

696   the cell-cell fusion induced by different spike proteins **(D)** Wuhan **(E)** D614G **(F)** Alpha **(G)** Beta.

37

697   Data are mean ± SD of at least 3 independent experiments. Statistical analysis: One-way ANOVA

698   compared to D614G reference or control plasmid transfection, ns: non-significant, *P < 0. 05,

699   **P < 0.01, ***P < 0.001, ****P < 0.0001.

700   **Figure EV6. SARS-CoV-2 variant S protein associated mutations are expressed equally at the**

701   **cell surface.** 293T cells were transfected with S proteins with each of the variant associated

702   mutations for 18h and stained with human pan-coronavirus mAb10 without permeabilization.

703   **(A)** Representative FACs plots of percent of cells expressing each mutant spike at the surface.

704   **(B)** Quantification of percent of cells expressing each spike at the surface. **(C)** Quantification of

705   median florescent intensity (MFI) of the mutant spikes at the cell surface. **(D)** Representative

706   histograms of MFI of each mutant spike. **(E)** Representative images of Vero GFP split cells 20h

707   after transfection with each Alpha variant associated mutant spike, GFP-Split (Green). **(F)**

708   Representative images of Vero GFP split cells 20h after transfection with each Beta variant

709   associated mutant spike. Statistical analysis: One-way ANOVA compared to D614G reference,

710   ns: non-significant, *P < 0. 05, **P < 0.01, ***P < 0.001, ****P < 0.0001.

711

712   **Figure EV7. ACE2 binding curves to SARS-CoV-2 variant S proteins and associated mutations.**

713   293T cells were transfected with variant or mutant spike proteins for 24h and stained with a

714   serial dilution of soluble biotinylated ACE2 and revealed by fluorescent streptavidin before

715   analysis by flow cytometry. **(A)** ACE2 binding dilution curves of each variant spike. **(B)** ACE2

716   binding dilution curves of each variant associated mutation located in spike n-terminal domain

38

717   (NTD) **(C)** receptor binding domain (RBD) **(D)** S1/S2 cleavage site **(E)** heptad repeat 1-2 site

718   (HR1-HR2). Data are mean ± SD of 3 independent experiments.

719

720   **Movie EV1: Alpha (B.1.1.7) and Beta (B.1.351) S proteins induce more robust syncytia**

721   **formation than D614G or Wuhan**

722   A co-culture of Vero GFP-split cells were transfected with plasmids expressing each of the

723   variant spike proteins and imaged by video microscopy at a rate of 6 images per hour for 24h.

724   GFP signal is superimposed over BF images. The white border represents the GFP area

725   calculated by the ImageJ macro in order to quantify fusion. **Top left:** Wuhan S **Top right:** D614G

726   S **Bottom Left:** Alpha (B.1.1.7) S **Bottom right:** Beta (B.1.351) S. One representative field for

727   each condition is shown.
