19

20   **One-sentence summary:** DNE1, a NYN domain protein interacts with the decapping activator

21   DCP1 and, together with DCP2, specify phyllotactic patterns in *Arabidopsis*.

22

23   **ABSTRACT**

24   In eukaryotes, general mRNA decay requires the decapping complex. The activity of this complex

25   depends on its catalytic subunit, DCP2 and its interaction with decapping enhancers, including its

26   main partner DCP1. Here, we report that in *Arabidopsis*, DCP1 also interacts with a NYN domain

27   endoribonuclease, hence named DCP1-ASSOCIATED NYN ENDORIBONUCLEASE 1 (DNE1).

28   Interestingly, we find DNE1 predominantly associated with DCP1 but not with DCP2 and reciprocally,

29   suggesting the existence of two distinct protein complexes. We also show that the catalytic residues of

30   DNE1 are required to repress the expression of mRNAs *in planta* upon transient expression. The

31   overexpression of DNE1 in transgenic lines leads to growth defects and transcriptomic changes

32   related to the one observed upon inactivation of the decapping complex. Finally, the combination of

33   *dne1* and *dcp2* mutations, revealed a functional redundancy between DNE1 and DCP2 in controlling

34   phyllotactic pattern formation in *Arabidopsis*. Our work identifies DNE1, a hitherto unknown DCP1

35   protein partner highly conserved in the plant kingdom and identifies its importance for developmental

36   robustness.

37

38   **INTRODUCTION**

39   Messenger RNA (mRNA) decay is crucial for the regulation of gene expression and is required for
40   stress response and developmental transitions. Most mRNAs are degraded by the 5'-3' pathway which
41   requires decapping of mRNA (Sorenson et al., 2018; Tuck et al., 2020). mRNA decapping is a highly
42   conserved mechanism in eukaryotes and consists in the hydrolysis of the 5' m7G cap structure of the
43   mRNA. Decapping produces an unprotected 5' phosphate extremity, rapidly attacked by the cytosolic
44   5'-3' exoribonuclease, XRN1 in mammals and XRN4 in plants. The catalytic subunit of the decapping
45   complex is the Nudix hydrolase DCP2, which requires interactions with enhancers of decapping to
46   switch from its inactive to its active form (Chang et al., 2014; Wurm and Sprangers, 2019). These
47   activators notably include DCP1, LSM14A, EDC4, PAT1, the LSm1-7 complex and the DDX6 RNA
48   helicases in metazoans (She et al., 2008; Arribas-Layton et al., 2013). mRNA decapping represents a
49   limiting step of many cellular RNA decay pathways. Decapping notably operates after mRNA
50   deadenylation (Couttet et al., 1997), downstream of the action of microRNAs (Nishihara et al., 2013),
51   on mRNAs containing premature termination codons, through the action of Nonsense Mediated Decay
52   (Lejeune et al., 2003), as well as on mRNAs with specific stem-loop structures in their UTRs in
53   Staufen Mediated Decay (Kim and Maquat, 2019).

54   In plants, decapping has been mainly studied in *Arabidopsis thaliana*, whose genome encodes
55   orthologs of DCP2, DCP1, LSM14A called DECAPPING 5 (DCP5), three DDX6-like RNA helicases
56   called RH6, RH8 and RH12 as well as an ortholog of EDC4 called VARICOSE (VCS) and its
57   presumed inactive homolog VARICOSE RELATED (VCR) (Deyholos et al., 2003; Xu et al., 2006; Xu
58   and Chua, 2009; Chantarachot et al., 2020). Null mutants of *DCP1*, *DCP2*, *DCP5* and *VCS* show
59   defects in the formation of the vasculature of embryonic leaves and are seedling lethal (Deyholos et al.,
60   2003; Xu et al., 2006). A recent transcriptome-wide decay rate analysis in *Arabidopsis* revealed the
61   major role of VCS in mRNA decay, with VCS involved in the decay of 68% of mRNAs (Sorenson et al.,
62   2018). Although the importance of components of the decapping machinery was clearly established
63   for its role in plant growth, biotic and abiotic stress response, only very limited information about the
64   corresponding protein complexes was gathered to date (Xu and Chua, 2012; Soma et al., 2017; Yu et
65   al., 2019; Kawa et al., 2020). The only data were obtained early on by *in vitro* tests and/or transient
66   expression strategies, but in contrast to other organisms, was not yet approached by unbiased
67   strategies designed to study protein complexes *in vivo*. Fundamental differences in the composition of
68   this complex in the plant kingdom, including the existence of plant specific partners could thus not be
69   assessed.

70   In this work, we used an unbiased approach coupling immunoprecipitations (IPs) and mass
71   spectrometry to define the interactome of the decapping activator DCP1 and the decapping enzyme
72   DCP2. In addition to characterize the *Arabidopsis* decapping complex, our work identifies a NYN
73   domain endoribonuclease as a direct protein partner of the decapping activator DCP1, therefore
74   named DCP1-ASSOCIATED NYN ENDORIBONUCLEASE 1 (DNE1). The closest homologue of
75   DNE1 in mammals is Meiosis regulator and mRNA stability factor 1 (MARF1), a NYN domain
76   endoribonuclease necessary for meiosis progression and retrotransposon surveillance in oocytes (Su
77   et al., 2012a; Su et al., 2012b; Nishimura et al., 2018). MARF1 is associated to the core decapping
78   complex formed by DCP1, DCP2 and EDC4 (Bloch et al., 2014). In contrast, we show here data

79 suggesting the preferential association of DNE1 with DCP1 over DCP2. A phylogenetic analysis
80 indicates that DNE1 is a highly conserved NYN domain protein in streptophytes and is likely an active
81 enzyme as its catalytic residues are required to repress mRNAs upon transient expression.
82 Furthermore, using a transcriptomic approach, we identified that overexpression of DNE1 leads to
83 transcriptomic changes showing similarities with the ones observed upon inactivation of decapping.
84 Finally, we identified that phyllotactic defects appear in *dne1 dcp2* double mutants demonstrating the
85 redundant functions of DNE1 and DCP2 in developmental robustness.

86

87 **RESULTS**

88

89 **Identification of proteins associated with the decapping complex in *Arabidopsis***

90 To determine the composition of the decapping complex in *Arabidopsis*, we used an unbiased
91 proteomic approach. This approach is based on IP experiments coupled to mass spectrometry
92 analysis using transgenic lines expressing either a functional yellow fluorescent protein (YFP) fusion of
93 DCP1 expressed under its endogenous promoter or a functional version of DCP2 expressed under the
94 35S CaMV promoter (Goeres et al., 2007). Both IPs were efficient and provided access to both DCP1
95 and DCP2 enriched extracts (Fig. 1A, Supplementary Table S1). These extracts were then analyzed
96 by liquid chromatography coupled to tandem mass spectrometry (nanoLC-MS/MS). Wild-type non-
97 transgenic plants were used as controls for the enrichment analysis. This strategy allowed the
98 identification of 15 proteins significantly enriched with DCP1 (Fig. 1B, Supplementary Table S2) and 8
99 proteins significantly enriched with DCP2 (Fig. 1C, Supplementary Table S3). The most enriched
100 protein found with both DCP1 and DCP2 is VCS, which validates our approach. Of note, we also
101 observed a strong enrichment of VCR, previously proposed not to be involved in decapping (Xu et al.,
102 2006). Specifically enriched with DCP1, we found the DDX6-like RNA helicases RH6, RH8 and RH12,
103 known to contact the decapping complex in mammals (Ayache et al., 2015) and that we recently found
104 to co-purify with DCP5 and with the key player of NMD UPF1 (Chicois et al., 2018). An RNA helicase
105 of the DDX3 family, RH52, in addition to 9 other proteins of unknown functions in RNA degradation
106 was also specifically enriched. Among these factors, our attention was particularly drawn by a putative
107 endonuclease (AT2G15560), enriched in DCP1, but not present in DCP2 IPs. We knew from our
108 previous work on UPF1 interactome, that this protein also co-purified with both UPF1 and DCP5, and
109 colocalized with UPF1 in cytoplasmic foci (Chicois et al., 2018). Because this predicted endonuclease
110 was repeatedly found associated with RNA decay factors, we sought to further characterize its
111 interactome, its influence on the transcriptome and its function in *Arabidopsis*. Based on the results
112 presented hereafter, this protein was named DCP1-ASSOCIATED NYN ENDORIBONUCLEASE 1
113 (DNE1).

114

115 **DNE1 directly interacts with DCP1**

116 Transcriptomic data indicated that DNE1 is broadly expressed during plant development together with
117 DCP1 and DCP2, albeit often at lower levels (Supplementary Fig. S1). As a first step in DNE1

3

118   characterization, we determined its interactome by IPs coupled to LC-MS/MS analysis. Previously
119   designed transgenic lines expressing the endonuclease fused to GFP (Chicois et al., 2018) were used
120   to perform DNE1 IPs (Fig. 2A). Four factors known to be associated with the decapping complex were
121   among the proteins significantly enriched in DNE1 IPs: DCP1, VCS, VCR and UPF1 (Fig. 2B,
122   Supplementary Table S4). Interestingly, DCP1 was the most enriched protein in DNE1 IPs.
123   Considering that DNE1 was also among top partners in DCP1 IPs, we tested for a possible direct
124   interaction between DCP1 and DNE1 by yeast two hybrid (Y2H) assays. Indeed, yeast expressing
125   both DCP1 and DNE1 showed fully restored growth on selective yeast media (Fig. 2C). Growth of the
126   Y2H strain was also restored by co-expressing DCP1 and a version of DNE1 mutated in a predicted
127   catalytic residue (D153N), suggesting that this interaction is independent of its catalytic activity.
128   To our surprise, DCP2 was not significantly enriched in neither DNE1 (Fig. 2B) nor DCP1 IPs (Fig. 1B),
129   and only a few mRNA decapping proteins were present in the DCP2 IPs (Fig. 1C). To test if the non-
130   detection of DCP2 with DCP1 and the low efficiency of the DCP2 IPs can be solved by stabilizing
131   transient or weak interactions, DCP1, DCP2 and DNE1 IPs were repeated with formaldehyde
132   crosslinked protein extracts. In these conditions, we observed the association between DCP1 and
133   DCP2 in both DCP1 and DCP2 IPs (Fig. 3A, 3B; Supplementary Tables S5, S6). In addition, we also
134   found additional co-purifying partners linked to decapping in DCP2 IPs (including DCP1, RH6, RH8,
135   RH12, UPF1 and PAT1, Fig. 3B; Supplementary Tables S6). Interestingly, DNE1 was only detected
136   together with DCP1 but was again absent from DCP2 purifications (Fig. 3). In contrast, DCP1 was
137   found together with both DCP2 and DNE1 (Fig. 3B, 3C; Supplementary Tables S6, S7). These data
138   obtained upon crosslinking solve the initial low efficiency of DCP2 IPs. Although no definitive
139   conclusions can be drawn from negative results in IP experiments, these data taken together are
140   coherent with the existence of two different complexes, one comprising DCP1-DCP2 and one
141   containing DCP1-DNE1.
142
143   **DNE1 is a component of P-bodies**

144   Our previous work localized DNE1 in cytoplasmic foci with UPF1 upon transient expression, identifying
145   DNE1 as a putative novel component of P-bodies (Chicois et al., 2018). To further validate this
146   localization of DNE1 in P-bodies, we produced transgenic *Arabidopsis* lines expressing DNE1 (fused
147   either to GFP or RFP) together with archetypal markers of either stress granules (PAB2-RFP) or P-
148   bodies (YFP-DCP1, UPF1-RFP). In these lines, DNE1 did not colocalize with PAB2, both in the
149   absence of stress, when PAB2 exhibits a diffuse localization (Pearson correlation coefficient 0.18, Fig.
150   4) and under heat stress, when PAB2 is relocated in stress granules (Pearson correlation coefficient
151   0.35; Fig. 4). By contrast, DNE1 perfectly colocalized with its protein partner DCP1 and with UPF1 in
152   P-bodies (Pearson correlation coefficient 0.9, Fig. 4). We therefore concluded that DNE1 is a *bona*
153   *fide* component of P-bodies in *Arabidopsis*.
154
155   **DNE1 is a well conserved NYN domain protein in streptophytes and composed of three**
156   **domains**

4

157 To determine the evolutionary conservation of DNE1, we looked for orthologues of the *Arabidopsis*
158 DNE1 protein in major plant lineages (rhodophytes, chlorophytes and streptophytes). We refined the
159 results based on the presence of the structural domains found in *Arabidopsis* DNE1 that are one NYN
160 domain and two consecutive OST-HTH domains. We found clear orthologues of DNE1 in basal
161 streptophytes algae, mosses, ferns, gymnosperms and all flowering plants (Fig. 5A). We could not find
162 NYN domains associated with predicted OST-HTH domains in the rhodophytes and chlorophytes
163 phyla. However, we do not exclude the hypothesis that OST-HTH sequences could be more
164 degenerated from the consensus in these lineages and therefore not recognized by the prediction
165 software. Indeed, the sequence of NYN domain is more conserved (identity and similarity) than the
166 OST-HTH domains in the streptophytes, especially the second OST-HTH (Supplementary Table S8).
167 Of note, the second OST-HTH domain was not found in *Klebsormidium* a basal streptophytes alga but
168 KfDNE1 was the most related enzyme to AtDNE1 in this specie. Overall, DNE1 is conserved in most if
169 not all species of the streptophyte lineage indicating that its main function in plants is likely under
170 selection pressure.
171 The typical structure of DNE1 is characterized by the presence of a NYN domain in the N-terminal part
172 of the protein and of two OST-HTH domains in the C-terminal part (Fig. 5B). The length between the
173 NYN domain and the two OST-HTH domains is variable with a larger region in early divergent species
174 compared to more recent species (Fig. 5B). The most compact enzymes are found in the
175 Brassicaceae (*Arabidopsis* family) with proteins whose sizes are under 500 amino-acids compared to
176 600 aa in average for conifers and more than 700 aa in *Klebsormidium*. The alignment of the NYN and
177 the OST-HTH1 domains shows that the catalytic domain is extremely conserved at the amino acid
178 level, feature supported by the identity and similarity chart (Supplementary Table S8) while the RNA
179 binding domains are slightly less conserved (Fig. 5C, 5D, Supplementary Table S8). Importantly, we
180 identified the three aspartic acid residues known to be necessary for the enzymatic activity of NYN
181 domains (Fig. 5C, 5E). These residues are strictly conserved in all plant species assessed (Fig. 5C).
182 The closest homologue of DNE1 in mammals is the endoribonuclease MARF1. In mammals, MARF1
183 functions in female germlines where it is crucial for meiosis and defenses against damages caused by
184 retrotransposons to the oocyte's genome (Su et al., 2012a; Su et al., 2012b). The tridimensional
185 structure predictions of DNE1 protein domains fit well into the known tridimensional crystal structures
186 of MARF1 domains, both for the NYN (Fig. 5E) and for the OST-HTH (Fig. 5F) domains. In addition,
187 the conserved Asp catalytic residues (in orange Fig. 5E) share a similar location in the structural
188 alignment of MARF1 and DNE1 NYN domains that strongly suggests that DNE1 is also an active
189 enzyme. This possibility was supported by *in vivo* transient expression experiments of WT or a
190 catalytic mutant of DNE1 (D153N) in *N. benthamiana*. In this experiment either RFP-DNE1 or RFP-
191 DNE1^{D153N} catalytic mutant was co-expressed with a reporter *GFP* mRNA in *N. benthamiana* leaves. A
192 dramatic drop in the accumulation of the co-expressed *GFP* mRNA and three endogenous mRNAs
193 was observed for three independent replicates 2.5 days after leaf infiltration of only RFP-DNE1 but not
194 RFP-DNE1^{D153N} (Fig. 6). Of note, this difference is not due to a lower expression of the DNE1-D153N
195 mutant as RFP-DNE1-D153N accumulates to higher levels that RFP-DNE1 in this experimental setup
196 (Supplementary Fig. S2). This result indicates that the transient expression of DNE1 represses the

197 accumulation of mRNAs and that this repression requires a wild-type NYN domain, supporting that
198 DNE1 is an active NYN domain enzyme.

199

DNE1 overexpression perturbs plant growth and show similar changes in gene expression than decapping mutants

202 To analyze the influence of DNE1 on the transcriptome, we tested the impact of the deregulation of
203 DNE1 on *Arabidopsis* transcriptome using RNA-seq. For this purpose, we used three different genetic
204 backgrounds: an insertion mutant (*dne1-1*), which harbors a T-DNA insertion within the *DNE1* coding
205 sequence, and transgenic lines overexpressing protein fusions with GFP of either a WT (DNE1 OE) or
206 a DNE1 point mutant (D153N OE) in *dne1-1* background. The point mutation is in a codon coding for a
207 conserved aspartic acid residue and predicted to abolish the catalytic activity of DNE1. Visual
208 inspections made during the growth of *dne1-1* mutant seedlings did not reveal any morphological
209 defects. In contrast, the overexpressing lines of both DNE1 and D153N both showed growth
210 retardation (Fig. 7A, Supplementary Fig. S3 and S4). We selected homozygous lines expressing
211 DNE1 and D153N. Of note, we used a D153N OE line expressing lower protein levels than the wild-
212 type DNE1 OE lines (Fig. 7B) as D153N lines with stronger protein expression could not be
213 propagated. We analyzed the transcriptome of these lines and compared them with the transcriptome
214 of wild-type plants and the null decapping mutant *vcs-6*. The global differences in gene expression
215 were visualized on a histogram (Fig. 7C). Very little variation in gene expression was observed in
216 *dne1-1*, with only 8 significantly deregulated genes. In contrast, DNE1 OE and D153N OE lines
217 showed substantial transcriptome changes, while as expected massive deregulations occurred in *vcs-*
218 *6*. Both DNE1 OE and D153N OE lines showed similar gene deregulation trend with more upregulated
219 than downregulated transcripts. Indeed, we observed that 93% and 77% of the significantly
220 deregulated transcripts were upregulated in WDNE1 OE and D153N OE, respectively. This result
221 suggests that the overexpression of wild-type or mutant DNE1 might have similar effect and that this
222 effect is likely not solely due to catalytic activity. Importantly, D153N expression affected more broadly
223 the transcriptome than the expression of DNE1, with *ca* ten times more deregulated genes in D153N
224 compared to DNE1. We found 64 commonly upregulated genes in DNE1 OE and D153N OE (Fig.
225 7D). The significance of the overlap between DNE1 OE and D153N OE deregulated genes was tested
226 using a hypergeometric test. With P-values of 4.6×10^{-42} for upregulated genes and 4.1×10^{-7} for
227 downregulated genes, this result indicates a similar signature of transcriptomic changes in DNE1 and
228 D153N (Table S9).
229 We then tested whether gene deregulation in DNE1 and D153N OE lines was related to genes
230 deregulated upon inactivation of decapping. We thus compared the list of genes deregulated in the
231 two DNE1 OE lines with those deregulated in the null decapping mutant *vcs-6*. Strikingly we observed
232 a significant overlap of genes upregulated in *vcs-6* and genes upregulated either in DNE1 OE or in
233 D153N OE (P-values: DNE1 = 4.9×10^{-66}, D153N = 2.8×10^{-307}): 70% (132/188) and 63% (693/1103)
234 of genes upregulated in DNE1 OE or in D153N OE respectively, are also up regulated in *vcs-6* (Fig.
235 7D left panel, Table S9). In contrast, and as a negative control, the comparison *vcs* downregulated
236 versus DNE1 OE or D153N OE upregulated, gave no significant overlap with p-values of 1 (Fig. 7D

237   right panel, Table S9). These results were validated by a Q-PCR experiment for a selection of 19

238   targets with different profiles (Supplementary Fig. S5, Supplementary Table S10). This assay validates

239   our global analysis with a different experimental setup and strengthen the previous observations.

240   Among the 13 genes validated as upregulated in DNE1 OE and/or in D153N OE tested, 11 loci were

241   validated to be also upregulated in *vcs-6*, reinforcing the link between the overexpression of DNE1

242   and the effect of a mutation in VCS. In this analysis, 9 out of 13 upregulated genes were found more

243   deregulated in D153N than DNE1, confirming the stronger effect of D153N expression compared to

244   DNE1. Collectively those results indicate that overexpression of DNE1 altered gene expression in a

245   manner reminiscent of *vcs* mutant plants, suggesting that DNE1, when overexpressed, alters the

246   action of the decapping complex.

247

248   **Altering DNE1 expression or DCP2 action affects similar loci**

249   As VCS is associated with DCP1, DCP2 and DNE1, and in order to test a possible functional link

250   between the decapping enzyme DCP2 and DNE1, we then compared transcriptomic data obtained by

251   microarray for *tdt-1,* a previously reported *dcp2* allele (Goeres et al., 2007), with our RNA-seq data of

252   *vcs-6* and D153N OE. As expected, a significant overlap was found between the *vcs* and the *dcp2*

253   upregulated genes (P-value 2.1 x 10^{-37}) with 67.8% of genes upregulated in *dcp2* also upregulated in

254   *vcs* (98/142, Fig. 7F). Interestingly, there was also a significant overlap of genes upregulated in

255   *dcp2* and D153N (P-value of 3.1 x 10^{-48}) with 37% of genes upregulated in *dcp2* also upregulated

256   in D153N upregulated genes (53/142; Fig. 7F). Altogether, these analyses indicate a strong

257   functional links between DNE1, VCS and DCP2. This comparison shows that the overexpression of

258   D153N has perturbed the accumulation of a set of mRNAs also affected by mutation in *DCP2*. In

259   support of this observation, we tested if mRNAs deregulated in D153N OE are enriched in targets of

260   the decapping complex. We thus compared our RNA seq data for D153N OE and *vcs* with degradome

261   sequencing data obtained by GMUCT (Anderson et al., 2018), a sequencing protocol which quantifies

262   the accumulation of uncapped transcripts. Strikingly, in this comparison, only the upregulated genes in

263   *vcs* and DNE1 D153N OE were enriched in loci accumulating uncapped transcripts (Fig. 7G). This

264   results further strengthen our previous conclusion and validate that the deregulations observed in

265   D153N OE seems to preferentially affect targets of the decapping complex.

266

267   **Mutations in DNE1 affect the robustness of phyllotaxis when DCP2 function is altered**

268   To investigate the functional link between DNE1 and DCP2, we produced double mutants between

269   *its1*, a weak allele of *dcp2* mutated in its catalytic domain (called *dcp2^its1* thereafter) and two *dne1*

270   point mutants generated by CRISPR/Cas9 (*dne1-2* and *dne1-3,* Supplementary Table S11). The

271   *dne1-3* mutant contains a 39 nt insertion leading a premature termination codon early in *DNE1* NYN

272   domain, whereas *dne1-2* contains a 21nt in frame deletion at position 193, which predicts the

273   production of a DNE1 protein with a 7 amino acids (aa) deletion in the catalytic domain. Neither the

274   weak *dcp2^its1* mutant, nor the *dne1-2* and *dne1-3* showed any obvious morphological defects. In

275   contrast, *dne1 dcp2^its1* double mutants showed defects in the maintenance of the phyllotactic pattern

276   produced by the floral meristem (Fig. 8A). We quantified this defect by measuring divergent angles
277   between successive siliques on the main stem (Fig. 8B). Overall, we made measurements for
278   between 30 to 40 plants per genotype in three to four biological replicates, and measured divergent
279   angles between 35 siliques per plant on the main stem. These measures clearly show an increased
280   proportion of non-canonical divergent angles occurring specifically and reproducibly in *dne1 dcp2^{its1}*
281   double mutants and not in *dcp2^{its1}* and *dne1* single mutants compared to WT. The defects observed in
282   the double mutants were confirmed by the analysis of the divergent angles distribution using the
283   Kolmogorov-Smirnov test, with p-values showing significant difference from the WT for *dcp2^{its1} dne1-3*
284   (P-value 6.5×10^{-8}) and *dcp2^{its1} dne1-2* (P-value 2.2×10^{-16}, Fig. 8B, Table S12). These defects also
285   appeared reproducibly on every biological replicate, when analyzed separately (Supplementary Fig.
286   S6). This analysis demonstrates the synergistic effect of *dne1* and *dcp2^{its1}*, revealing the redundant
287   function of DCP2 and DNE1 in the establishment of phyllotaxis in the floral meristem. Interestingly, we
288   could identify similar defects in *xrn4,* a mutant affected in the 5'-3' mRNA degradation pathway (P-
289   value 2.2×10^{-16}, Fig. 8), suggesting that the observed phenotype results from an increased defect in
290   mRNA degradation in the *dne1 dcp2^{its1}* double mutant.
291
292   **DISCUSSION**

293   In this study, we identified DNE1, a previously uncharacterized protein harboring an
294   endoribonuclease domain of the NYN family and two OST-HTH domains, as a direct protein partner of
295   DCP1. DNE1 accumulates together with DCP1 in P-bodies and is expressed throughout the plant
296   lifecycle. We found that DNE1 is ubiquitous in streptophytes. This conservation for more than half a
297   billion years suggests an important function. The perfect conservation in plants of aspartates residues
298   known to be crucial for the catalytic activities of NYN-domain enzymes, strongly suggests that the
299   activity of DNE1 is under a significant selection pressure (Matelska et al., 2017). The *in vivo* transient
300   expression of wild-type DNE1 represses the expression of several mRNAs, whereas a catalytic mutant
301   cannot, suggesting that DNE1 catalytic activity targets mRNAs. The constitutive overexpression of
302   DNE1 in stable lines leads to growth defects and a similar gene deregulation signature than
303   plants in which decapping is compromised. Finally, we present genetic evidences of a functional
304   redundancy between DNE1 and DCP2 in controlling the robustness of phyllotactic pattern
305   formation.
306   We initially identified DNE1 in UPF1 IPs, raising the possibility that this protein could be the plant
307   equivalent of the PIN domain endoribonuclease SMG6 in animal (Chicois et al., 2018). We found that,
308   UPF1 co-purifies with DNE1 (44 spectra; Supplementary Table S7) and is also detected with DCP2 (8
309   spectra; Supplementary Table S6). This observation indicates first that UPF1 is coupled with the
310   decapping complex in plants, as described in mammals (Lejeune et al., 2003) and that it is in addition
311   coupled to a protein complex containing DCP1 and the endonuclease DNE1. A recent analysis of RNA
312   fragments stabilized in *xrn4* reports the accumulation of NMD targets intermediates produced by
313   endonucleolytic cleavage in plants (Nagarajan et al., 2019). Our results put DNE1 in the position of
314   being the favored candidate to exert such an activity.

8

315   An interesting parallel can be made between our findings and one of the results of the recent
316   systematic analysis by *in vivo* proximity-dependent biotinylation (BioID) of 119 human proteins
317   associated to mRNA biology (Youn et al., 2018). This analysis identified correlated patterns between
318   endogenous preys and enabled the definition of 144 core components of SGs and P-bodies. Among
319   the P-body components, a correlation cluster appeared around decapping factors (cluster2).
320   Interestingly, this cluster contained the closest homolog of DNE1 in human, the endonuclease MARF1.
321   In both cases, MARF1 and DNE1 represent NYN domain proteins very tightly associated with proteins
322   of the decapping complex. An in-depth molecular phylogenic study across phyla is necessary to reveal
323   whether both genes have a common ancestry, originate from an early horizontal gene transfer or are
324   the results of convergent evolution between evolutionary distant phyla.

325   Our study reveals a synergistic phyllotactic phenotype observed in *dne1 dcp2*, which can lead to two
326   alternative models for DNE1 action. Either DNE1 acts together with the decapping complex, in a
327   specific complex containing DNE1-DCP1-DCP2 working in parallel of the canonical DCP1-DCP2
328   decapping complex, or DNE1 exists in an alternative DNE1-DCP1 complex sharing targets with the
329   decapping complex. The first possibility is reminiscent of the mode of action of its human homologue
330   MARF1, proposed to recruit decapping factors to stimulate the degradation of its target (Nishimura et
331   al., 2018). We do not have experimental data supporting the existence of a DCP1-DCP2-DNE1
332   complex. Our study of proteins associated with DCP1, DCP2 and DNE1 is more in favor of the second
333   hypothesis and suggests the existence in plants, of a protein complex based on DCP1-DNE1 in
334   parallel of the canonical decapping complex based on DCP1-DCP2. Comparing DCP1, DCP2 and
335   DNE1 protein copies per cell (pcc) as found in a recent global proteomic analysis (Bassal et al., 2020)
336   reveal that DCP1 is the more abundant protein (234128 pcc) followed by DCP2 (67345 pcc) and finally
337   DNE1 (791 pcc). This data supports the existence of a main complex containing DCP2 and of an
338   accessory complex containing DNE1. The importance of this accessory complex is revealed by its
339   compensatory effect upon the partial loss of DCP2 function in the weak *dcp2^its1^* mutant, demonstrating
340   its importance for phyllotactic pattern formation. A functional link between DNE1 and DCP2 actions is
341   further supported by our observation that the stable overexpression of DNE1 leads to transcriptomic
342   changes related to the one observed in decapping mutants and to an increased accumulation of
343   targets of the decapping complex (Fig. 7). One way among many to construe this observation is that
344   DNE1 overexpression could compromise the formation of the decapping complex by competing for a
345   common partner, like DCP1. However, a detailed study of the interaction domains between DNE1 and
346   DCP1 will be required in order to test this hypothesis experimentally.

347   Interestingly, the phyllotactic defects observed in *dne1 dcp2^its^* are also detected in *xrn4* mutant,
348   impaired in 5'-3' RNA degradation (Fig. 8). This observation supports a possible genetic redundancy
349   between DCP2 and DNE1 in mRNA degradation. This genetic redundancy also provides a plausible
350   explanation to the absence of deregulated genes in *dne1* single mutant, DNE1 as part of an accessory
351   complex, becoming limiting only in case of DCP2 deficiency. Phyllotaxis is controlled by an intricate
352   hormonal balance involving both auxin and cytokinin (Reinhardt et al., 2003; Besnard et al., 2014).
353   Further studies will be required to decipher the RNA substrates targeted by DNE1, DCP2 and XRN4
354   explaining this observation. Identifying DNE1 targets may also benefit from a recent study indicating

9

355 that the OST-HTH domains of both DNE1 and its homologue MARF1 have affinity for RNA G-
356 quadruplex (G4), a very specific RNA tertiary structure (Ding et al., 2020). These data suggest that
357 both DNE1 and MARF1 can target G4 containing RNAs and open very interesting perspectives for the
358 study of the targets and biological functions of these NYN domain endoribonucleases.

359

360 **MATERIAL AND METHODS**

361 **Plant material**

362 Plant lines used: *dne1-1* (Salk_132521); *vcs-6* (SAIL_831_D08); pDCP1::YFP-DCP1 in *dcp1-3*
363 (SAIL_377_B10); p35S::GFP-DCP2 in *tdt-1* (a *dcp2* mutant)*;* pPABP2::tRFP-PABP2 in WT Col*,*
364 p35S::GFP-DNE1 in *dne1-1,* p35S::GFP-DNE1-D153N in *dne1-1;* p35S::RFP-DNE1 in *dne1-1; dne1-*
365 *2* and *dne1-3* were created by the CRISPR*/Cas9* system using the sgRNA target sequence:
366 TCTTCAGGACGTACATCGCT inserted in pKIR1.1 to target DNE1 NYN domain (Tsutsui and
367 Higashiyama, 2017). For IP experiments plants are grown on soil in long-day light conditions (16/8)
368 until flowering and unopened flower buds are collected. For RNAseq experiments surface sterilized
369 seeds (70% ethanol, 0.1% Triton-X 100, washed 5 min with 100% ethanol) are sown on solid MS
370 medium (MS0255 Duchefa®, 1% agar, 1% sucrose, pH 5.7). After 48h of stratification at 4 °C
371 seedlings are grown in long-day light conditions at 21 °C for 14 days.

372

373 **Plasmids**

374 Sequence from genomic DNA has been cloned in pB7WGF2, pH7WGR2 gateway destination vectors
375 harboring GFP, RFP sequences respectively to produce N-ter tagged versions of DNE1 both wild-type
376 and catalytic mutant D153N. DNE1 and DCP1 sequences amplified from cDNA were cloned into
377 pGBT9 and pGADT7 to perform Y2H.

378

379 **Immunopurifications**

380 Details about samples and replicates of co-immunopurification (IP) experiments are provided in
381 Supplementary Table S1. For IPs 0.3 g of flower buds were ground in 1.5 ml of ice-cold lysis buffer (50
382 mM Tris-HCl pH 8, 50 mM NaCl, 1 % Triton X-100, supplemented with Roche cOmplete, EDTA-free
383 Protease Inhibitor Cocktail). After cell debris removal by centrifugation (twice 10 min at 16,000 g, 4°C),
384 supernatants were incubated for 30 min with 50 µl of magnetic microbeads coupled to anti-GFP
385 antibodies (Miltenyi). Beads were loaded on magnetized µMACS separation columns equilibrated with
386 lysis buffer and washed four times with 200 µl of washing buffer (20 mM Tris-HCl pH 7.5, 0.1 % Triton
387 X-100). Samples were eluted in 100 µl of pre-warmed elution buffer (50 mM Tris-HCl pH 6.8, 50 mM
388 DTT, 1 % SDS, 1 mM EDTA, 0.005 % bromophenol blue, 10 % glycerol). Negative control IPs were
389 performed under the exact same conditions with WT plants. For IPs crosslink, 0.3 g of flower buds
390 were ground during 10 min in 2.25 ml of ice-cold lysis buffer supplemented with 0.375 % formaldehyde
391 (Thermo Fisher Scientific). The crosslinking reaction was quenched by adding glycine at a final
392 concentration of 200 mM for 5 min. After cell debris removal by centrifugation (twice 15 min at 10,000

393   g, 4°C), supernatants were incubated for 45 min with 50 µl of magnetic microbeads coupled to anti-
394   GFP antibodies (Miltenyi). Beads magnetic capture and washing steps were done according to the
395   manufacturer's instructions, except that washes were performed with 50 mM Tris-HCl pH 7.5, 50 mM
396   NaCl, 0.1% Triton X-100, supplemented with Roche cOmplete, EDTA-free Protease Inhibitor Cocktail.
397   Samples were eluted as previously described. Negative control IPs were performed with beads
398   coupled to anti-GFP antibodies in WT plants.

399

400   **Mass spectrometry analysis and data processing**

401   Eluted proteins were digested with sequencing-grade trypsin (Promega) and analyzed by nano
402   LCMS/MS on a QExactive + mass spectrometer coupled to an EASY-nanoLC-1000 (Thermo Fisher
403   Scientific). IP data were searched against the TAIR 10 database with a decoy strategy. Peptides were
404   identified with Mascot algorithm (version 2.5, Matrix Science) and data were imported into Proline 1.4
405   software. IP data were searched against the TAIR 10 database with a decoy strategy. Peptides were
406   identified with Mascot algorithm (version 2.5, Matrix Science) and data were imported into Proline 1.4
407   software (Bouyssié et al., 2020). Proteins were validated on Mascot pretty rank equal to 1, Mascot
408   score above 25, and 1% FDR on both peptide spectrum matches (PSM score) and protein sets
409   (Protein Set score). The total number of MS/MS fragmentation spectra was used to quantify each
410   protein from at least three independent IPs. Volcano plots display the adjusted p-values and fold
411   changes in Y and X-axis, respectively, and show the enrichment of proteins co-purified with tagged
412   proteins as compared to control IPs. The statistical analysis based on spectral counts was performed
413   using a homemade R package (https://github.com/hzuber67/IPinquiry4) that calculates fold change and
414   p-values using the quasi-likelihood negative binomial generalized log-linear model implemented in the
415   edgeR package. The size factor used to scale samples were calculated according to the DESeq2
416   normalization method (i.e., median of ratios method). P-value were adjusted using Benjamini
417   Hochberg method from stats R package.

418

419   **Phylogeny and structural modlisation**

420   Phylogenetic trees were done with the http://www.phylogeny.fr web tool. Multiple alignments have
421   been made using MUSCLE (v3.8.31). Positions with gaps have been eliminated. The phylogenetic
422   tree has been built using the maximum likelihood method implemented in PhyML (v3.1/3.0 aLRT,
423   approximate likelihood-ratio test). Bootstrap values were calculated on 100 iterations. Graphic
424   representation of the tree was done with TreeDyn (v198.3). The structures of AtDNE1 NYN and OST-
425   HTH domains were modelized using Phyre2: Protein Homology/analogYRecognition Engine V
426   2.0 (Kelley et al., 2015). The alignment of the structural models produced with NYN HsMARF (PDB ID:
427   6fdl) and OST-HTH MmMARF1 (PDB ID: 5yad) were done using PyMOL software.

428

429   **Agroinfiltration**

430   Competent agrobacteria (GV3101 pMP90) were transformed with vectors containing fluorescent
431   fusion proteins DNE1 WT, mutant D153N, GFP reporter gene or the silencing suppressor P14. *N.*

432   *benthamiana* leaves were co-infiltrated with bacterial suspension containing DNE1 WT, or D153N,

433   reporter GFP and P14 in a 1:1:1 ratio (Garcia et al., 2014). Infiltrated tissues were collected 3 days

434   after infiltration.

435

436   **Subcellular localization analysis**

437   Seven day-old epidermal roots cells of stable *A. thaliana* lines expressing the desired constructs were

438   imaged using a LSM780 confocal microscope (Zeiss) with a 40X objective. Co-localization analysis

439   was performed with ImageJ as follows: foci in images were determined with a user-supervised local

440   maxima detection method (script available on demand). Local intensities in channels visualizing GFP

441   or RFP fusion proteins were measured for every detected focus and the reported values were then

442   charted in a (IGFP versus IRFP) scatter plot for further qualitative assessment of fluorescent spot

443   content correlation.

444

445   **Libraries preparation and RNA seq analysis**

446   Transcriptomic analysis was performed on biological triplicates of 14 day-old seedlings of the *dne1-1*

447   mutant, two independent DNE1 OE lines analyzed together (P35S-GFP::DNE1), an DNE1_D153N OE

448   line (35S:GFP-DNE1_D153N). Purified total RNAs were quantified by Qubit (Invitrogen) fluorimeter,

449   RNA's quality was tested using Bioanalyzer 2100 (Agilent) system. Two micrograms of RNAs were

450   used for libraries preparation with the mRNA-Seq Library Prep Kit V2 for Illumina Platforms (Lexogen)

451   using manufacturer's instructions. Libraries were sequenced by single read (50 cycles) at GenomEast

452   sequencing platform (IGBMC, Strasbourg) with an Illumina HiSeq 4000. Fastq files were generated

453   using RTA (v2.7.3) and bcl2fatq (v2.17.1.14). Sequences were mapped on *A. thaliana* genome

454   (TAIR10) with Hisat2 (v2.1.0) using default parameters except for intron lengths that have been

455   reduced at 2000 bp. After alignment, the number of reads mapped to each gene were counted with

456   HTseqcount   (v0.10.0)   using   the   annotation   document

457   Araport11_GFF3_genes_transposons.201606.gff. Statistical analysis was performed on R (v3.6) with

458   DEseq2 package (v1.24.0) and its implemented negative binomial distribution. Adjusted p-values were

459   calculated using the Benjamini and Hochberg method.

460

461   **Statistical analysis**

462   Statistical analyses were performed using R 3.6.1, Rstudio 1.2 and the following R packages: DEseq2

463   1.24.0, stats 3.6.1, multcompView 0.1-8, Limma 3.40.6. For all analyses, a p-value of 0.05 was

464   defined as the threshold of significance. For each figure, the exact value of n and the test used for the

465   statistical analysis are indicated in the figure or in the corresponding legend. Fold change and p-

466   values in Fig. 1b, 1c, 2b and 3 were computed using the quasi-likelihood negative binomial

467   generalized log-linear model implemented in the edgeR package. Correlation coefficients and their

468   associated p-value shown in Fig. 4 were calculated using Pearson correlation method. Statistical

469   significance shown in Fig. 7E and 7G were obtained using Pairwise Wilcoxon Rank Sum Tests with

470   data considered as paired and unpaired, respectively. In Fig. 7G, the proportion of uncapped RNA

12

471 was retrieved from Anderson et al. 2018 (GSE108852) for all transcripts detected in both this dataset
472 and our RNA experiment. The proportion of uncapped RNA were measured in Col0 and corresponds
473 to the ratio of the RPM from GMUCT for a given transcript (2 biological replicates) normalized by the
474 RPM for that same transcript (4 biological replicates). Boxplot analysis were then performed to
475 compare the proportion of uncapped RNA in all transcripts, non-regulated transcripts, and in transcript
476 either up or down-regulated in D153N transgenic lines and *vcs* mutant. The identification of statistically
477 significant overlap between gene-expression signatures in Venn diagrams shown in Fig. 7 are
478 provided in TableS9 and were computed using the hypergeometric distribution implemented in the
479 stats R package (v3.6.1). Statistical significance shown in Supplementary Fig S5 were obtained using
480 the Limma moderated F-test. All p-value were adjusted using the Benjamini Hochberg method.

481

482 **Quantitative real-time reverse transcriptase PCR (qRT-PCR)**

483 Three to six independent biological replicates of 14 days old seedlings were analyzed (see
484 Supplementary Fig S5). RNA was extracted using TRI Reagent® (Sigma), genomic DNA was
485 removed using the DNase RQ1 (PROMEGA), cDNA was synthesized using a mix of random
486 hexamers and oligo d(T) by Superscript IV (Invitrogen). Technical triplicates qRT-PCR were performed
487 with SYBR-green I Master Mix (Roche) using Light Cycler 480 (Roche), following the manufacturer's
488 instructions. mRNA abundance was compared to two reference genes *ACT2* and *TIP41* (primer used
489 in Table S12). The ΔΔCt method was used to calculate relative RNA abundance.

490

491 **Phyllotactic pattern measurements**

492 Phyllotactic pattern was assessed on 35 successive siliques per plant on the main stem, starting from
493 the first silique, on fully grown stems. Divergence angles were measured using a dedicated device as
494 previously described (Peaucelle et al 2007). Angles were measured between the insertion points of
495 two successive floral pedicels, independently of the outgrowth direction of the pedicel. Phyllotaxy
496 orientation for each individual, was set to the direction giving the smallest average divergence angle.
497 Measurements were performed on between three and four biological replicates, analysis of individual
498 replicates are shown in Supplementary Fig S6.

499

500 **Accession numbers**

501 Sequence data from this article can be found in the GenBank data libraries under accession numbers
502 At1g15560 (DNE1); At1g08370 (DCP1); At5g13570 (DCP2); At3g13300 (VCS); AT3G13290 (VCR);
503 At2g45810 (RH6); At4g00660 (RH8); At3g61240 (RH12); AT5G47010 (UPF1) At3g58570 (RH52);
504 At4g34110 (PABP2); Niben101Scf05368g03015 (NbRBC); Niben101Scf00508g00007 (NbPLAST);
505 Niben101Scf11490g00008 (NbTHIAM).

506

507 **Large datasets**

13

508 RNAseq datasets generated during this study have been deposited in NCBI's Gene Expression

509 Omnibus and are accessible through GEO Series accession number GSE155806.

510 Mass spectrometry proteomics raw data have been deposited to the ProteomeXchange Consortium

511 via the PRIDE partner repository with the dataset identifier n° PXD020780, reviewer access:

512 reviewer17858@ebi.ac.uk /Za2LUVLe.

513 Data shown in Supplementary Figure S1 were extracted from the pastDB project at

514 http://pastdb.crg.eu/; (Martín et al., 2021).

515

516 **SUPPLEMENTAL DATA**

517 The following supplemental materials are available.

518 **Supplementary Figure S1.** Graphical representation showing normalized RNA-seq data for the

519 expression of *DNE1*, *DCP1* and *DCP2* in *Arabidopsis* at 90 different developmental stages.

520 **Supplementary Figure S2.** Accumulation levels of RFP-DNE1 and RFP-D153N in the transient

521 expression assay.

522 **Supplementary Figure S3.** Characterization of GFP-DNE1 transgenic lines.

523 **Supplementary Figure S4.** Characterization of GFP-D153N transgenic lines.

524 **Supplementary Figure S5.** Q-PCR validations of transcriptomic data on selected deregulated genes.

525 **Supplementary Figure S6.** Density plots showing the quantification of divergent angles for each

526 biological replicate separately.

527 **Supplementary Table S1.** Details of biological material used for IPs.

528 **Supplementary Table S2.** List of proteins significantly enriched in YFP-DCP1 IPs.

529 **Supplementary Table S3.** List of proteins significantly enriched in GFP-DCP2 IPs.

530 **Supplementary Table S4.** List of proteins significantly enriched in GFP-DNE1 IPs.

531 **Supplementary Table S5.** List of proteins significantly enriched in crosslinked YFP-DCP1 IPs.

532 **Supplementary Table S6.** List of proteins significantly enriched in crosslinked GFP-DCP2 IPs.

533 **Supplementary Table S7.** List of proteins significantly enriched in crosslinked GFP-DNE1 IPs.

534 **Supplementary Table S8.** Amino acid identity and similarity of DNE1 protein domains (NYN, OST1,

535 OST2) from representative streptophytes species.

536 **Supplementary Table S9.** Comparison between lists of differentially expressed genes using

537 hypergeometric test.

538 **Supplementary Table S10.** Statistical analysis of the Q-PCR validations by moderated t-test.

539 **Supplementary Table S11.** Aligned sequences from *dne1-2* and *dne1-3* CRISPR-Cas9 mutants.

540 **Supplementary Table S12.** Analysis of the distribution of divergent angles in different biological

541 replicates using the Kolmogorov-Smirnov test.

542 **Supplementary Table S13.** DNA oligonucleotides used in this study.

598   DNE1 crosslinked IPs (n=4), results provided in Supplementary Table S7. Control IPs (n=4) for results

599   presented in A, B and C**.** Colored points (yellow and magenta) indicate proteins significantly enriched

600   with Log FoldChange (Log2FC) > 1 and adjusted p-value (adjp) < 0.05. Yellow points highlight

601   expected partners of the decapping complex and DNE1, cytosolic exoribonucleases XRN4 and SOV

602   and the NMD protein UPF1.

603

604   **Figure 4. DNE1 co-localizes with DCP1 and UPF1 in p-bodies.**

605   **(A)** Confocal microscopy co-localization study of DNE1 with the stress granule marker PAB2-RFP, the

606   P-body markers YFP-DCP1and UPF1-RFP in stable *Arabidopsis* transformants. A 30 min heat stress

607   at 37°C was applied to GFP-DNE1 PAB2-RFP to induce stress granule formation. Scale bar: 10µm. **(B)**

608   Dot plot showing the quantification of foci co-localization in the green (ch1, y-axis) and red (ch2, x-axis)

609   channels; The number of foci analyzed (n) is indicated on the plot. The calculated Pearson's

610   correlation coefficient (r) and p-values are indicated.

611

612   **Figure 5. DNE1 is an evolutionary conserved NYN domain protein harboring two OST-HTH**

613   **modules.**

614   **(A)** DNE1 phylogenetic tree obtained with the maximum likelihood method. Bootstrap values are

615   indicated for each node. **(B)** Schematic domain structure of DNE1. In purple the catalytic NYN domain,

616   in orange the OST-HTH predicted RNA binding domains. **(C)** Multiple alignment of amino-acid

617   sequences of NYN domains from DNE1 plant orthologs as in (A). In purple the conserved aspartic

618   acid residues important for catalysis. **(D)** Multiple alignments of amino-acid sequences of OST-HTH 1

619   domains from DNE1 plant orthologs as in (A). **(E)** Structural alignment of the predicted tridimensional

620   structure of AtDNE1 NYN domain sequence (in purple) with the tridimensional crystal structure of

621   *Hs*MARF1 NYN domain [6fdl, (Nishimura et al. 2018), in blue]. Conserved D residues are shown in

622   orange. **(F)** Structural alignment of the predicted tridimensional structure of AtDNE1 OST-HTH1

623   domain sequence (in yellow) with the tridimensional crystal structure of *Mm*MARF1 OST-HTH1

624   domain [5yad, (Yao et al., 2018), in orange].

625

626   **Figure 6. Transient expression of DNE1 impairs the expression of a co-expressed and**

627   **endogenous mRNAs.**

628 Northern blot analysis showing the impact of the co-expression of DNE1 WT (WT) or DNE1 D153N

629 (D153N) on mRNA accumulation in *N. benthamiana*, empty plasmid (-) is used as a control. Methylene

630 blue staining showing ribosomal RNAs (rRNA) and a U6 probe are used as loading controls.

631

632 **Figure 7. Altering DNE1 expression impairs plant growth and leads to the same gene**

633 **deregulation signature than mutations in VCS and DCP2.**

634 **(A)** Pictures of WT, *dne1-1*, GFP-DNE1 and GFP-D153N overexpressors (OE) 14 days after planting.

635 Scale bar: 1cm. **(B)** Analysis of GFP-DNE1 and GFP-D153N transgenic lines by Western blot using

636 anti GFP antibody. Two independent plant lines 1 and 2 are analyzed for GFP-DNE1 and one for the

637 GFP-D153N. Coomassie staining used as a loading control (Coom). **(C)** Histogram showing the global

638 changes in gene expression based on RNAseq analyses in *dne1-1*, GFP-DNE1 OE, GFP-D153N OE

639 and *vcs-6* compared to WT. Genes were considered as upregulated and downregulated when

640 adjusted p-value<0.05 and Log2FC>0.75 or Log2FC<-0.75, respectively (n≥3). Y-axis represent the

641 number of deregulated genes **(D)** Venn diagrams showing comparisons between significantly

642 upregulated or downregulated genes in DNE1 OE or D153N OE lines and *vcs-6*. **(E)** Boxplot

643 comparing the change levels (Log2FC) between the different genotypes of the 64 genes that are

644 commonly upregulated in both DNE1 and D153N lines. **(F)** Venn diagrams showing comparisons

645 between significantly upregulated or downregulated genes in D153N OE, *vcs-6* and the weak *dcp2*

646 mutant *tdt-1.* **(G)** Box plot showing the proportion of uncapped transcripts as found by GMUCT in

647 (Anderson et al., 2018) for all genes detected in RNAseq (all), genes not deregulated in any

648 genotypes (other) and genes deregulated in *vcs-6* or D153N OE lines. Letters in (E) and (G) show

649 statistically different groups based on a Wilcoxon rank-sum test.

650

651 **Figure 8. Synergistic effect of mutations in *dne1* and *dcp2* on phyllotactic pattern.**

652 **(A)** Pictures showing representative stems from the WT, *dcp2^{its1}*, *dne1-2*, *dne1-2 dcp2^{its1}*, *dne1-3*,

653 *dne1-3 dcp2^{its1}* and *xrn4-3* plants. **(B)** Density plots showing the quantification of divergent angles from

654 the genotypes shown in A. The analysis was performed on 3 to 4 biological replicates. Differences

655 between divergent angles distribution was assessed using the Kolmogorov-Smirnov test, complete

656 results are shown in Supplementary Table S12. The analysis is shown for each biological replicates

657 separately in Supplementary Fig S6.

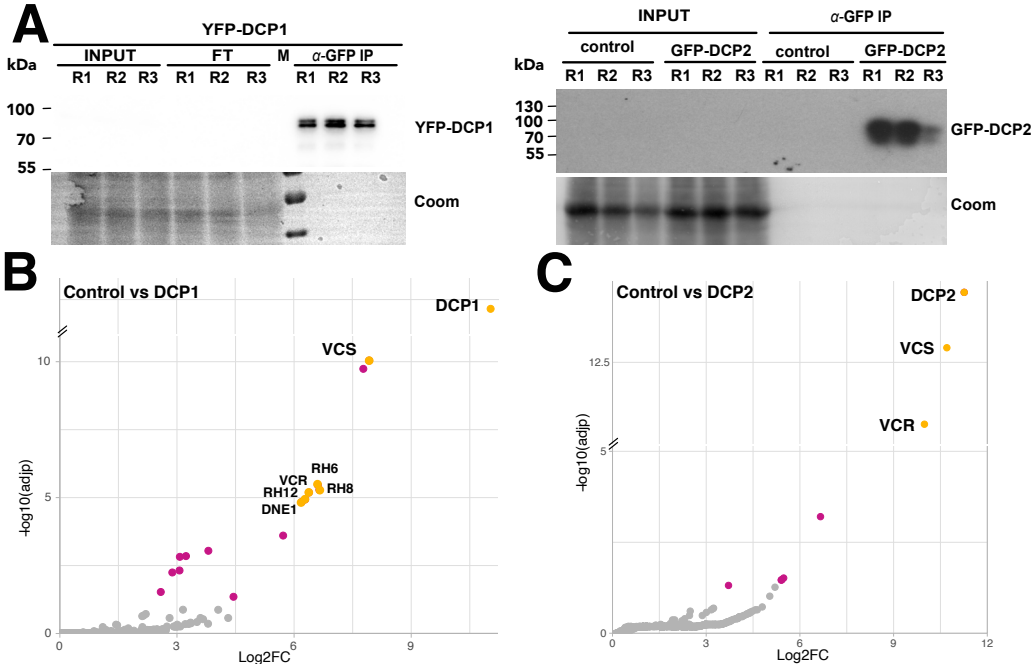

Figure 1. Identification of proteins associated with the decapping complex components DCP1 and DCP2. (A) Western blot analysis of GFP immunoprecipitates (IPs) performed in triplicate on extracts from YFP-DCP1 *dcp1-3* and from GFP-DCP2 *tdt-1* complemented lines. Wild-type plants used as negative controls are shown in the right panel (control). **(B)** Semi-volcano plot of proteins enriched in YFP-DCP1 IPs (n=6), results provided in Supplementary Table S2. **(C)** Semi-volcano plot of proteins enriched in GFP-DCP2 IPs (n=3), results provided in Supplementary Table S3. Control IPs (n=6) for results presented in B and C. Colored points (yellow and magenta) indicate proteins significantly enriched with Log FoldChange (Log2FC) > 1 and adjusted p-value (adjp) < 0.05. Yellow points highlight expected partners of the decapping complex and DNE1. Coomassie staining (Coom), protein ladder (M), flow-through (FT) and immunoprecipitated fractions (α-GFP IP).
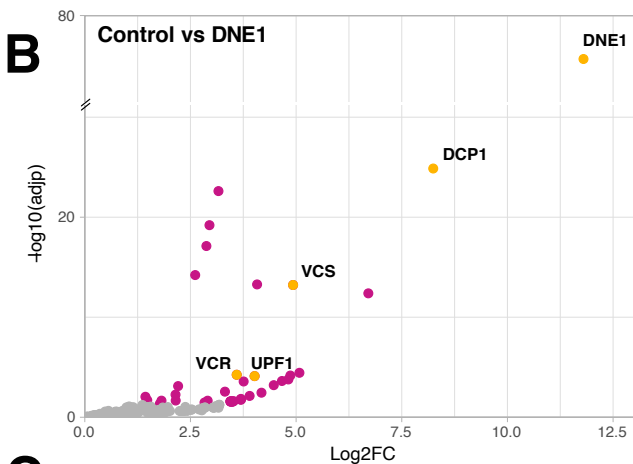

Figure 2. Identification of proteins associated with the DCP1-associated endonuclease DNE1

(A) Western blot analysis of GFP IPs performed in triplicate, on extracts from GFP-DNE1 *dne1-1* lines. (B) Semi-volcano plot of proteins enriched in GFP-DNE1 IPs (n=8), control IPs (n=9), results provided in Supplementary Table S4. The volcano plot is represented as in Fig. 1. (C) Specific growth on selective media for the DCP1-DNE1 and DCP1-D153N combinations highlights the direct interaction between DCP1 and DNE1. Minimal SD medium –LT, -LTH and –LTAH were used, in which Adenine (A); Histidine (H); Leucin (L); Tryptophan (T). 5mM 3-AT was used to avoid autoactivation. T7: pGADT7 AD (LEU2); T9: pGBT9 BD (TRP1).
Figure 3. Crosslinked immuno-precipitations improve the sensitivity for the identification of proteins associated with DCP1, DCP2 and DNE1. (A) Semi-volcano plot of proteins enriched in YFP-DCP1 crosslinked IPs (n=4), results provided in Supplementary Table S5. **(B)** Semi-volcano plot of proteins enriched in GFP-DCP2 crosslinked IPs (n=4), results provided in Supplementary Table S6. **(C)** Semi-volcano plot of proteins enriched in GFP-DNE1 crosslinked IPs (n=4), results provided in Supplementary Table S7. Control IPs (n=4) for results presented in A, B and C**.** Colored points (yellow and magenta) indicate proteins significantly enriched with Log FoldChange (Log2FC) > 1 and adjusted p-value (adjp) < 0.05. Yellow points highlight expected partners of the decapping complex and DNE1, cytosolic exoribonucleases XRN4 and SOV and the NMD protein UPF1.
Figure 4. DNE1 co-localizes with DCP1 and UPF1 in p-bodies. (A) Confocal microscopy co-localization study of DNE1 with the stress granule marker PAB2-RFP, the P-body markers YFP-DCP1and UPF1-RFP in stable *Arabidopsis* transformants. A 30 min heat stress at 37°C was applied to GFP-DNE1 PAB2-RFP to induce stress granule formation. Scale bar: 10μm. **(B)** Dot plot showing the quantification of foci co-localization in the green (ch1, y-axis) and red (ch2, x-axis) channels; The number of foci analyzed (n) is indicated on the plot. The calculated Pearson's correlation coefficient (r) and p-values are indicated.
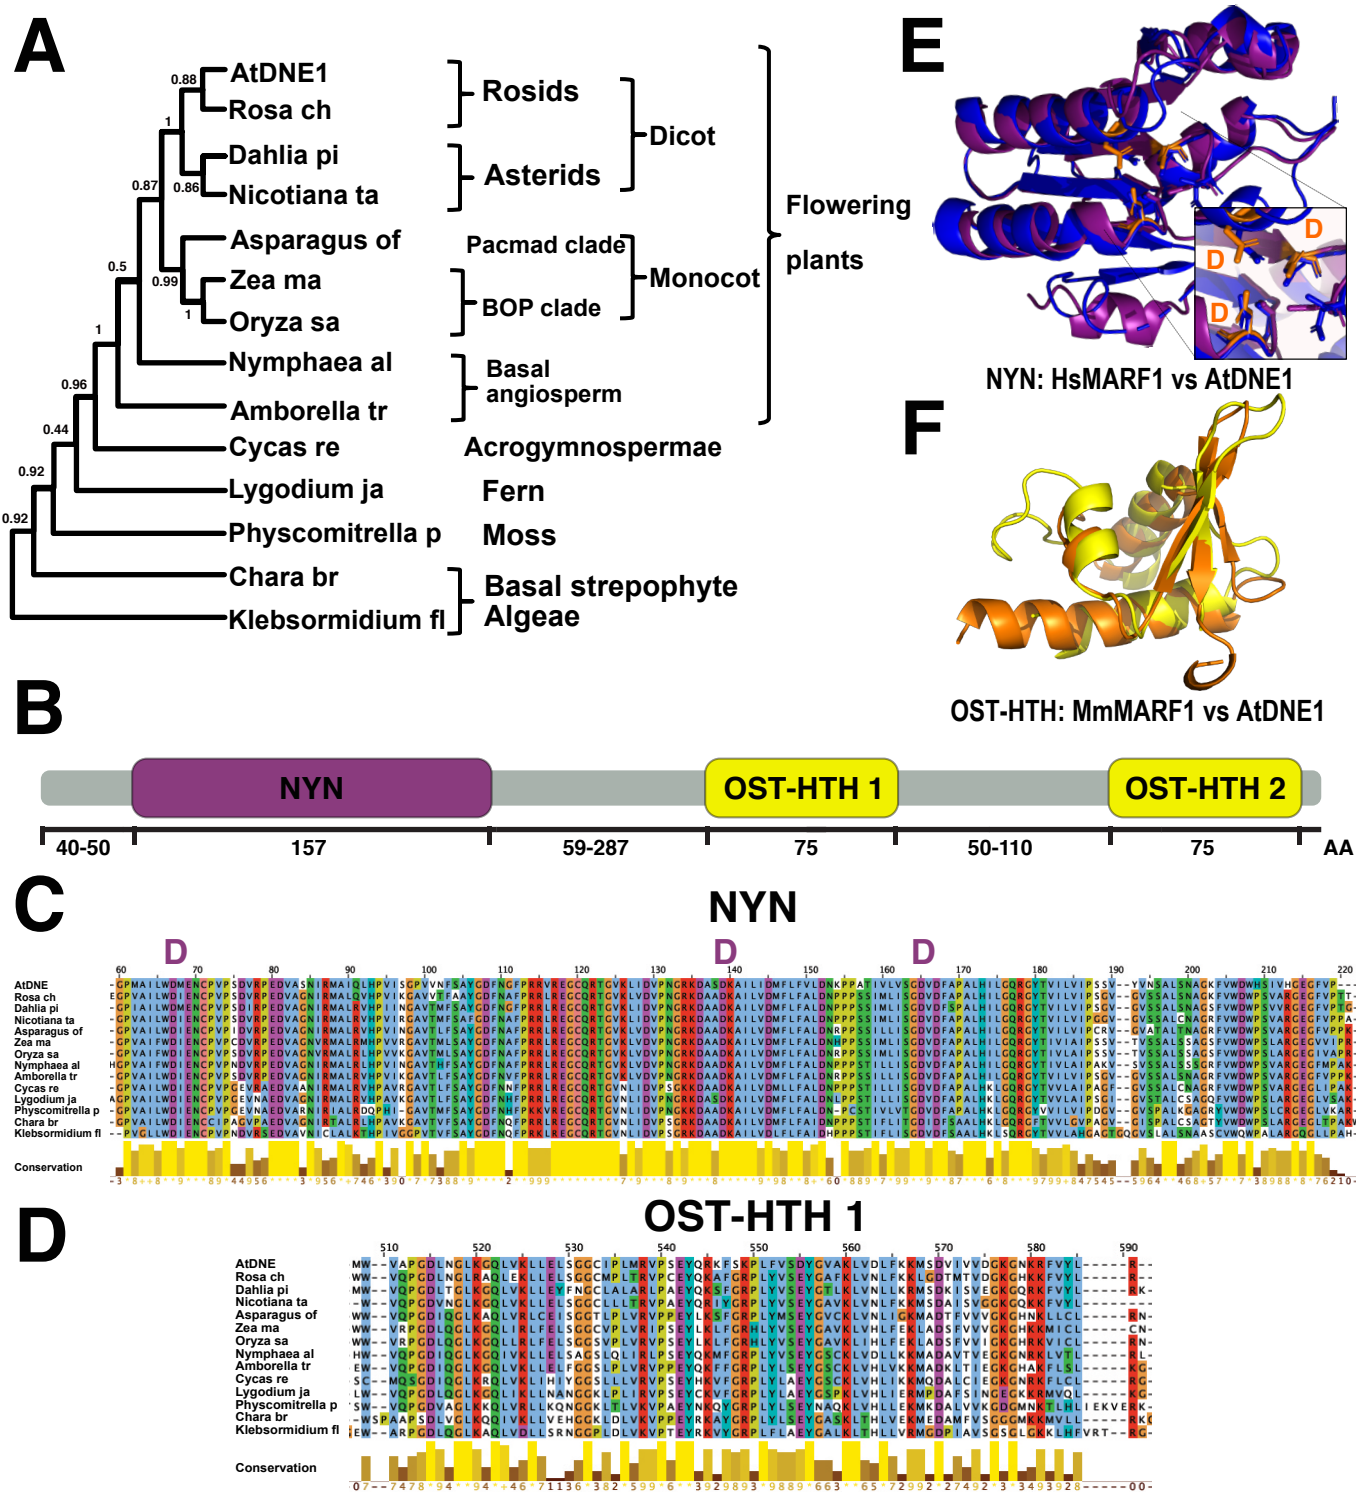

Figure 5. DNE1 is an evolutionary conserved NYN domain protein harboring two OST-HTH modules. (A) DNE1 phylogenetic tree obtained with the maximum likelihood method. Bootstrap values are indicated for each node. **(B)** Schematic domain structure of DNE1. In purple the catalytic NYN domain, in orange the OST-HTH predicted RNA binding domains. **(C)** Multiple alignment of amino-acid sequences of NYN domains from DNE1 plant orthologs as in (A). In purple the conserved aspartic acid residues important for catalysis. **(D)** Multiple alignments of amino-acid sequences of OST-HTH 1 domains from DNE1 plant orthologs as in (A). **(E)** Structural alignment of the predicted tridimensional structure of AtDNE1 NYN domain sequence (in purple) with the tridimensional crystal structure of *Hs*MARF1 NYN domain [6fdl, (Nishimura et al. 2018), in blue]. Conserved D residues are shown in orange. **(F)** Structural alignment of the predicted tridimensional structure of AtDNE1 OST-HTH1 domain sequence (in yellow) with the tridimensional crystal structure of *Mm*MARF1 OST-HTH1 domain [5yad, (Yao et al., 2018), in orange].
Figure 6. Transient expression of DNE1 impairs the expression of a co-expressed and endogenous mRNAs. Northern blot analysis showing the impact of the co-expression of DNE1 WT (WT) or DNE1 D153N (D153N) on mRNA accumulation in *N. benthamiana*, empty plasmid (-) is used as a control. Methylene blue staining showing ribosomal RNAs (rRNA) and a U6 probe are used as loading controls.
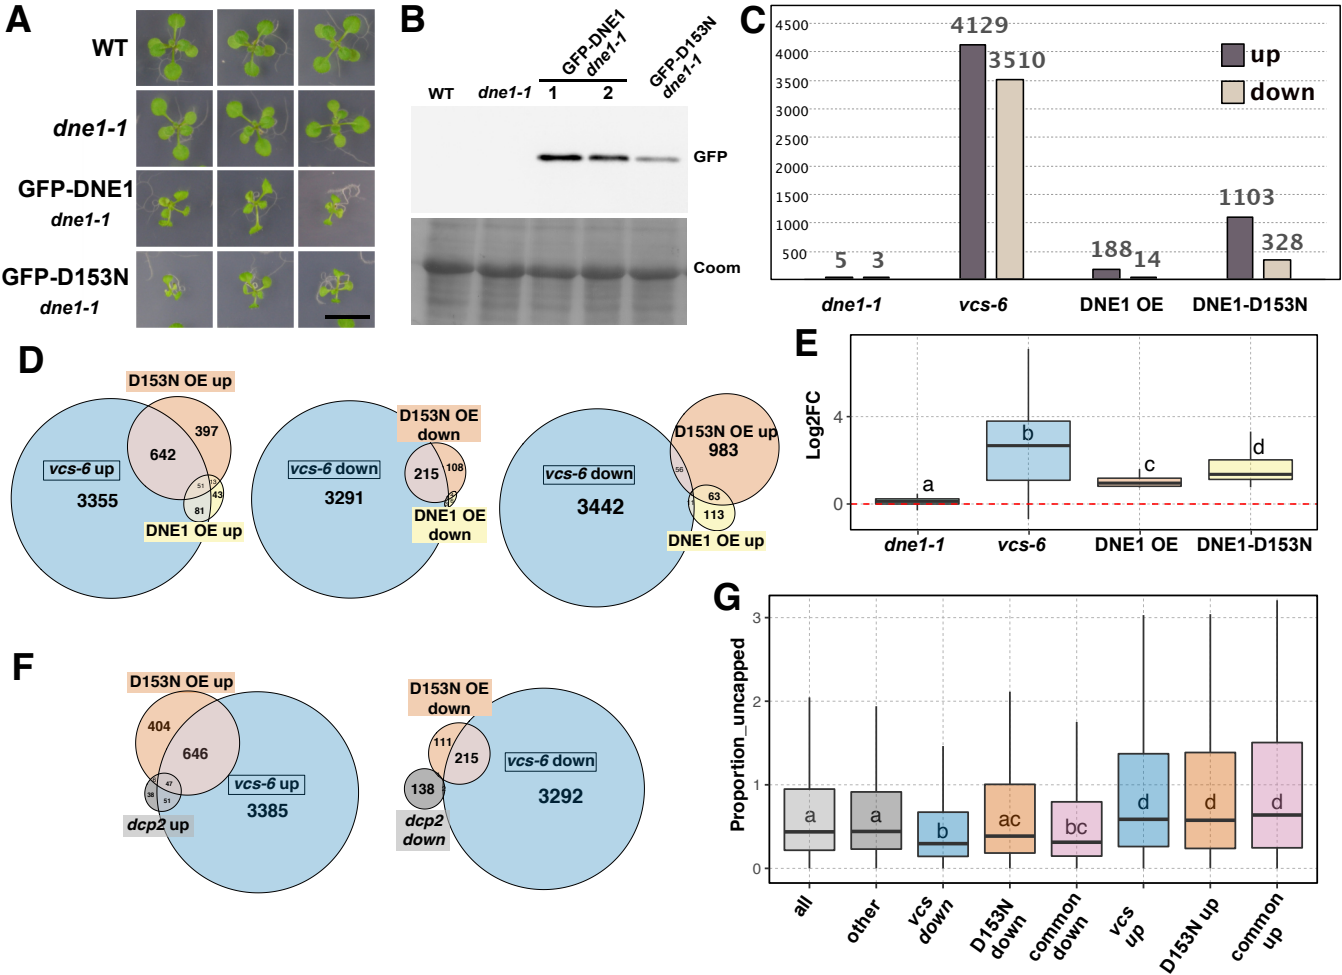

Figure 7. Altering DNE1 expression impairs plant growth and leads to the same gene deregulation signature than mutations in VCS and DCP2. (A) Pictures of WT, *dne1-1*, GFP-DNE1 and GFP-D153N overexpressors (OE) 14 days after planting. Scale bar: 1cm. **(B)** Analysis of GFP-DNE1 and GFP-D153N transgenic lines by Western blot using anti GFP antibody.
