

## Supplementary Material

**Table S1. Branch length transformations used for phylogenetically independent contrasts.** Variable names are listed in Table 3. Abbreviations: exp., exponential transformation; Gra., Grafen's transformation; ln, natural logarithm transformation; Nee, Nee's transformation;  $\rho_x$ , Grafen's rho transform, where x indicates the value of rho; untr., untransformed branch lengths.

## Tables SR1 to SR30 – Results of traditional and PIC regressions

As indicated in [Table 3](#), the following tables present the regression results for each variable. Both the results using traditional regression methods and phylogenetically independent contrasts (PIC) are shown for the whole sample and each of the subsamples (fissipeds, by Family, and by locomotor type). In each case, it is indicated (in the “sim.” columns) whether the theoretical values proposed by the geometric similarity hypothesis (G), the elastic similarity hypothesis (E), or both (B), are included in the 95% confidence interval for the slope  $b$  (95% CI $_b$ ). Furthermore, when neither theoretical value is included in the 95% CI $_b$ , it is indicated whether there is positive allometry (+;  $b$  is higher than both theoretical values), negative allometry (−;  $b$  is lower than both theoretical values), or both (nei.;  $b$  is higher than one theoretical values and lower than the other). Finally, the results of the comparison between the allometric coefficients obtained with each methodology are presented in the last column ( $b_{\text{trad}} \neq b_{\text{PIC}}$ ): a cross (×) indicates no significant differences, while a tick (✓) denotes that the slopes are significantly different from each other ( $p < 0.05$ ).

Variable names and abbreviations are given in [Table 3](#), while the following abbreviations are common to all following tables: 95% CI $_a$ , 95% confidence interval for the coefficient  $a$ ; 95% CI $_b$ , 95% confidence interval for the allometric coefficient  $b$ ; n, sample size; n.s., unable to test differences due to non-significant regression; R, correlation coefficient; sim., similarity. Results in *grey italics* denote non-significant regressions.

## Tables SR31 to SR59 – Results of the complex allometry tests

In each case, it is indicated (in the “ $D \neq I$ ” column) whether the exponent of complex allometry ( $D$ ) is significantly different from 1. Results in *grey italics* denote non-significant regressions. Variable names are listed in Table II.3. Abbreviations: 95% CI<sub>C</sub>, 95% confidence interval for the coefficient ( $C$ ); 95% CI<sub>D</sub>, 95% confidence interval for the exponent of complex allometry ( $D$ ); 95% CI<sub>ln A</sub>, 95% confidence interval for  $\ln A$ ; n, sample size; n.c., the model did not converge in a realistic solution; n.s., although the model did converge in a realistic solution, it was not significant according to the associated correlation coefficient (R).
