ABSTRACT

The translational isoform of full-length p53, Δ40p53, modulates the p53 pathway. We previously showed that Δ40p53 regulates miR-186-5p–YY1 axis, independent of p53, to decrease cell proliferation. In this study, we screened small RNA sequences globally to identify miRNAs differentially regulated by Δ40p53 and p53. We report that the expression of certain miRNAs is exclusively regulated by Δ40p53. Overexpression of Δ40p53, but not full-length p53, substantially downregulated expression of the novel miR-4671-5p. However, upon overexpression of different ratios of Δ40p53 and FLp53, miR-4671-5p levels changed which implies that this novel miRNA is not a direct but a p53 modifiable target. Predicted miR-4671-5p targets included N-sulfoglucoasamine sulfohydrolase (SGSH), cyclin-dependent kinases (CDK) 11B and CDK5 regulatory subunit 1 (CDK5R1). Overexpression of miR-4671-5p directly inhibited SGSH and consequently triggered intra-S-phase cell cycle arrest. Δ40p53-miR-4671-5p-SGSH axis emerges as a novel axis capable of regulating cell cycle progression. SGSH gene expression levels have potential prognostic relevance on survival that trends in the opposite direction of miR-4671-5p levels associated with the same cancer types, supporting a possible physiological relevance of the interaction. These results enhance understanding of Δ40p53 functions mediated by miRNAs that help to maintain metabolic and cellular homeostasis independently of FLp53.

Keywords: p53 isoform, Δ40p53, miR-4671-5p, SGSH, Cell cycle regulation

INTRODUCTION

Cellular stress responses are multifaceted and involve damage recognition and repair, including that of DNA, to minimize the risk of genetic instability (1). p53 binds DNA and plays a central role in protecting genomic integrity. Under genomic stress, p53 causes cell cycle arrest and hinders the proliferation of cells with damaged DNA (2). The functional activities of p53 are lost in multiple human cancers due to protein inactivation or gene mutations (3). The p53 pathway is regulated by several factors, among which the role of p53 isoforms is crucial because these can alter transcriptional activation of p53 targets and thus affect its functions (4). Twelve p53 isoforms are produced via various mechanisms to bear N-terminal (FL/Δ40/Δ133/Δ160) and C-terminal (α/β/γ) diversity (5), and each is differentially expressed in normal and tumor tissues in various types of cancer (6,7). Among these, the only translational isoform of p53 is Δ40p53, and it critically sculpts p53 functions (8).
previously identified two internal ribosome entry sites (IRESs) within p53 mRNA, where one
IRES generates the full-length p53 (FLp53) protein, whereas initiation at the other generates
Δ40p53 (9). We have also shown that several translation initiation factors are critical for the
differential regulation of IRES activity under various types of stress (10,11).

FLp53 has a strong affinity for, and can form homo-tetramers and hetero-tetramers with
Δ40p53, because they share oligomerization domains (12). Furthermore, Δ40p53 can regulate
the functional activity of p53, which directly affects cellular processes (13), as well as critical
cellular processes, such as the cell cycle, proliferation, and senescence. The IRESs driving
p53 isoforms have different cell cycle phase-dependent activities, with IRES for FLp53 being
active at the G2–M transition and IRES for Δ40p53 being the most active at the G1–S
transition (9). In addition to regulating p53 activity, Δ40p53 retains the second transcriptional
activation domain in FLp53 and induces the expression of various genes independently of
FLp53,—(14-16). Δ40p53 also induces 14-3-3σ and G2 arrest but does not affect G1
progression (17,18). It transactivates Bcl-2 Associated X-protein and Growth Arrest and
DNA Damage-inducible 45 in p53-null cells (8). The Nanog-IGF1 axis is also modulated by
Δ40p53/FLp53 hetero-oligomers, thus controlling the switch from pluripotency to
differentiation (19). The proliferation of pancreatic β cells and glucose homeostasis is
controlled by Δ40p53 in mice (20). At basal levels, Δ40p53 and p53 similarly suppress
cellular mobility and proliferation in breast cancer (21). Contrary to its tumor suppressive
role Δ40p53 independently activates the netrin-1 promoter and promotes cell survival (22).
We found that Δ40p53 (and not FLp53) uniquely regulates miR-186-5p, which can
downregulate expression of the known oncogene Ying Yang 1 (YY1) protein, thereby
decreasing cell proliferation (23).

This study aimed to globally identify those miRNAs that are differentially regulated by
Δ40p53(α) and p53(α). We assessed changes in miRNA expression in lung and colon cancer
cell lines cells expressing either or both FLp53(α) and Δ40p53(α) to identify such differential
miRNA regulation.
MATERIALS AND METHODS

Cell lines and transfections

We have used three cell lines in the current study: H1299 (lung adenocarcinoma cell line lacking p53 or Δ40p53), HCT116 p53+/+ cells (colon carcinoma cell line harboring wild-type p53; hereafter called HCT116+/+); and HCT116 p53-/- cells (colon carcinoma cell line harboring only Δ40p53; hereafter called HCT116-/-). These cells were maintained in DMEM (Sigma) with 10% Foetal Bovine Serum (GIBCO, Invitrogen). 70%-80% confluent monolayer of cells was transfected with various plasmid constructs using Lipofectamine 2000 (Invitrogen) and Turbofectamine in Opti-MEM (Invitrogen). The medium was replaced with DMEM (with antibiotic) and 10% FBS four hours later. The cells were harvested and processed as required at the desired time point.

Small RNA Sequencing

RNA Extraction

Total RNA was isolated from control (only vector), p53, Δ40p53, 14A (p53 and Δ40p53) transfected H1299 cells using TRIzol and PureLink RNA mini kit (Ambion) according to the manufacturer’s instructions. Quality of isolated total RNA was checked using Agilent RNA 6000 Nano chips in 2100 Bioanalyzer (Agilent) and NanoDrop spectrophotometer (Thermo Scientific) and quantitation was performed in Qubit using Quant-iT RNA assay kit broad range (Thermo Scientific). Total RNA samples with RNA integrity number (RIN) >7 was selected for Illumina small RNA sequencing library preparation.

Library Preparation

Small RNA sequencing library preparation was performed using Illumina® TruSeq® Small RNA Library Prep Kit according to the manufacturer's protocol. One microgram of the total RNA sample was used for library preparation, and adapters were ligated to 3' and 5'ends of each RNA molecule. Subsequent reverse transcription and amplification were performed to generate a cDNA library, which was further gel purified to select bands between 145-160 bp to prepare a final small RNA sequencing library for clustering and sequencing. Single read 1 x 50 bp sequencing of these libraries was performed in HiSeq-2500 (Illumina).

RNA-seq data analysis
FASTQ files generated for each sample were checked for quality, and then adapter trimming was performed using the cutadapt2 tool (v1.8.1). Adapter trimmed FASTQ files were aligned to the hg19 reference sequence using the mapper module of the miRDeep2 software package. The accepted aligned FASTA files were processed using miRDeep2 module where known mature, precursor miRNAs from humans and mature miRNAs from other species were provided (downloaded from miRBase database) as input. It identified known and novel miRNAs expressed. miRDeep2 module quantifies the expression of the known miRNAs and gives normalized read counts (reads per million: RPM) for each known precursor miRNA. Average RPM values were calculated where a single mature miRNA had multiple precursor miRNAs. DESeq2 was used to identify differentially expressed miRNAs.

**Plasmids and constructs**

pGFP-hp-p53- 5’UTR-cDNA (14A): It expresses both FLp53 and ∆40p53 (a generous gift from Dr. Robin Fahraeus, INSERM, France). pGFP-hp-p53-5’UTR (A135T)-cDNA which expresses only ∆40p53 and pGFP-hp-p53- 5’UTR (A251G/T252 C/G253T)-cDNA which expresses only full-length p53 (p53FL) (23). miR 4671-5p and miR-34a-5p overexpression construct cloning were done by annealing double-stranded oligos of a mature miR-4671-5p and miR-34a-5p respectively, along with the hairpin sequence in the middle between BglII and XhoI in pSuper vector. pCD-Luc-SGSH-3’UTR and pCD-Luc-CDK5R1-3’UTR containing SGSH and CDK5R1 3’UTRs (respectively) were used in the study. They were cloned between XhoI and XbaI downstream of the luciferase gene in the pCD-Luc vector. pCD-Luc-SGSH-3’UTR mutant and pCD-Luc-CDK5R1 mutant have been used. Both the mutants containing 3’UTRs with a mutation in the miR-4671-5p binding site were used in the luciferase experiments.

**siRNA transfections**

HCT116+/+ and HCT116-/- cells were transfected with 30 nM si p53 RNA (IDT). 5’-AACCUCUUGGUGAACCUUAGUACCU-3’ is the sequence for p53 siRNA, directed against the 3’UTR of p53; therefore, it targets both p53 as well as ∆40p53. In the experiments, a non-specific siRNA (Dharmacon) was used as a control.

**Western Blot analysis**

Protein concentrations of the extracts were assayed by Bradford (Bio-Rad), and equal amounts of cell extracts were separated by SDS 12% PAGE and transferred to nitrocellulose.
membrane (Bio-Rad). Samples were then analyzed by Western blotting using a rabbit-raised anti-p53 polyclonal antibody (CM1, a kind gift from Dr. Robin Fahraeus, INSERM, France and Prof. J.C. Bourdon, of University of Dundee, UK), followed by secondary antibody (horseradish peroxidase-conjugated anti-mouse or anti-rabbit IgG; Sigma). SGSH protein has been detected using anti-SGSH Antibody (Abclonal, Cat. No. A8148). CDK11B protein has been detected using anti-CDK11B Antibody (Abclonal Cat. No. A12830). CDK5R1 protein has been detected using anti-CDK5R1 Antibody (Abclonal Cat. No. A14497)

**RNA isolation and Real-time PCR**

According to the manufacturer's protocol, total RNA was isolated from cells with TRI Reagent TM (Sigma). The isolated RNA was treated with 10 units of DNase I (Promega), extracted with acidic phenol-chloroform, and precipitated with 3 M sodium acetate (pH 5.2) and 2.5 volumes of absolute alcohol. RNA amount was quantified with Nano-spectrophotometer, and cDNAs were synthesized using specific reverse primers and MMLV RT (Revertaid™ Thermo Scientific) at 42°C for 1 h, according to standard protocol. At the same time, 2-5µg of total RNA has been used to check mRNAs' expression. 50ng of total RNA has been used to check the expression of miRNAs.

SYBR green Assay System was used for mRNA, lncRNA and miRNA detection and quantification. We have used actin as an endogenous control for mRNA and 5SrRNA as an endogenous control for miRNAs. The thermocycling conditions for SYBR green Assay system include 1 cycle of 95°C for 10 min, 40 cycles of 95°C for 15 s, 60°C for 30 s and 72°C for 30 s (Applied Biosystems). $2^{-\Delta\Delta Ct}$ method algorithm was used to analyze the relative changes in expressions, where actin/5S served as an endogenous control. The fold change was calculated using $2^{-\Delta Ct}$. ΔCt = Ct (target gene) −Ct (endogenous control) and ΔΔCt = ΔCt (target sample) −ΔCt (control sample). Melting curve analysis of every (q)PCR was conducted after each cycle.

**Luciferase Assay**

According to the manufacturer's protocol, Firefly luciferase activity was measured using Dual-Luciferase Reporter Assay System (Promega, USA Cat#1910). The transfected cells were harvested in Passive lysis buffer (PLB) after 48 hours of transfection, and luciferase activity was measured.
Cell cycle Analysis

HCT116-/- cells were transfected with miR-4671-5p or miR-34a-5p overexpression construct 48 h post-transfection; the cells were harvested and fixed with methanol. The fixed cells were treated with RNase A (10 mg/ml) for 1 h at 37°C, following which PI (Propidium iodide-1mg/ml) was added to the cells and taken for Flow cytometric analysis.

Bioinformatic Analysis

dbDEMC2.0 (https://www.biosino.org/dbDEMC/index) has been used to perform a meta-profiling of selected miRNAs (24). TargetScan 7.2 (https://www.targetscan.org/vert_72/) has been used to predict target mRNAs of miRNAs (25). miRDB has been used to predict target miRNAs (https://mirdb.org/cgi-bin/search.cgi) (26,27). GO-term analysis was done on PANTHER release 17.0 (http://www.pantherdb.org/). Kaplan-Meier survival analysis was done on R2: Genomics Analysis and Visualization Platform (http://r2.amc.nl). Heat map for Figure 1E has been generated using Heatmapper (http://heatmapper.ca/).

Statistical analysis

The data for the experimental section are expressed as mean ± SD. Statistical significance for the experiments was determined using two-tailed Student's t-test. The criterion for statistical significance was $p \leq 0.05$ (*) or $p \leq 0.01$ (**) or $p \leq 0.001$(***)

RESULTS

Small RNA sequencing reveals miRNA targets of p53 and $\Delta 40p53$

H1299 cells (that do not endogenously express any p53 isoforms), were transfected with vectors (in triplicate) to ensure that they expressed only FLp53, only $\Delta 40p53$, both p53 and $\Delta 40p53$ (vector 14A), or GFP (Control, C) (Figure 1A-C). We then investigated the effect of differential expression of p53 isoforms on miRNA gene expression using RNA isolated from these cells and processed for quality control and sequencing of small RNAs. A heatmap was generated for those miRNAs with unidirectional fold changes for at least one condition of p53 isoform overexpression, in all triplicates, compared to control (Figure 1D). Among 135 miRNAs, we selected a significantly expressed cluster which is differentially regulated under at least one condition. ($p \leq 0.05$; Figure 1E).
We primarily aimed to identify miRNAs with an expression that was differentially regulated by p53 and Δ40p53 and thus selected miR-4671-5p, miR-301b-5p, miR-34a-5p, and miR-548ae-5p, with fold changes ranging between ≥ 0.58 and < −1.0 (p ≤ 0.05). The expression of miR-4671-5p was significantly downregulated and was unchanged on the Δ40p53 and p53 backgrounds, respectively. The expression miR-301b-5p was significantly downregulated and unchanged on the p53 and Δ40p53 backgrounds, respectively. We also analysed the novel miR-548ae-5p, the expression of which was significantly upregulated by p53 and the other two conditions. We then investigated the mechanism of co-regulation by the isoforms (if any) on miR-548ae-5p, and the positive control was miR-34a-5p that is regulated by p53 (28).

Selection and validation of miRNAs for further studies

Control (vector only), p53, Δ40p53, and 14A (a combination of both isoforms) were transfected in H1299 cells (Figure 2A) and the miRNA levels were examined using qRT-PCR. The expression of miR-4671-5p decreased when Δ40p53 and 14A were overexpressed and remained unchanged upon p53 overexpression compared with controls (Figure 2B). The expression of miR-34a-5p and miR-548ae-5p increased when p53, Δ40p53, and 14A were overexpressed (Figure 2C and D). The expression of miR-301b-5p was not altered by overexpressed p53, whereas overexpressed Δ40p53 and 14A increased it (Figure 2E). Except for miR-301b-5p, the expression of miR-4671-5p, miR-548ae-5p, and miR-34a-5p was similar to that obtained using the sequencing platform (Figure 2F). Therefore, we continued our investigation with these three miRNAs.

Regulation of miRNAs by Δ40p53 and p53

Colon cancer cell lines HCT116+/+ (predominantly expressing p53 and some Δ40p53) and HCT116-/− (expressing only 40p53) were used to determine how p53 isoforms regulate the expression of these miRNAs and to render our study more physiologically relevant (Figure 3A). We initially found less endogenous expression of miR-4671-5p and more miR-548ae-5p and miR-34a-5p in HCT116-/−, than HCT116+/+ cells (Figure 3B). Furthermore, p53 or Δ40p53 was partially silenced by siRNA-mediated knockdown in HCT116+/+ (Figure 3D) and HCT116-/− (Figure 3F) cells and miRNA levels were detected using qRT-PCR. The expression of miR-548ae-5p and miR-34a-5p significantly decreased upon silencing p53 or Δ40p53 in HCT116+/+ cells, whereas that of miR-4671-5p did not significantly change (Figure 3 C). Silencing Δ40p53 increased miR-4671-5p and decreased miR-548ae-5p and miR-34a-5p expression in HCT116-/−cells. These data suggested that Δ40p53 regulates miR-
4671-5p negatively and miR-548ae-5p and miR-34a-5p positively (Figure 3E). Importantly, Δ40p53 exclusively altered miR-4671-5p expression, with no effect by FLp53. These results also indicated that changing relative p53 and Δ40p53 levels differentially affects miRNA expression. The abundance of p53 isoforms notably differs among various types of cancer (6). Therefore, target miRNAs should vary accordingly.

Bioinformatic analysis of miR-4671-5p, miR-548ae-5p, and miR-34a-5p expression in various types of cancer using the database of differentially expressed miRNAs (dbDEMC) 2.0 revealed that miR-34a-5p is expressed in many types of cancer, whereas miR-4671-5p is expressed only in colon, lung, and pancreatic cancers. In contrast, miR-548ae-5p was not detected in any cancer databases (Figure 4A). The results indicated that the varying levels of miRNAs among types of cancer could be attributed to the varying abundance of p53 and Δ40p53. To confirm this, we overexpressed p53 or Δ40p53 at different ratios in H1299 cells and measured the expression of these miRNAs (Figure 4B). We found that miRNA expression significantly changed according to the abundance of p53 or Δ40p53. The expression of miR-34a-5p was upregulated by either overexpressed p53 or Δ40p53. However, different ratios of both p53 and Δ40p53 isoforms decreased miR-34a-5p expression, whereas equal amounts did not cause any changes (Figure 4C). These results agree with previous findings suggesting that p53 and Δ40p53 co-regulate their activities, thus leading to the modulation of target gene expression (12).

Furthermore, overexpressed FLp53 did not significantly change miR-4671-5p expression, which was (similar to our findings in Figure 2A). However, increasing Δ40p53 levels in the absence or presence of FLp53 consistently decreased miRNA expression (Figure 4D). The combined effects of these isoforms on the expression miR-4671-5p and 14A were similar. Thus, in the context of miR-4671-5p, p53 might act as a regulator of the Δ40p53-mediated gene expression. However, p53 alone did not affect miR-4671-5p.

Effect of miR-4671-5p on its target mRNAs

Micro RNAs function by base pairing with their target mRNAs and negatively regulating their expression. The miR-34a family is regulated by p53 and miR-34a-5p is involved in multiple cellular processes (28). However, miR-4671-5p is novel, and its regulation has remained unknown. Therefore, we investigated miR-4671-5p and elucidated its downstream functions using the online databases Human TargetScan 7.2 and miRDB to identify potential
mRNA targets of miR-4671-5p. These two databases respectively provided 780 and 46 targets (Figure S1, Table 1). 40/46 targets from miRDB targets were found in the TargetScan database and 6/46 were absent. Next, we performed GO term analysis by PANTHER statistical overrepresentation test using the curated 786 unique-target gene. GO molecular function “protein serine kinase activity” was significantly enriched in the predicted target list of miR-4671-5p that includes multiple kinases (Figure S1, Table 2).

CDK11B (Cyclin Dependent Kinase 11B) and CDK5R1 (Cyclin Dependent Kinase 5 Regulatory Subunit 1) were selected as potential miR-4671-5p targets (Figure 5A). Importantly, PANTHER analysis showed an overrepresentation of serine kinases as predicted targets of miR-4671-5p, highlighting the relevance of selecting these candidates (Figure S1, Table 2). Further, we also shortlisted SGSH (N-Sulfoglucoasamine Sulfohydrolase) as it is the topmost target for miR-4671-5p in Targetsacn. Mutations in SGSH cause a lysosomal sulfite enzyme deficiency that leads to glycosaminoglycan (GAG) and heparan sulfate accumulation in various organs of the body, ultimately causing mucopolysaccharidosis III A (MPS) syndrome that is characterized by severe neurological symptoms and skeletal deformities (29). A role for SGSH in cancer is yet unknown. An analysis of existing primary tumor datasets for SGSH gene expression revealed that low SGSH is significantly correlated with poor survival in pancreatic adenocarcinoma (Figure 5B, Table 3) in 3/4 datasets, while high SGSH is significantly correlated with poor survival in multiple colon tumor datasets (Figure 5C). Importantly, in these tumor types, prognostic SGSH levels trend opposite to miR-4671-5p as revealed in dbDEMC2.0 analysis (Figure 4A) suggestive of a link between the miRNA and mRNA. Thus, SGSH, CDK11B and CDK5R1 were selected for further studies.

We validated miR-4671-5p target levels under the same experimental conditions as in Figure 4B, with different ratios of overexpressed p53/Δ40p53 in H1299 cells. The results showed increased SGSH, CDK11B, and CDK5R1 levels only under Δ40p53 overexpression (Figure 5D-F). Moreover, we also checked for the protein levels of these targets in HCT116-/- (with endogenous expression of Δ40p53), we observe that the abundance of SGSH, CDK11B and CDK5R1 was very high compared to HCT116+/+ (Figure 5G). This observation was in line with Figure 3A, where miR-4671-5p levels were lower in HCT116-/- than in HCT116+/+. This contrasting regulation of miR-4671-5p and its targets mediated by the presence of Δ40p53 confirmed the involvement of these molecules in a single pathway.
To confirm the regulation of target mRNAs by Δ40p53, we partially silenced Δ40p53 in HCT116-/- and miR-4671-5p target mRNA expression mediated by siRNA. The results showed that SGSH, CDK11B and CDK5R1 mRNA expression significantly decreased under silenced Δ40p53 (Figure 5H, I). These findings confirmed that Δ40p53 positively regulates SGSH, CDK11B, and CDK5R1 mRNA expression. The Δ40p53-mediated positive regulation of mRNAs was directed via downregulated miR-4671-5p expression (Figure 2A). We overexpressed miR-4671-5p in HCT116 -/- cells to determine the direct effects of miRNAs on their targets. The expression of SGSH, CDK11B and CDK5R1 mRNAs was decreased (Figure 5J, K) and the effect was the most significant on SGSH mRNA.

**Cellular role of miR-4671-5p and target-mRNA interaction**

Further, the direct binding experiment was performed using luciferase constructs to establish a direct link between miR-4671 and its targets. 3'UTRs of CDK5R1 and SGSH containing miR-4671 binding sites were cloned in luciferase constructs. Following this, mutations were generated in the 3'UTRs at miR-4671-5p binding sites (Figure 6 A, B). HCT116-/- cells were transfected with CDK5R1 and SGSH 3'UTR WT and mutants in the background of miR-4671-5p overexpression. The overexpression of miR-4671-5p decreased the luciferase activity as compared to the control. Additionally, when the miR-4671-5p binding site was mutated in the 3'UTRs, the inhibitory effect on the luciferase was rescued, resulting in increased luciferase activity (Figure 6 C, D). This result suggests that miR-4671-5p directly binds to CDK5R1 and SGSH 3'UTRs, with more significant effect observed on SGSH.

As mentioned earlier (Figure 5B-C), survival-correlated SGSH levels trend opposite to the levels of miR-4671-5p in certain cancers types, which suggests a direct possible link between the miRNA and the mRNA. However, the functional effect of mRNA is mainly mediated through its protein expression, therefore we checked the effect of siΔ40p53 or overexpression of miR-4671-5p on the respective protein levels. In both conditions, we observed a substantial and consistent reduction in SGSH protein levels reflecting the mRNA levels (Figure 6 E, F). This result suggested that SGSH mRNA could be a significant target downstream to Δ40p53-miR-4671-5p pathway. Finally, it was essential to decipher the direct role of miR-4671-5p on any cellular process. Since most of the selected targets of miR-4671-5p were directed toward cell cycle regulation, we checked for the changes in cell cycle phases upon miR-4671-5p overexpression. We observed that the percentage of cells in the S phase were significantly increased, whereas the number of cells in the G2 phase decreased (Figure...
indicating the activation of a potential S-phase checkpoint which accumulated the cells in the S phase and prevented them from proceeding to G2. Thus, miR-4671-5p can regulate the cell cycle and possibly other associated cellular processes.

**DISCUSSION**

MicroRNAs regulate diverse cellular processes, including embryonic development, cell cycle, proliferation, and survival. Cancer is often associated with changes in miRNA expression (30). Several studies have identified p53-regulated miRNAs and their roles in cancer (31). Common malignancies express different p53 isoforms (6). However, miRNA regulation by p53 isoforms had remained unknown until recently, and we showed that Δ40p53 specifically upregulates miR-186-5p and downregulates expression of the oncogene YY1, leading to a decrease in cell proliferation (23). The function(s) of Δ40p53 has not been studied in detail, although its importance has been acknowledged given its roles in cellular functions such as apoptosis, cell cycle regulation, senescence, migration, and invasion (8). If Δ40p53 is an important regulatory molecule, the pertinent question is which cellular pool of RNAs, specifically long non-coding (Inc) and microRNAs, are regulated. This has gained increasing importance in many areas of research.

Here, we identified several miRNAs of which their expression is regulated by Δ40p53, either differentially or to the same extent as p53. We then assessed the role of miR-4671-5p in cellular processes, as it was regulated exclusively by Δ40p53. Overexpressed Δ40p53 decreased, whereas p53 did not change expression of the novel miR-4671-5p. However, overexpressed 14A (combination of Δ40p53 and p53) decreased in miR-4671-5p expression, indicating that p53 facilitates the Δ40p53-mediated regulation of miR-4671-5p (Figure 2B). Likewise, different ratios of p53 and Δ40p53 reduced miR-4671-5p under all conditions where both isoforms were present (Figure 4D). This indicated that a differential abundance of p53 and Δ40p53 expression in cancer will accordingly lead to variable expression of downstream targets. To characterize the role of miR-4671-5p. We identified potential mRNA targets using bioinformatic analysis (Figure S1) and selected a unique target, SGSH, that plays a metabolic role in governing cellular function. We report possible prognostic value of SGSH gene expression in certain tumor types (Figure 5B-C); miR-4671-5p levels trend oppositely in these cancer types (Figure 4A). High SGSH expression was also significantly correlated with poor survival in glioblastoma multiforme (GBM), a highly malignant adult
brain tumor (Figure S1, Table 3). In addition, high hsa-miR-4671-5p is correlated with poor
survival in a miRNA expression dataset in neuroblastoma, a common pediatric tumor, while
low SGSH levels are significantly correlated with poor survival in multiple neuroblastoma
gene expression datasets (Figure S1, Table 3), providing further evidence of a putative link
between the two. While the prognostic value of SGSH is significant, the seemingly
confounding directionality in survival-correlation (high levels correlated to better survival in
pancreatic adenocarcinoma and neuroblastoma versus low levels, in colon tumor and GBM)
hints that SGSH is not a bona fide proto-oncogene or tumor suppressor; rather such
differences may be explained by unique cancer-specific adaptation programs modifying
Δ40p53-miR-4671-5p-SGSH axis that requires further investigation. Further, from
enrichment analysis, we selected CDK11B and CDK5R1 as potential targets. We found that
overexpressed Δ40p53 increased the abundance of all targets (Figure 5D-F), the proteins also
have a higher abundance in the presence of endogenous Δ40p53 (Figure 5G). Although miR-
4671-5p expression was decreased by co-expressed Δ40p53 and FLp53 (Figure 4D), this
trend was not apparent at the target mRNA level (Figure 5D-F). This might stem from the
activated or deactivated expression of other miRNA by combined p53 isoforms, which in turn
would influence target mRNA regulation by miR-4671-5p. We then determined the relevance
of the Δ40p53-miR4671-5p-mRNA axis. Target mRNA expression was directly decreased by
overexpressed miRNA and silenced Δ40p53 (Figure 5H and K), confirming a link between
them. Figure 6A-D shows mutant experiments with SGSH and CDK5R1 3’UTRs which
established a direct link between miR-4671-5p and mRNAs. Our finding that Δ40p53, but not
FLp53 regulated the miR-4671-5p–SGSH axis suggests the biological significance of Δ40p53
to metabolic regulation.

We measured protein levels of target mRNAs to determine the cellular effects of interactions.
Direct miRNA overexpression and silenced Δ40p53 decreased SGSH protein levels (Figure
6E, F). We assessed the physiological relevance of SGSH and miRNA interactions before
delving into the cellular effects of this regulation. The SGSH encodes a sulfamidase enzyme
associated with the lysosomal degradation of heparan sulfate, a glycosaminoglycan.
Mutations in SGSH cause impaired degradation of heparan sulfate in MPS Type IIIA (32,33).
How GAGs affect the cell cycle, a complex process that controls cell growth and division, in
MPS disorders has been investigated. Flow cytometry findings have revealed disturbed cell
cycle in all MPS types (34). These findings suggest that SGSH is directly involved in cell
cycle regulation. Along with SGSH, other targets of miR-4671-5p, namely CDK11B and CDK5R1 are also associated with cell cycle regulation.

Therefore, we directly examined whether miR-4671-5p mediates cell cycle effects on different cell cycle phases. Upon miR-4671-5p overexpression, the ratios (%) of cells respectively increased and decreased in the S and G2 phases (Figure 6G). The increased abundance of S-phase cells may be attributed to cell cycle arrest in the intra-S phase. While this is expected from regulation impinging on CDK5R1 and CDK11B (Figure 7), the effect of SGSH on cell cycle has been relatively obscure. Populations in the S and G2 phases are respectively increased and decreased in MPS Type IIIA, where SGSH is mutated (34). Heparan sulfate inhibits topoisomerase 1 activity during DNA replication (35), and blocking this activity causes cell cycle arrest at the intra-S phase (36). Thus, the inhibition of SGSH expression by miR-4671-5p, apart from inhibiting cell-cycle regulatory kinase functions, might increase the heparan sulfate content in cells, combinatorically causing an increase in S-phase cell counts (intra-S-phase arrest). Thus, ∆40p53 under physiological conditions decreases miR-4671-5p expression, which leads to increased SGSH levels that help to maintain metabolic and cellular homeostasis (Figure 7).

ACKNOWLEDGEMENTS

We are grateful to Prof. J.C. Bourdon, University of Dundee, UK and Dr. Robin Fahraeus, INSERM, France, for providing us with the anti-p53 antibody. We want to acknowledge NIBMG (National Institute of Biomedical Genomics, Kalyani, WB, India) for providing an RNA sequencing facility. We also thank the present and past SD lab members for their helpful discussion of the work. A research grant supports this work to SD from the Department of Biotechnology (DBT), Govt. of India. SD also acknowledges the J.C. Bose fellowship for research support. The DBT-IISc partnership program also supported this study. DST Fund for Improvement of Science and Technology Infrastructure (FIST) level II infrastructure and University Grants Commission Centre of Advanced Studies support is acknowledged.

AUTHOR CONTRIBUTIONS

AP and SD: Conception and design of studies analysis, interpretation, and article writing. AP, SKT and PKG for performing the experiments, interpretation of the results and article
editing. DK for bioinformatic analysis, interpretation of results, article writing and editing.

SG, SP and AM for RNA sequencing and its analysis.

DATA AVAILABILITY STATEMENT

The sequencing data files obtained is available in the online biorepository forum with the SRP BioProject ID PRJEB47067.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

Figure 7: Graphical Abstract: Model depicting the regulation of Δ40p53 mediated regulation of miR-4671-5p and their impact on cell cycle

(A) In the absence of Δ40p53, miR-4671-5p levels do not decrease, leading to increased target mRNA degradation. The residual mRNAs give rise to decreased proteins (e.g. SGSH), leading to Intra-S phase cell cycle arrest. The mechanism of arrest could be due to impaired degradation of Heparan Sulphate (HS) by SGSH, causing HS accumulation, thereby destabilizing the metabolic and cellular homeostasis. (B) However, when Δ40p53 is present, it decreases miR-4671-5p levels, preventing target mRNA degradation. The increase in residual mRNAs gives rise to more proteins (e.g., SGSH), which allows regular cell cycle propagation. Here the mechanism could be increased degradation of HS, which helps to stabilize the metabolic and cellular homeostasis.

Figure S1: (Table 1): miR-4671-5p targets obtained from TargetScan 7.2 database and miRDB. (Table 2): Result of PANTHER Statistical Overrepresentation Test of “GO molecular function”-terms obtained from 786 predicted miR-4671-5p targets, using all Homo sapiens genes as reference list. FDR: False Discovery Rate. Results for FDR P < 0.05 reported. (Table 3): Survival analysis of patients as classified by SGSH mRNA expression levels in pancreatic adenocarcinoma, colon tumor, glioblastoma and neuroblastoma gene expression datasets available on R2: Genomics Analysis and Visualization Platform. p-values <0.07 reported, below 0.05 considered significant. Similar analysis for hsa-miR-4671-5p expression, as available in the sole miRNA expression dataset on R2.
