## SUMMARY

T-Cell Factors (TCFs) are the main transcriptional effectors of $\mathrm{Wnt} / \beta$-catenin signaling. TCF responsiveness is a hallmark of self-renewal in mouse embryonic, and adult, neural stem cells (NSC). However, in vivo contribution(s) of TCF activities in long-lived NSCs are poorly understood. Granule neuron progenitors (GNP) in the upper rhombic lip (URL) are long-lived NSCs which express Atoh1 and generate cerebellar granule neurons. Using functional and transcriptomic approaches in amphibian, we demonstrate that TCFs are active in the URL, and are strictly necessary for the emergence and maintenance of the GNP germinative zone. We identify BarH-like 1 (Barhl1), a direct target of Atoh1, as a gate keeper for GNP exit from the URL, through silencing of TCF transcriptional activity. Our transcriptomic and in silico analysis identifies Barhl1/TCF URL target genes, and confirms our functional data. Our study provides in vivo evidence that inhibition of TCF repressive activity is necessary for maintenance of the URL, a long-lived neural germinative niche.

## KEYWORDS

Granule Neuron Progenitors, Cerebellum, Upper Rhombic Lip, Neural Stem Cell, Germinative niche, Wnt signaling, TCF/Lef, BarH-like 1.

## INTRODUCTION

The Wnt/ß-catenin cell-to-cell signaling pathway coordinates development and is one of the most conserved in the animal kingdom. The large majority of Wnt/ $\beta$-catenin transcriptional targets are regulated by T-Cell Factor/Lymphoid Enhancer-binding Factor (TCF/LEF) transcription factors (TF) ${ }^{1,2, \text { reviewed in } 3}$. Investigation of the developmental fate of $\mathrm{Wnt} / \beta$-cateninresponsive cells in embryonic and postnatal mouse brains reveals that long-lived NSCs retain neuroepithelial properties, and $\mathrm{Wnt} / \beta$-catenin responsiveness throughout development ${ }^{4}$. In the adult mouse ventricular-subventricular zone of the lateral ventricles, WNT signaling promotes both NSC self-renewal and neural progenitor cell proliferation, while TCF/LEF activity is detected in deeply quiescent NSC cells ${ }^{4-7}$ reviewed in 8 . Moreover, hippocampal quiescent NSC and progenitors in culture exhibit enhanced TCF/LEF1 driven transcription ${ }^{9}$. Taken together, these observations suggest contribution(s) of Wnt driven TCF transcriptional activity in adult NSC biology. However, currently, our understanding of such activities in longlived NSC remains surprisingly fragmented ${ }^{8, \text { reviewed in } 10-12}$.
A crucial component of the central nervous system (CNS) in all jawed vertebrates is the cerebellum, involved in executing motor functions as well as participating in higher cognitive processes such as decision-making, emotional and social behaviour, and expectation of reward ${ }^{13-15}$. The cerebellum has two major stem cell niches: the ventricular zone (VZ) adjacent to the fourth ventricle, which produces all cerebellar GABAergic inhibitory neurons ${ }^{16-18}$; and the upper rhombic lip (URL) which is the origin of glutamatergic excitatory neurons, derived from Atonal homologue 1 (Atoh1)-expressing progenitors. The URL gives birth first to the deep cerebellar nuclei (DCN), followed by the unipolar brush cells (UBC) and the granular neuron progenitors (GNP) that in turn produce granule neurons, the predominant neuronal population in the entire CNS reviewed in 19-21.
While the VZ appears to be TCF inactive, positive TCF transcriptional activity has been documented in the URL of mice, human and Xenopus species ${ }^{22-25}$. Moreover, in vitro and in vivo studies in mice show that, in contrast to what is observed in NSC and progenitors of the developing CNS, or in the $\mathrm{VZ}^{26,27}$, constitutive activation of $\beta$-catenin in Atoh1+ URL cells does not promote their proliferation ${ }^{26,28-30}$. Taken together, these data indicate that TCF-mediated transcription probably contributes to the URL biology, but its role(s) in this germinative area remains undefined. In addition, they highlight the presence of TCF developmental regulators within this germinative area that have not yet been identified.
The GNP developmental path is marked by expression of specific TF, including ATOH1 which is indispensable for maintaining GNP in an immature state ${ }^{31}$. In amniotes, Atoh1 expression initiates in the RL, is maintained in the EGL during GNP proliferation, and is lost in differentiated GN that start expressing the basic Helix Loop Helix (bHLH) neurogenic differentiation factor 1 (Neurod1). In addition, the Paired box protein 6 (Pax6) and BarH-like 1 homeobox protein (Barhl1) expressions are markers of GNP commitment ${ }^{25,32-36}$.
Amphibians show a marked development of the cerebellum that displays morphological features resembling those found in higher vertebrates ${ }^{37,38}$ reviewed in 39,40 . The few studies performed in the amphibian Xenopus pre-metamorphosis reveal the presence of an EGL-like structure that is unique compared with other anamniotes. However, unlike in higher vertebrates, the Xenopus EGL lacks any cells that undergo proliferation ${ }^{41}$. These studies also indicate that the developmental processes that lead to the formation of GN, specifically the presence of an Atoh1-expressing URL and EGL, and the expression of Neurod1 are close to those described in higher vertebrates ${ }^{41,42}$. Of Note, the amphibian URL maintains itself until
post-metamorphic stages ${ }^{38,41}$. However, early developmental events leading to GNP induction and EGL formation have not been described in amphibians.
ATOH1 directly induces its own expression as well as the expression of the two homeodomain (HD)-containing TF, BARHL1 and BARHL2, which are mammalian homologues of the Drosophila Bar-class HD, BarH1 and BarH2 ${ }^{43-46}$ reviewed in 3,47 . In mice, Barh11 cerebellar expression is detected in committed GNP, and persists in the EGL ${ }^{33,48}$. In the developing cerebellum, BARHL1 participates in the generation of the EGL ${ }^{45}$, and is one of the major TF that regulate the radial migration of GNP in a mechanism involving Neurotrophin3 (NT3) ${ }^{49}$. Furthermore, an impairment in GN survival, and an attenuated cerebellar foliation, are observed in Barhl1-/- mice ${ }^{50}$. On the other hand, we established that BARHL2 dramatically enhances the transcriptional repressor activity of TCF, and prevents $\beta$-catenin driven activation of TCF target genes ${ }^{51,52}$. Immunoprecipitation assays reveal physical interaction between BARHL2 and the two transcriptional repressors of Wnt target genes TCF7L1 and Groucho/Transducin-like Enhancer of Split (Gro/TLE) ${ }^{52}$. However, the role of BARHL2 in cerebellar development has not been investigated, and whether BARHL1 similarly interacts with, and regulates, TCF transcriptional activity is unknown.
Here, we investigated the role of both Tcf transcriptional activity, and Barhl1, in GNP development using Xenopus as a model system. We establish that markers of GN early progenitors, EGL, commitment, and differentiation, are conserved in Xenopus compared to amniotes. Using gain and loss of function experiments (GOF/LOF), immunoprecipitation, and a $X$. tropicalis Wnt reporter transgenic line, we demonstrate that Tcf-mediated transcriptional activation is strictly necessary for both the emergence and maintenance of the cerebellar URL, and furthermore demonstrate that, in this germinative area, Barhl1 is the main repressor of Tcf transcriptional activity. Barhl1 LOF, through Morpholino (MO)-mediated depletion or Crispr/Cas9 gene knock-out, dramatically increases Tcf transcriptional activity in the URL, leading to a major enlargement of the URL, and significant delays in GNP differentiation. Using a transcriptomic approach, we confirm our functional assays and identify direct and indirect target genes repressed by Barhl1 in the cerebellar URL. Indeed, Barhl1 depletion induces an upregulation of TF involved in maintenance of neural stem/progenitor properties, an enhancement of both $\mathrm{Wnt} / \mathrm{Tcf}$ and Notch signaling activities, associated with a down regulation of genes involved in inhibiting proliferation, and promoting neural differentiation. Together with in silico analysis of Barhl1 target genes regulatory regions, our study confirms that in the amphibian, Barhl1 drives URL stem/progenitor cells out of their germinative niche, towards commitment and differentiation, by repressing TCF transcriptional activity.

## RESULTS

## Spatial and temporal expression of key markers of GNP development are conserved in Xenopus compared to higher vertebrate

We performed in situ hybridization (ISH) on $X$. laevis tadpoles through pre-metamorphic froglets (stages 35 to 50 ) and assessed the expression patterns of genes known to be involved in the development of Atoh1 lineage in rodents, focusing on GN. By using atoh1 to label the URL and EGL, pax6 and barhl1 to mark GNP commitment, and neurod1 to mark post-mitotic GN, we established a fate map that outlines the developmental progression of atoh1 lineage cells within rhombomere 1 (R1), located caudal to the midbrain-hindbrain boundary (MHB). The proliferation marker n-myc helps define the posterior boundary of R1 (Fig. 1A; Fig. S1B).

We found that pax6 expression begins at stage 38 (Fig. S1C), while barh/1 expression begins at stage 39-40 (Fig. 1F), which we used as a landmark of GNP induction. From stage 38 to stage 48, atoh1 is expressed in the URL and in a layer of 3 to 4 cells bordering the URL, which we consider to be the EGL (Fig. 1B; Fig. S.1A). Although the $n$-myc expression pattern is similar to that of atoh1 in the URL, $n$-myc is also strongly detected in the VZ, in agreement with its expression in proliferating cells (Fig. 1C, Fig. S1B).
We investigated the dynamics of pax6, barhl1, and neurod1 expressions within R1 from stage 38 to stage 48 (Fig. 1E-G; Fig. S1C-E). All markers are present in the cerebellar primordium and are first detected in the caudal region of the EGL. During this developmental period, cells expressing barhl1 and neurod1 migrate from an external layer partially covering the cerebellar plate towards the inner cerebellar tissue, where they undergo their final differentiation (Fig. 1F, G, Fig. S1D, E). Furthermore, while Orthodenticle Homeobox 2 (otx2) expression is typically limited to the posterior lobes of the EGL in amniotes, we detected otx2 expression in the caudal EGL at stage 39, which was subsequently restricted to the cerebellar plate (Fig. 1D). At stage 48, Hairy and enhancer of split-4 (hes4), a known marker of Notch-active cells and of stemness in Xenopus ${ }^{53,54}$, strongly labels both the VZ and the EGL at stage 48 (Fig. 1H). hes4 is not expressed in mice, while its expression is found in Xenopus and in Human. Additionally, we did not observe expression of barhl2 in the cerebellar anlage at the analysed developmental stages (Fig. S1F).
These observations indicate striking similarities in GNP development between Xenopus and amniotes. Specifically, the expression pattern of genes involved in induction and specification of GNP, including atoh1, n-myc, pax6, barhl1, otx2, neurod1, is conserved. As previously reported ${ }^{41}$, we detect the presence of an EGL along the R1 antero-posterior axis marked by atoh1 and hes4. Our observations also indicate a gradient in GNP differentiation, initiated in the caudal EGL at stage 38 and progressing to the rostral part up to stage 50 . Starting at stage 50 , we report changes in the shape of the URL. Thus, we focused our analysis on cerebellar anlage development between stage 38 and stage 48.

## In the cerebellar primordium, constitutive Tcf inhibition and Barhl1 overexpression produce similar developmental defects in atoh1 expression, URL induction and GNP early commitment/differentiation

We focused our study on the role of Tcf and Barhl1 in URL establishment and maintenance, during the time window where GNP are produced. We used tcf7l1- $\Delta \beta$ cat-GR, a previously described inducible form of $t c f 7 / 1$ which lacks its $\beta$-catenin binding domain, and thus acts as a dominant negative and constitutive inhibitor of Tcf transcriptional activity ${ }^{55}$ (Fig. S2). Development of the URL and GNP was investigated using either atoh1, or pax6, barhl1 and neurod1 as respectively URL/EGL, and GNP commitment /differentiation markers.
At a high dose, tcf7/1- $\Delta \beta$ cat-GR overexpression induced a dramatic reduction in the size of the URL, associated with the disappearance of the expression of its key marker atoh1. Of note, this effect is restricted to the R1 (Fig. 2Aa-a", c). At a lower dose, tcf7/1- $\Delta \beta$ cat-GR overexpression induced a decrease in atoh1 expression (Fig. 2Ab, c). This decrease is associated with both an increase of expression, and a rostral shift, observed with the three commitment/differentiation markers pax6, barhl1, and neurod1 within the R1 (Fig.2Ba-c). tcf7l1- $\Delta \beta$ cat-GR effects on atoh1, pax6, barhl1 and neurod1 expression were quantified (Fig.2Ac-Bd).
In amniotes, BARHL1 is a direct target of ATOH1 ${ }^{45,46}$. We next asked whether Barhl1 overexpression impacts early development of the URL and GNP (Fig. S2). We observed that
barh/1 overexpression phenocopies that of Tcf inhibition. We observed a strong decrease in atoh1 transcripts levels within the URL (Fig. 2Ca-a", d). Loss of atoh1 and the URL is associated with an increase of pax6 and neurod1 expression, and a concomitant rostral shift in both markers' expression within R1 (Fig. 2Cb-d).
Our data indicate that Tcf transcriptional activity is strictly necessary for the expression of atoh1 within the URL, and that inhibiting Tcf activity leads to accelerated GNP differentiation. Similarly, overexpression of Barhl1 in the cerebellar primordium results in URL induction defects, associated with premature GNP differentiation.

## In the cerebellar URL, inhibition of Barhl1 maintains GNP in an early progenitor state

To decrease Barhl1 activity within the cerebellar anlage, we designed two morpholinos (MO), MObarhl1-1 and MObarhl1-2, specifically targeting Xenopus barhl1 mRNA (Fig. S2; S3; Methods). We investigated whether, andby what mechanism(s), Barhl1 Knock-Down (KD) affects the development of the URL, the EGL, and/or GNP development. At stage 42, 45, and 48, depletion of Barhl1 induced an increase in atoh1 expression. We observed atoh1 expressing cells spreading across the surface of the cerebellar plate (Fig. 3Aa-a", Ba-a"; Fig. S3B, C, D). This ectopic expansion within the URL and to the EGL is associated with a major decrease in pax6 expression (Fig. 3Ab, Bb; Fig. S3B, D). Both MO induced the same phenotype, which was quantified (Fig. 3C). At stage 42, the increase in atoh1 expression in Barhl1-KD embryos is corroborated by a similar increase in n-myc expression (Fig. S3C). We further tested the ability of mbarhl1-GR to rescue the Barhl1-KD phenotype. mbarhl1-GR was co-injected with MObarhl1-1, and neurod1 was used as a marker of GNP differentiation. MObarhl1-1 and MObarhl1-2 induced a strong decrease in neurod1 expression, which was rescued by co-injection of mbarh/1-GR (Fig. 3D).
We next asked whether inhibition of Tcf activity compensates for Barhl1-KD using pax6 as a marker of GNP commitment. As previously observed, Barhl1-KD delayed GNP differentiation process, while tcf7l1- $\Delta \beta$ cat-GR overexpression accelerated it (Fig. 3Ea-c). MObarhl1-1 coinjected with two different doses of tcf7l1- $\Delta \beta$ cat-GR mRNA rescued the phenotype (Fig. 3Edf).

These data provide strong evidence that MObarhl1 acts by specifically inhibiting endogenous Xenopus Barhl1 activity. They also indicate that Barhl1 depletion delays differentiation of GNP. Combined, these observations reveal that Barhl1 and Tcf act in opposing ways within the URL and the EGL, and maintain GNP in an early progenitor state.

## Barhl1 limits Tcf transcriptional activity within the cerebellar primordium

We next asked whether Barhl1 directly controls Tcf transcriptional activity within the cerebellar URL. We investigated interactions between Barhl1, Gro4, and Tcf7l1, by performing coimmunoprecipitation (Co-IP) experiments on protein extracts from HEK293T cells transfected with tagged constructs of Tcf711, Gro4, and Barhl1 (Fig. 4A; Fig. S2). In agreement with Barhl1 containing two Engrailed Homology-1 (EH1) motifs known to interact with the WD-repeat domain of Gro, Barhl1 co-immuno-precipitated with Gro4 (Fig. 4Aa). Using Tcf7l1 as bait, we further observed that Tcf711 could immuno-precipitate Barhl1, in the presence and absence of Gro4. The presence of Barhl1 does not affect the interaction of Tcf7l1 with Gro4 (Fig. 4Ab). Concatemers of the consensus Tcf binding motif have been used to generate Wnt/Tcf reporter lines, such as Xenopus tropicalis (X. tropicalis) transgenic pbin7LefdGFP line ${ }^{22,56,57}$, which contains one copy of a wnt reporter gene. We assessed Tcf activity from stage 42 up to stage

50 using this reporter line and observed a positive Tcf activity in the URL. Contrastingly, we did not detect any Tcf activity in the VZ and the EGL at similar developmental stages. Importantly, up to stage 48 we observed that Tcf activity is stronger at the rostral end of the URL. This asymmetry of expression is lost at stage 50 (Fig. 4Ba-d). In addition, we observed a strong correlation between Tcf activity and atoh1 expression (Fig. 4Ba'-d'), which appears to be complementary to that of barhl1 (Fig. 4Bc", c"'-d"). Taken together, these data are consistent with our previous observations indicating that Tcf activity is strictly necessary for the induction of atoh1 expression within the URL.
We next assessed the impact of Barhl1 gain of function (GOF) and loss of function (LOF) on Tcf activity (Fig. 4C). Whereas mBarhl1 overexpression decreased Tcf activity (Fig. 4Ca), we observed a threefold increase in Tcf activity upon Barhl1 downregulation with MObarhl1-1 (Fig. 4 Cb ). In contrast, MOct had no effect on Tcf activity (Fig. S4A). The effect was quantified (Fig. 4 Cc ). We further inhibited Barhl1 by selective knock-out (KO) of xbarhl1 gene in the pbin7LefdGFP line (F0 generation) using Crispr/Cas9 genome editing technology (Fig. S4B). We observed that Barhl1 KO induced an average twofold increase in Tcf transcriptional activity (Fig. 4Da-c). We assessed phenotypic penetrance in Crispr/Cas9 injected embryos based on gfp expression. We observed different levels of phenotypic severities in $>70 \%$ of injected embryos, ranging from a slight increase in gfp expression observed in $\sim 20 \%$ of injected embryos to $>40 \%$ of injected embryos exhibiting strong to complete penetrance as observed by a significant increase in gfp expression in the R1 (Fig. 4d).
To determine whether Barhl1 effects were mediated through its interaction with Gro, we used and inducible form of $m$ Barhl2-EHsGR, which contains the two EH1 domains of Barhl2 (Fig. S2) and has been previously demonstrated to act as a dominant negative for Tcf repressive activity by competing for Gro binding ${ }^{52}$. Overexpression of mBarhl2EHsGR induced a phenotype similar to that of Barhl1-KD in terms of increasing the URL/EGL size at the expense of GNP commitment/differentiation (Fig. 4Ea, b; S4).
Taken together, our data establish that Barhl1 directly interacts with Tcf7l1 and Gro, limiting their transcriptional activity in the cerebellar URL.

## Through its limiting of Tcf transcriptional activity, Barhl1 allows GNP to leave their early progenitor state and exit the proliferating URL

The URL germinative zone is characterized by its proliferative state, and its bordering of the roof plate. We first asked whether the EGL is proliferative in Xenopus, and second whether the enlargement of the URL/EGL territories observed in Barhl1-KD tadpoles was corroborated with an increased proliferation in the URL and/or within the cerebellar plate. Using immunofluorescence staining for Phosphorylated-Histone H3 (PHH3), a marker of cells undergoing mitosis, counterstained with a cell nuclear marker, we measured proliferation in tadpoles injected with either MOct or MObarhl1-1 at stage 45 and 48. In agreement with previously published data ${ }^{41}$, at both stages, $\mathrm{PHH} 3+$ cells were solely detected within the URL (Fig. 5Aa). To investigate the capacity of URL-derived GNP to leave their proliferative state, and to progress along their developmental trajectory, we measured the length of the URL on the injected side compared to the control side in embryos either injected with MOct or MObarhl1-1. At stage 45 and 48, Barhl1-KD embryos exhibited a 1.2-fold lengthening of the URL on the injected side relative to the control side (Fig. 5Ac-e). Because it was morphologically easier to distinguish the URL from the VZ at stage 48, we performed our following analysis at this later developmental stage (Fig. 5Ab). At stage 48, we measured an average 2-fold increase in the number of $\mathrm{PHH} 3+$ cells on the injected side compared to the
control side (Fig. 5Ac, d, f). Moreover, we observed and quantified the presence of proliferating cells in the cerebellar plate, which is normally devoid of PHH3+ cells as observed in tadpoles injected with MOct (Fig. 5Ac, d, g). Taken together, these results confirm that in Xenopus, the EGL is non proliferative, and show that Barhl1-KD cells are compromised in their ability to leave the URL niche and become postmitotic.
We next investigated whether Tcf inhibition could counteract Barhl1-KD effect on URL extension. As previously observed, whereas Barhl1-KD induced an extension of the URL length, tcf7l1- $\Delta \beta$ cat-GR overexpression reduced it (Fig. 5Ba-c), and co-injection of MObarhl11 and tcf7l1- $\Delta \beta$ cat-GR mRNA brought back the URL size to normal (Fig. 5Bd-f).
In conclusion, Barhl1 activity as an inhibitor of Tcf transcription is strictly necessary for URL cells to exit their niche, become postmitotic and enter the EGL.

## Transcriptomic analysis of Barhl1 activity in the developing cerebellum

barhl1 starts to be significantly expressed in the developing cerebellum at stage 40. To further document Barhl1 activity, we designed an RNA-sequencing experiment allowing the identification of Barhl1 direct and indirect target genes in the early Xenopus cerebellum.
We isolated and sequenced RNA from R1 of stage 42 tadpoles previously injected at the 4 cells stage in the 2 dorsal blastomeres with MObarhl1-1, MObarhl1-2 or MOct together with gfp. Tadpoles were selected for hindbrain injection and R1 were dissected. Samples were compared through differential expression (DE) analysis. Genes with adjusted p-value (pAdj) inferior to 0.001 were selected as significant DE genes (DEG) (Table S1). Principal component analysis of these R1 samples demonstrated that they clustered by Barhl1-KD status (Fig. 6A), indicating that changes in gene transcription were consistent across different clutches. At stage 41-42 we identified 1622 and 830 genes differentially expressed between respectively MObarhl1-1 and MObarhl1-2 injected R1, compared with MOct injected R1. Amongst these DE genes 575 were common between MOs injected samples (Fig. S6B). A selection of significant upregulated (Log2FC>0.4) and downregulated (Log2FC<-0.4) genes are represented in volcano plots for both MOs (Fig. 6B). Furthermore, we generated a heatmap representing upregulated and downregulated common DEG for both MOs (Fig. 6C).
As a first approach we performed gene ontology analysis (GO) based on pAdj<0.001 DEG using the clusterProfiler algorithm ${ }^{58}$ and compared altered biological functions between both Barhl1-KD conditions (Fig. 6D). Our GO analysis reveals that the most significantly upregulated genes act as transcriptional activators when bound to DNA (Fig. 6Da). In agreement with a delay of GNP differentiation the downregulated DEG were found to be involved in axon development and axonogenesis, in addition to neuronal differentiation (Fig. 6 Db ). Indeed, our differential expression dataset reveals that genes that are the most upregulated in the MObarhl1-1 and MObarhl1-2 conditions are involved in adult neural stem cell (NSC) maintenance. For example, dmrta2 that encode for doublesex and mab-3-related transcription factor a2, also known as dmrt5, the orphan nuclear receptor subfamily 2 group E member 1 (nr2e1) commonly known as Tailless, that are upregulated with a Log2FC over 1.5. We also observed a down regulation of the Delta/Notch-like epidermal growth factor (EGF)related receptor (dner) (Log2FC $\leq-0.5$ ), which has been suggested to be a neuron-specific Notch ligand ${ }^{59}$. Indeed, dner has been suggested to inhibit neural proliferation and induce neural and glial differentiation ${ }^{60}$. We also identify Basic Helix-Loop-Helix Family Member E22 (bhlhe2), a downstream target of NEUROD1, which is strongly downregulated in Barhl1 depleted R1 (Log2FC $\leq-0.5)^{61}$.

Our functional data argue that Barhl1 mostly act through inhibition of TCF transcriptional activity. We first investigated the presence of Barhl1 Cis Regulatory Motifs (CRM) defined as CAATTAC/G and its mirror motif ${ }^{62}$, within the regulatory sequences - 5 Kb upstream or downstream of the Transcription Start Site (TSS) - of previously identified DEG common to MObarhl1-1 and MObarhl1-2 conditions. We observed that all DEG regulatory regions contain at least 2 Barhl1 CRM, 87.5\% contain 5 or more Barhl1 CRM and $40 \% 10$ or more Barhl1 CRM (Table 1A). Thereby our identified DEG appear to be Barhl1 direct target genes. To investigate which Barhl1 target genes are also regulated by TCF we similarly searched for TCF CRM defined as CTTTGAA/CTTTGAT, within the regulatory sequences of previously identified DEG common to MObarhl1-1 and MObarhl1-2 conditions (Table 1B; Fig. 6E) ${ }^{63,64}$. We observed that $76 \%$ of Barhl1 depleted DEG regulatory regions contain at least one Tcf CRM: 26\% contain one CRM, $25 \%$ contain two Tcf CRM and $25 \%$ contain three and more Tcf CRM (Fig. 6E).
Using ISH, we explored changes in two up-regulated DEG. zic3, a member of the Zinc Finger of the Cerebellum (Zic) family known to be involved in regulation of neuronal progenitor proliferation versus differentiation, and cerebellar patterning reviewed in $65-67$ (Log2FC $\geq 1$ ) and otx2 that is detected in a subset of GNP (Log2FC $\geq 1.2$ ). At stage 41-42 we observed a significant expansion of both otx2, and zic3 expression territories within the cerebellar plate (Fig. 6Fa,b). zic3 transcripts are present in the URL, and zic3 regulatory regions contain at least three Tcf CRM (Table 1B). otx2 regulatory regions contain either no Tcf CRM (otx2.L), either 3 Tcf CRM (otx2.S). Thereby we argue that zic3 is a direct target of Tcf, whereas otx2 genes may be indirect targets of Barhl1 depletion effect on GNP development.
Amongst the DEG, we also observed an upregulation of faithful reporters of Notch pathway activation hes5 family genes (hes5.1, hes5.2, hes5.3, hes5.4), which regulatory regions contain between 1 and 5 Tcf CRM (Log2FC $\geq 0.5 \leq 0.91$ ) and HES/HEY-Like Transcription Factor (helt) (Log2FC $\geq 2$ ), which regulatory regions lack Tcf CRM. HELT is closely related to Hairy enhancer of split proteins that act as a major downstream effector in the Notch pathway, that is required for the maintenance of NSC, and a proper control of neurogenesis in both embryonic and adult brains ${ }^{68}$.
Finally and importantly amongst the DEG, we identified markers of Wnt pathway activity including one of the bona fide direct target gene of Wnt signalling sp5 (Log2FC $\geq 1.55$; 3 Tcf CRM) (Fig.6B,C; Suppl. Table 1), together with lef1 (Log2FC $\geq 1.55$; one Tcf CRM) known to be a target of $\mathrm{Wnt} / \beta$-catenin signalling ${ }^{69}$, two Wnt secreted signals wnt8b (Log2FC $\geq 1$; one Tcf CRM) (Fig. 6Fc), and wnt2b (Log2FC $\geq 1.3$; one Tcf CRM) (Fig. 6Fd), both of which activate the Wnt canonical pathway, and Wnt Ligand Secretion Mediator (w/s) (Log2FC $\geq 0,5$; one Tcf CRM), which expression in the URL orchestrates cerebellum development in mice ${ }^{70,71}$. Thereby Barhl1 depletion activates Wnt/Tcf activity throughout the cerebellar anlage, specifically within the URL and the cerebellar plate.
Taken together, our transcriptomic analysis identified direct and indirect Barhl1 target genes. Within the R1 territory, when upregulated these genes are involved in i) the maintenance of neural stem/progenitor properties, ii) the enhancement of Notch activity, iii) promoting Wnt/Tcf activity. When down regulated they are mostly involved in inhibiting proliferation and promoting neural differentiation. Our analysis of Barhl1 target genes regulatory regions confirms our functional analysis demonstrating that Barhl1 mostly acts by inhibiting Tcf transcriptional activity.

## DISCUSSION

This study conducted in amphibians provides evidence that the development of the Xenopus Atoh1 lineage is similar to that of higher vertebrates. We show that Tcf transcriptional activity is necessary for inducing the cerebellar URL, as well as atoh1 expression. Furthermore, we demonstrate that Barhl1 plays a critical role in promoting the exit of URL cells from their niche, and initiating their differentiation trajectory towards mature GN. Most importantly, Barhl1 acts primarily by inhibiting Tcf transcriptional activity. Transcriptomic analysis of Barhl1 depletion in the cerebellar anlage confirms our functional study.

## Xenopus represents a novel model for studying cerebellar development

Our ISH experiments provide a developmental map of GNP development in Xenopus, revealing that the processes leading to the emergence of URL derivatives and maturation of GN are similar to those seen in higher vertebrate ${ }^{37,38}$ reviewed in 39,40 . Amongst the important similarities i) the Xenopus URL expresses atoh1, is proliferative and is Tcf responsive; ii) pax6 and barhl1 are early markers of GNP commitment; iii) GNP migrate out of the URL along the cerebellar surface where they appear as the equivalent of the amniote-like EGL; iv) As in amniotes, postmitotic GN express neurod1, and migrate inwardly to form the IGL. Amongst the differences we observed i) a GNP caudal-to-rostral temporal differentiation gradient, with caudal URL differentiating first; ii) Although the EGL express stem/progenitor markers such as atoh1, the Notch pathway activity marker hes4, and $n$-myc, our proliferation analysis confirmed the absence of proliferating cells within the EGL from earlier stages ${ }^{41}$; iii) Although Barh/2 is expressed in the amniote EGL ${ }^{72}$, we could not detect this transcription factor in the Xenopus cerebellar anlage. Our observations suggest that the tetrapod vertebrate Xenopus, the only described anamniote displaying an EGL, could be an alternative useful model for some clinical evaluation of cerebellar developmental defects, especially those related to early cerebellar development ${ }^{41}$ reviewed in 39,40 .

## Tcf transcriptional activity is strictly necessary for atoh1 expression and URL induction

Our data show that within R1, TCF transcriptional activity is strictly necessary for induction of atoh1 expression and of the URL territory. Moreover, TCF inhibition is associated with an increase and/or an acceleration of GNP commitment/differentiation. Interestingly, studies performed in mouse neuroblastoma, and neural progenitor cells in culture, identified two TCF/LEF binding sites present in the 3' enhancer region of Atoh1 that are required for Atoh1 activation ${ }^{73}$. In these cells, the concomitant inhibition of Notch signaling and activation of WNT/Tcf, appear to be required for atoh1 expression ${ }^{73}$. In mice low levels of Notch activity are necessary to induce a glutamatergic cell fate in Sox2-expressing cerebellar progenitors ${ }^{74}$. Whereas it remains to be demonstrated in amniotes, our data argue that concomitant TCF activation and Notch inhibition are responsible for atoh1 expression in the cerebellar primordium
We did not investigate which Tcf/Lef isoforms are transcriptionally active in the amphibian URL. However, our transcriptomic data reveal that lef1 is one of the most up-regulated DEG in the absence of barhl1, suggesting that it is present in the URL and could mediates Wnt signaling in this germinative niche. Three of the the four Tcf isoforms (Tcf712, Tcf7 and Lef1), mostly act as transcriptional activators, whereas the fourth (Tcf7l1) mostly acts as a transcriptional
repressor reviewed in 2 . Transcriptomic analyses of human cerebellar development reveal that the transcriptional activator TCF7 is active in the human URL ${ }^{32}$, whereas Tcf7l2 is detected in the mouse URL ${ }^{33}$. In both species, Tcf7l1 is associated with differentiated GNs ${ }^{25,32}$.
It is well documented that inhibition of TCF7I1-mediated repression is at the core of mouse embryonic stem cell (ESC) self-renewal and pluripotency. In contrast, enhancement of TCF7I1 repressive activity blocks mESC self-renewal, and allows mESC to differentiate, even in the presence of Wnt signaling ${ }^{75-82}$ reviewed in $3,12,83$. In adult mice, canonical WNTs are produced by both NSCs and astrocytes, and WNT/ß-catenin signalling stimulates both NSC self-renewal and neural progenitor cell proliferation ${ }^{4-7,9}$ reviewed in 8 . At least up to stage 50 , we observed that the entire amphibian URL is Tcf active whereas the VZ is not. Early observation using electronic microscopy reported that during the premetamorphic phase, the cerebellum remains in an immature state and that a well-defined EGL up to 8 cells layers is likely to be established by the end of the prometamorphic phase ${ }^{38}$. Taken together these observations indicate that the cerebellar URL displays features of an adult NSC niche. Our data provide new in vivo evidence that Tcf activity is strictly necessary for NSC niche maintenance and function.

## In the URL, barhl1 promotes GNP exit from their germinative niche, towards commitment and differentiation

R1 territory is correctly established in embryos either lacking or overexpressing barhl1, arguing that Barhl1 is not involved in the establishment of the cerebellar anlage. Yet both our functional and transcriptomic data show that Barhl1 activity is strictly necessary for development of URLderived GNPs. Whereas Barhl1 overexpression decreases the size of the URL, and promotes GNP commitment/differentiation, MO-mediated depletion of Barhl1 induces an enlargement of the URL associated with a marked delay in the GNP differentiation process.
Our transcriptomic analysis is consistent with our phenotypic observations. Barhl1-depleted DEG identification reveals that most significant upregulated genes regulate URL cell behavior either by acting on the fine equilibrium between a proliferative state and commitment and / or in maintenance of their stem/progenitor features. Indeed, dmrta2 (dmrt5) expression is specific to neural stem/progenitor cells and has been shown to maintain NSC self-renewing ability ${ }^{84}$. In neural progenitor cells derived from mESC, Dmrta2 maintains proliferation by binding to a target of Notch signaling, Hes1, and upregulates its expression, which will further inhibit neuronal differentiation through repressing the transcription of proneural genes ${ }^{84}$. In the rodent developing and adult brain, the primary function of the orphan nuclear receptor Nr2e1 (also known as $T(x)$ is to maintain NSC pools in an undifferentiated, self-renewing state preventing their premature differentiation ${ }^{85-88}$ reviewed in 89,90 . In mice, otx2 is expressed in GNPs during their massive expansion in the EGL ${ }^{91}$, and its expression is associated with the high proliferation rate of GNP ${ }^{92}$. However, the exact role of otx2 in GNP development has not yet been elucidated. Finally, another upregulated URL target gene is zic3. Although zic3 activity in the URL has not been described in mice, zic3 is involved in maintaining pluripotency in both ESC ${ }^{93,94}$, and neural progenitor cells ${ }^{95}$.
On the other hand, most downregulated DEG are involved in terminal neuronal differentiation, including dendrite development, and axonogenesis. One example is Bhlhe2, which in mice is expressed in the inner EGL, and is a downstream target of Neurod1 in migrating and in differentiated GNs ${ }^{61}$. In vitro KD experiments in primary GN culture indicate that bhlhe 22 is a regulator of post-mitotic GN radial migration towards the IGL ${ }^{96}$.

## In the cerebellar primordium Barhl1 acts through repression of Tcf transcriptional activity

Similar to what we previously described for Barhl2 ${ }^{52}$, in mammalian cells Barhl1 physically interacts with both Gro/Tle and Tcf711. In R1, Barhl1 overexpression phenocopies inhibition of Tcf transcriptional activity, and decreases Tcf activity. Conversely, Barhl1 depletion dramatically increases Tcf transcriptional activity in the URL. Both the increase in URL length, and the delay in GNP commitment/differentiation induced by Barhl1 depletion, are compensated by co-expression of a constitutive inhibitory form of Tcf7l1. Finally, Barhl1-KD embryos display a massive increase of Wnt activity throughout the cerebellar anlage.
Over 75\% of Barhl1 depleted DEG regulatory regions contain at least one Tcf CRM; these include markers of the URL and EGL including zic3, hes5 family genes, and wls. In line with our data in the rodent telencephalon, Dmrta2 is transcriptionally activated by a stabilized form of beta-catenin and inhibited by a dominant-negative form of TCF ${ }^{86}$. Tcf7l1 directly represses transcription of Lef1, which is stimulated by Wnt/ß-catenin activity ${ }^{69}$. These data argue that Barhl1 drives GNP out of the URL via Tcf-mediated repression and that Barhl1 LOF and GOF phenotypes are, at least partly, the result of alteration of its inhibitory effect on Tcf transcriptional activity.

## Barhl1 activates Notch activity in the cerebellar primordium

Hes4, a marker of Notch activity and stemness in Xenopus ${ }^{53}$, is detected at stage 48 in the VZ, the URL, and the EGL. Our RNA-seq analysis reveals that depletion of Barhl1 leads to a significant upregulation of Notch pathway activity. Among upregulated components of Notch signaling, we identified the bHLH TF helt (also known as Heslike and Megane). In mice Helt is expressed in undifferentiated neural progenitors where it acts as transcriptional repressor of proneural genes ${ }^{97,98}$. Similarly, Barhl1 depletion in R1 leads to upregulation of hes5 genes, which are known to inhibit neuronal differentiation by directly repressing proneural genes. In rodents, levels of Notch activity regulate the early progenitor choice between inhibitory (Notch + ) and excitatory GN (Notch -) fate in the VZ ${ }^{74}$. In agreement with its described function in maintaining cells in a primitive state, Notch has been suggested to prevent early GNP differentiation ${ }^{99}$ reviewed in ${ }^{100,101}$, yet its exact function in developing GNP is still debated. Overexpression of a dominant negative form of Barhl2, which binds to Gro/Tle and counters its inhibitory activities, increases the URL/EGL size at the expense of GNP commitment/differentiation. Gro/Tle acts as a corepressor of both TCF and Enhancer of split E(spl), a major transcriptional repressor of Notch target gene activation, including proneural genes ${ }^{102}$ reviewed in 3 . Our findings suggest that there may be as yet unknown crosstalk between Wnt/Tcf and Notch signaling pathways in the maintenance of the cerebellar URL/EGL reviewed in 103

## Barhl genes in amphibian versus mammalian cerebellar development

In mice, Barh/1 and Barh/2 transcripts are detected in the outer URL and the posterior EGL from E11.5 onwards ${ }^{32,45,48,50,72,104,105}$. scRNA-sequencing analysis of mouse cerebellar cells reveals that Barhl1 is associated with early GNP differentiation, whereas Barh/2 expression is uniquely associated with early fate commitment in the Atoh1 lineage ${ }^{33}$. Barhl1 and Barhl2 are highly conserved through evolution reviewed in 3 , and their functional conservation is evidenced
through studies in various species, including mouse, C. elegans and the acorn worm Saccoglossus kowalevskii ${ }^{106,107}$. Our data demonstrate that in the amphibian URL, Barhl1 mostly acts through inhibiting TCF activity. It remains to be investigated which of the Barhl TF inhibits TCF activity in mammals.

## Biological significance of our findings

Our study reveals previously undescribed roles for TCF and Barhl1 in the early development of URL-derived GNPs. We show that Barhl1 is the main repressor of Wnt/TCF activity in this germinative area. Our analysis reveals a set of Barhl1 target genes and opens the way for further characterization of relevant targets in order to create a global picture of GNP development and for further investigations of their relevance in adult NSC niche biology.

## ACKNOWLEDGEMENTS

The authors gratefully acknowledge M. Perron, D. Turner, P. Kreig, J. Christian, R. Vignali and G. Schlosser for gifts of materials and S. Authier and M. Abdelkrim for animal care. We thank the IBPS Aquatic platform supported by Sorbonne Université, CNRS, IBISA and the Conseil Régional Ile-de-France, specifically S. Authier and M. Abdelkrim, for Xenopus care. We thank C. Antoniewski (ArtBio platform, FR3631 IBPS) for tutoring in RNAseq data analysis and the team of G. Almouzni (Institut Curie) for providing high sensitivity RNA screentape system. We acknowledge Ann Lohof and Rachel Sherrard for editing work on the manuscript. This work was supported by the Centre National de la Recherche Scientifique (CNRS - UMR7622), donors to B Durand project, Sorbonne-Université, the Ligue Nationale contre le Cancer Comité lle de France (RS19/75-52 and RS23/75-68). The CNRS supports Beatrice Durand and Mohamed Doulazmi. Alexis Eschstruth is supported by Sorbonne Université, and Johnny BouRouphael by a fellowship from the "Ministère de la Recherche".

## STAR METHODS

EXPERIMENTAL MODEL

Xenopus embryos care and husbandry
$X$. laevis embryos were obtained by conventional methods of hormone-induced egg laying and in vitro fertilization and were staged according to ${ }^{108}$. X. tropicalis transgenic Wnt reporter pbin7LefdGFP has been generated as previously described ${ }^{22,56,57}$. Briefly, the synthetic Wntresponsive promoter consists of 7 copies of TCF/LEF1 binding sites and a TATA box driving destabilized green fluorescent protein (eGFP) and a polyA sequence. gfp expression reveals Wnt/TCF activity. X. tropicalis embryos were obtained by in vitro fertilization. Experimental procedures were specifically approved by the ethics committee of the Institut de Biologie Paris Seine (IBPS) (Authorization 2020-22727 given by CEEA \#005) and have been carried out in strict accordance with the European community directive guidelines (2010/63/UE). B.D. carries the authorization for vertebrates' experimental use $\mathrm{N}^{\circ} 75-1548$.

## METHOD DETAILS

## Plasmids design and preparation

mbarhl1-HA-GR contains the full-length mbarhl1 sequence (two Engrailed-Homology (EH1) motifs, Nuclear Localization Signal (NLS); Homeodomain HD); and the C-terminal part), followed by an HA tag at the C-terminal part. This construct is inducible as it contains a glucocorticoid receptor which can be activated by dexamethasone (10uM). Dexamethasoneinducible mbarh/2-EHs-GR contains the first 182 amino acids (a.a) of mouse Barhl2 full-length cDNA, which correspond to the N-terminal EHs Gro-binding domains, and has been shown to act as a dominant negative ${ }^{52}$. The full-length mbarhl1-HA-GR and truncated mbarhl2-EHs-GR constructs were generated in pCS2+ by Vector Builder. Non-inducible mbarhl1-Myc and xbarhl1-Flag were generated by GeneScript. Peptide sequences of the tags used are the following: HA (YPYDVPDYA); FLAG (DYKDDDDK) and MYC (EQKLISEEDL). The constitutive repressor pCS2-Tcf7l1- $\Delta \beta$ cat-GR was a gift from H. Clevers ${ }^{55}$, and consists of the full-length Tcf7l1 lacking the $\beta$-catenin-binding domain (BCBD), which reinforces its repressive activity. Constructs used for immunoprecipitation assay are pCS2+ mbarhl1-3xFlag-HA which was generated by Vector Builder. It contains the full-length mbarhl1 sequence followed by three Flag tags and one HA tag at the C-terminal part. pCS2+ Myc-Tcf711, pCS2+ Flag-Gro4 and $p C S 2+G r o H A$ have been previously described ${ }^{52}$. All necessary sequences were obtained from NCBI database. Constructs were validated by western blot on extracts from injected embryos or cell lysates.

## mRNA synthesis, morpholino oligonucleotides (MOs) and Xenopus injection

Capped messenger RNAs (mRNAs) were synthesized using the mMessage mMachine kit (Invitrogen) and resuspended in RNAse-free $\mathrm{H}_{2} \mathrm{O}$. Antisense morpholino oligonucleotides (MOs) were generated by Gene Tools. ATG start-site MObarhl1-1 and MObarhl1-2 were designed to block initiation of xBarhl1 protein translation. The MO were designed in a region overlapping the translation initiation site, so that they do not recognize mouse Barhl1 or xbarhl2 mRNA (Fig. S3). To establish the specificity of the MO effect, we tested the ability of MObarhl11 and MObarhl1-2 to specifically inhibit translation of xbarhl1 mRNA. Flag-tagged xbarhl1 (xbarhl1-flag) or myc-tagged mBarhl1 (mBarhl1-myc) were co-injected with MObarhl1-1, or MObarhl1-2, or a control MO (MOct) (Fig. S2). Western blot analysis on extracts from injected embryos confirmed a MObarhl1-mediated dramatic decrease in Xenopus Barhl1 protein levels, while MOct had no effect. We also observed that MObarhl1-1 did not decrease mBarhl1-myc protein levels (Fig. S2; S3). MObarhl1-1 was used for both X. laevis and X. tropicalis as the
mRNA sequence of barhl1 is highly conserved between both species, more specifically in the region on which MObarhl1 is hybridized. Standard control MO from gene tools was used in this study. MO sequences and doses are summarized in table 2.

Xenopus embryos were injected unilaterally in one dorsal blastomere at the four and eight-cell stage together with gfp as a tracer for phenotype analysis by in situ hybridizations (ISH), except for CRISPR/Cas9 genome editing and RNAseq analysis (see corresponding sections in material and methods). MOs were heated for 10 min at $65^{\circ} \mathrm{C}$ before usage. Injected embryos were transferred into 3\% Ficoll in 0.3X Marc's Modified Ringer's (MMR) buffer (stock solution: $1 \mathrm{M} \mathrm{NaCl}, 20 \mathrm{mM} \mathrm{KCl}, 20 \mathrm{mM} \mathrm{CaCl} 2,10 \mathrm{mM} \mathrm{MgCl}, 50 \mathrm{mM}$ HEPES pH 7.4). 10nl of mRNA or MO solution was injected together with a tracer in $X$. laevis while 5 nl were injected in $X$. tropicalis. In X. laevis, MOs or mRNAs were co-injected with gfp mRNA ( 100 pg ). MOs or mRNAs were co-injected with mcherry ( 100 pg ) in $X$. tropicalis. Concentration of injected mRNA and MOs per embryo have been optimized in preliminary experiments. The minimal mRNA or MO quantity that induced the specific phenotype without showing toxicity effects was used. For embryos injected with inducible constructs, half of the injected embryos were treated with $10 \mu \mathrm{M}$ dexamethasone at stage 35 , while the other half were left untreated and served as control. All necessary Xenopus sequences were obtained from https://www.xenbase.org/entry/.

## in situ hybridization

Embryos were staged according to ${ }^{108}$, and collected at the desired stage, then fixed in PFA4\% for $1-2$ hours at room temperature and dehydrated in $100 \% \mathrm{MeOH}$. ISH were performed using digoxigenin (DIG)-labeled probes. Antisense RNA probes were generated for the following transcripts: atoh1, barhl1, hes4, neurod1, pax6, n-myc, otx2, zic3, wnt2b, wnt8b and gfp according to the manufacturer's instructions (RNA Labeling Mix, Roche). pCS2-Gfp is a gift from David Turner (University of Michigan, Ann Arbor, MI, USA). pBSK+xBarhl1 is a gift from Roberto Vignali (Unità di Biologia Cellulare e dello Sviluppo, Pisa Italy). pCS2-Atoh1 is a gift from G. Schlosser (University of Galway, Ireland). pBSK+Wnt2b was a gift from S. Sokol (Icahn School of Medicine at Mount Sinai, NY, USA). pBSK+Wnt8b was a gift from J Christian (University of Utah, USA). ISH was processed following the protocol described by (El Yakoubi et al., 2012; Sena et al., 2019). DISH was processed as described by ${ }^{109}$. For $X$. laevis embryos, following rehydration, the eyes and ectoderm overlying the anterior neural tube were removed, which allows to skip the further Proteinase K (PK) treatment. Dissections weren't performed on $X$. tropicalis embryos which were treated with PK. In both cases, bleaching was carried out, and samples were incubated with the probes overnight. Alkaline phosphatase-conjugated antiDIG or anti-FLUO antibodies (Roche) were incubated 3 hours at room temperature. Enzymatic activity was revealed using NBT/BCIP (blue staining) and INT/BCIP (red staining) substrates (Roche). Following ISH, post-fixation was carried out in PFA 4\% and the neural tubes of control and injected $X$. laevis embryos were dissected in PBS-0.1\% Tween and stored in $90 \%$ glycerol. $X$. tropicalis embryos were stored in PFA 4\%. Dissected neural tubes or embryos were photographed on a Leica M165 FC microscope equipped with Leica DFC320 camera using the same settings to allow direct comparison. Dorsal and lateral views of the dissected neural tubes were photographed.

## Immunofluorescence

Immunofluorescence was carried out as previously described ${ }^{51}$. The entire brains of wild-type (WT) and MO-injected $X$. laevis embryos were carefully dissected and transferred into a tube containing PBS-0.1\% Tween, where they were progressively permeabilized. Samples were incubated with primary antibody (anti-Phospho-Histone H3; Upstate Biotechnology Cat\#06570 ; d1:500) at $4^{\circ} \mathrm{C}$ overnight. Cellular nuclei were stained with bisBenzimide (BB) (Sigma) which was added to the solution containing diluted secondary antibody (Alexa Fluor 488 donkey anti-rabbit IgG; Invitrogen; d1:500) and incubated at $4^{\circ} \mathrm{C}$ overnight. Neural tubes were captured on a Zeiss Axio Observer. $Z 1$ microscope equipped with apotome. Acquisitions were taken using the $Z$ stack tool from the most superficial layer to deeper layers.

## Immunoprecipitation in transfected HEK293T cells

HEK293T cells were cultured in supplemented Dulbecco's modified Eagle's medium (DMEM) (Gibco). Cells were transfected with expression vectors for pCS2-mbarhl1-3xFlag-HA; pCS2-mbarhl1-Myc; pCS2-Tcf7l1-Myc; pCS2-Gro-Flag and pCS2-Gro-HA encoding tagged proteins using the Phosphate Calcium method. Plasmids coding for pCS2+ or pSK+ were used as a supplement to ensure that cells in different dishes were transfected with the same quantity of expression vectors and plasmids (a total of $2 \mu \mathrm{~g}$ ). Thirty-six hours post-transfection, cells were harvested and lysed in ice-cold lysis buffer ( 20 mM Tris pH7.6, $150 \mathrm{mM} \mathrm{NaCl}, 1 \%$ Triton, 1 mM EDTA) supplemented with completeTM protease inhibitor (Roche). Cell lysates were centrifuged 15 min at $14,000 \mathrm{rpm}$. Protein complexes were precipitated from the cell lysates with anti-c-Myc antibody (clone 9E10). Protein complexes were then precipitated with protein A-Sepharose beads (Sigma) pre-washed with lysis buffer. Immunoprecipitated proteins were eluted from protein A beads by heating beads in Laemmli sample loading buffer (BioRad).

## Western blot

Western blot (WB) analysis was performed on protein extracts from injected/WT Xenopus embryos, and on extracts from transfected HEK923T cells. Xenopus embryos were injected with mbarhl1HAGR, xbarhl1Flag, mBarhl1Myc, mBarhl2EHsGR mRNA at the two-cells stage, targeting both blastomeres. Proteins were extracted at stage 10 with lysis buffer ( 10 mM Tris$\mathrm{HCl} \mathrm{pH} 7.5,100 \mathrm{mM} \mathrm{NaCl}, 0.5 \% \mathrm{NP} 40,5 \mathrm{mM}$ EDTA supplemented with a cocktail of protein inhibitors). WB was carried out using the conventional methods. Proteins were separated by $10 \%$ SDS-polyacrylamide gel and transferred to nitrocellulose membrane. Membranes were blocked using $5 \%$ milk and incubated with the corresponding primary and secondary antibodies diluted in 5\% milk (summarized in tables 3 and 4). Proteins were detected with Western Lightning Plus-ECL (Perkin Elmer Life Sciences). Membrane stripping was carried out between two staining steps using stripping buffer (Thermo Scientific) for the removal of primary and secondary antibodies from the membranes. ChemiDoc MP Imaging System (BioRad) was used for imaging the blots.

## CRISPR/Cas9

Three CRISPR target sites (barhl1-1: GAGTCGGACGAGGCCATGGAAGG), barhl1-2: ACCAGCTCTGTGCGACAGAATGG, barhl1-3 : AGAGTTGGACTCCGGGCTGGAGG) cutting respectively at 2,37 and 230 bp from the beginning of the coding sequence were selected for their high predicted specificity and efficiency using CRISPOR online tool (http://crispor.tefor.net/). Alt-R crRNA and tracrRNA were purchased from Integrated DNA

Technologies (IDT, Coralville, IA, USA) and dissolved in duplex buffer (IDT) at $100 \mu \mathrm{M}$ each. cr:tracrRNA duplexes were obtained by mixing equal amount of crRNA and tracrRNA, heating at $95^{\circ} \mathrm{C}$ for five minutes and letting cool down to room temperature. gRNA:Cas9 RNP complex was obtained by incubating $1 \mu \mathrm{~L} 30 \mu \mathrm{M}$ Cas9 protein (kindly provided by TACGENE, Paris, France) with $2 \mu \mathrm{~L}$ cr:tracrRNA duplex in a final volume of $10 \mu \mathrm{~L}$ of 20 mM Hepes-NaOH ph 7.5 , 150 mM KCl for 10 min at $28^{\circ} \mathrm{C}$. $X$. tropicalis one-cell stage embryos were injected with 2 nL of gRNA:Cas9 RNP complex solution and were cultured to the desired stage. For coinjection, the three complexes were mixed at equal quantity.
Single embryo genomic DNA was obtained by digesting for 1 h at $55^{\circ} \mathrm{C}$ in $100 \mu \mathrm{~L}$ lysis buffer ( 100 mM Tris-Hcl pH 7.5, 1 mM EDTA, $250 \mathrm{mM} \mathrm{NaCl}, 0.2 \%$ SDS, $0.1 \mu \mathrm{~g} / \mu \mathrm{L}$ Proteinase K), precipitating with 1 volume of isopropanol and resuspended in 100 $\mu$ L PCR-grade water. The region surrounding the sgRNA binding sites was amplified by PCR using $X$. tropicalis Xt_barhl1_F (CAGCTCCTCCGACTTTTGTG) as forward primer and Xt_barhl1_R (GTTGCCCGTTGCTGGAATAA) as reverse primer. CRISPR efficiency was assessed by T7E1 test ${ }^{110}$ on mono-injected embryos and by detecting deleted fragments on coinjected embryos.

## RNA-sequencing and data analysis

X. laevis embryos were injected with three different conditions: MObarhl1-1; MObarhl1-2 and MOct in the two dorsal blastomeres at four cells stage. At stage 42, neural tubes were extracted in RNAse-free conditions, and the rhombomere 1 which includes the URL was carefully dissected. For each condition, three biological replicates were collected. Each replicate contains three rhombomeres, which was the optimal number to get the minimal RNA concentration required for this experiment (Total RNA concentration was $\sim 30 \mathrm{ng}$ per sample). Briefly, total RNA was extracted using the TRIzol reagent (ambion) according to the manufacturer's instructions. The overall RNA quality was assessed using Agilent High Sensitivity RNA ScreenTape System. Samples with an RNA Integrity Number (RIN) > 9 were used for subsequent analysis.

Sequencing was performed using Illumina NovaSeq (paired-end sequencing) by Next Generation Sequencing Platform (NGS) (Institut Curie). RNAseq data processing was performed using Galaxy server of ARTBio platform (IBPS).

Data sets were aligned against the $X$. laevis v10.1 genome assembly downloaded with its corresponding annotation file from Xenbase ${ }^{111}$. Alignment was made using two read mapping programs, STAR v2.7.8a ${ }^{112}$ and HISAT2 v2.2.1 ${ }^{113}$. Quality control checks were assessed using FastQC v0.73 ${ }^{114}$ and summarized in a single report generated by MultiQC v1.9 ${ }^{115}$. As both alignment programs provided comparable results, we proceeded with STAR alignment tool. The number of aligned reads was counted by featurecounts tool v2.0.1 ${ }^{116}$. Finally, we used the DESeq2 v2.11.40.6 package ${ }^{117}$ to determine differentially expressed genes (DEG) from count tables. In the present study, genes with adjusted $p$ value $\mathrm{pAdj}<0.001$ were selected as significant DEG. Venn diagrams were produced with JVenn v2021.05.12 ${ }^{118}$. Volcano Plots v0.0.5 were generated to show significant upregulated and downregulated genes, only a selection of DEG names were represented.

Further analysis and data visualization were performed using $R$ v4.2.1 package. A heatmap was generated to visualize gene expression across the samples. To overcome the lack of

Xenopus gene ontology (GO) annotation, we replaced $X$. laevis gene symbols with the Human orthologs. Functional enrichment analysis was performed using the compareCluster function of ClusterProfiler v4.8.1 ${ }^{56}$ to identify GO-term enrichment amongst DEG with pAdj<0.001 as threshold. It provides the biological processes, cellular components, and molecular functions of DEG and compares each of the three subgroups between both knockdown conditions.

## QUANTIFICATION AND STATISTICAL ANALYSIS

## Image processing and analysis

For ISH performed on embryos injected unilaterally, comparison of the expression levels between injected and control sides was assessed using a specific macro from ImageJ v2.1.0/1.53c ${ }^{119,120}$. The macro functions based on the RGB color mode. RGB images are split into three channels (red, green, and blue) and pixel values corresponding only to the blue channel are recorded, excluding the red and green channels, since the signal recorded on the blue channel represents the expression levels. For each image, the region of interest (ROI) was specified, and its dimensions were fixed, such that the same ROI is placed on the control and injected side of the embryo which prevents any subjectivity in ROI determination. Measured are the area corresponding to the blue signal; the mean or average value of signal within the selected ROI; and the integrated density which is the equivalent of the product of area and mean, as it sums the values of pixels in the selection. In this study, ratio of integrated density measured in the injected versus control side was assessed. The macro is available from the authors upon request and will be available as a plug-in in ImageJ.

The same macro was used for the analysis of CRISPR/Cas9-injected embryos, except that ROI was placed in all the rhombomere 1 as the entire embryo was targeted. The mean of int. density values of control embryos was compared to each individual int. density value of control and injected embryo. Phenotype penetrance was evaluated by counting and classifying embryos based on the intensity of gfp expression increase.

For immunofluorescence, Z-stack images were reconstructed and processed using ImageJ v2.1.0/1.53c. PHH3-positive cells were counted, and the length of the RL was measured on the control and injected side. Ratio of PHH3-positive cells and RL length in the injected versus control side was measured.

For the same experiment, all images were acquired using the same magnification and camera settings. In this way, all images were processed in a standardized manner, such that results are objectively analyzed. Final images were processed with Adobe Photoshop (v24.00).

## Statistical analysis

Three independent experiments were performed for each condition analyzed. Dissected neural tubes and embryos were analyzed individually, and the results were pooled for data representation. Statistical analyses were implemented with R. Normality in the variable distributions was assessed by the Shapiro-Wilk test. Furthermore, the Levene test was performed to probe homogeneity of variances across groups. Variables that failed the ShapiroWilk or the Levene test were analyzed with non-parametric statistics using the one-way Kruskal-Wallis analysis of variance on ranks followed by Nemenyi test post hoc and Mann-

Whitney rank sum tests for pairwise multiple comparisons. Variables that passed the normality test were analyzed by means of one-way ANOVA followed by Tukey post hoc test for multiple comparisons or by Student's $t$ test for comparing two groups. A p-value of $<0.05$ was used as a cutoff for statistical significance. Results are presented as the means $\pm$ SEM. The statistical tests are described in each figure legend.

## MAIN FIGURES

Figure 1: Temporal and spatial expression pattern of genes involved in granule neuron progenitors' (GNP) development
(A) Neural tube dissection and analysis. Shown on the left is a representation of stage (st.) 45 $X$. laevis embryo. Following ISH, neural tubes are dissected as shown on the middle (entire neural tube) and right (a focus on the rhombomere $1(\mathrm{R} 1)$ ) panels. The proliferation marker nmyc is expressed in the upper rhombic lip (URL) (blue arrow), the ventricular zone VZ (white arrow). Red dotted lines delineate rhombomere 1 (R1) located caudal to the midbrain-hindbrain boundary (MHB). nmyc marks proliferating progenitors at the boundary between R1 and R2 and is used as a marker of cerebellar primordium's caudal limit. (B) ISH analysis of GNP markers in $X$. laevis embryos at the indicated Nieuwkoop and Faber stages. Shown are dorsal and lateral views of the R1. From st. 41 to st. 48 stem/progenitor markers atoh1 (Ba-b'), nmyc (Ca-b'), and hes4 (Ha, a') display a strong expression in the URL and in the EGL. hes4 and nmyc are also detected in the VZ. (Da, a') otx2 expression is first detected in caudal EGL and becomes restricted to the cerebellar plate (CP) (green arrow) at st. 48 (Db, b'). At st. 41 committed GNP markers pax6 (Ea, a') and barhl1 (Fa, a'), together with the differentiation marker neurod1 ( $\mathrm{Ga}, \mathrm{a}$ ') are detected in the caudal EGL and the cerebellar plate. As development proceeds, transcripts for these markers are detected in the CP and their expression significantly increases in this area (E-G, b, b'). Fully differentiated GNs settling in the internal granule layer (IGL) are stained with neurod1 as observed in lateral views of st. 48 $X$. laevis embryos. The CP is devoid of atoh1, hes4, and nmyc expressions. CP: cerebellar plate; VZ: ventricular zone; URL: upper rhombic lip; EGL: external granule layer; R: rhombomere; MHB: midbrain-hindbrain boundary. Scale bar 150 $\mu \mathrm{m}$.

Figure 2: Tcf activity is required for the induction of the URL and its inhibition by Barhl1 is necessary for the proper progression of GNPs development
(A) Overexpression of tcf7/1 inhibits/abolishes atoh1 expression in a dose dependent manner. ISH analysis of atoh1 expression in the rhombomere 1 (R1) showing dorsal views (a, b) and lateral views of control sides ( $a^{\prime}$, b') and injected sides ( $a^{\prime \prime}, b^{\prime \prime}$ ) of stage 45 X. laevis embryos unilaterally injected with 200pg (a, a', a") and 100pg (b, b', b") of inducible tcf7/1- $\Delta \beta$ cat-GR. The non-injected side is an internal control. (B) Forced expression of $t c f 7 / 1$ increased GNP differentiation. ISH analysis of the commitment/differentiation markers barhl1, pax6 and neurod1 (a-c) in stage 45 X. laevis embryos. (C) barhl1 overexpression phenocopies defects of tcf711 overexpression. Dorsal views showing atoh1, barhl1 and neurod1 (a, b, and c respectively) expressions in the R1 primordium of stage $45 X$. laevis embryos injected with $m B a r h l 1 G R(200 \mathrm{pg})$. Lateral views of atoh1 expression in control side (a') and injected side (a") are shown. Integrated densities (IntDen) of markers' expressions were measured. Ratio of markers expression in injected side over control side is represented (Ac; Bd; Cd) and indicated as mean $\pm$ s.e.m. Dotted lines separate injected and control sides. Scale bar $150 \mu \mathrm{~m}$. Square brackets delineate R1. Dex: dexamethasone; inj: injected side. Statistical analysis C: One-way ANOVAone way anova ( $\mathrm{F}_{(2,31)}=437.5 ; \mathrm{p}<0.001$ ) followed by post hoc Tukey test. Bd Cd: student's t-test. Data are presented as means $\pm$ SEM.** $p \leq 0.01 ;{ }^{* * *} p \leq 0.001$; **** $p \leq 0.0001$.

Figure 3: In the cerebellar URL, antagonistic activities of Barhl1 and Tcf are required for the proper development of GNPs
(A-D) Morpholino (MO)-mediated inhibition of Barhl1 induces an ectopic expansion of atoh1 in the upper rhombic lip (URL) and cerebellar plate and delays GNPs differentiation. in situ hybridization (ISH) of stage (st.) 45 X. laevis embryos unilaterally injected with (A) MObarhl11 (15ng) and (B) MObarhl1-2 (20ng). The non-injected side is an internal control. Shown are dorsal views of atoh1 ( Aa ; Ba ), pax6 ( Ab ; Bb ), and neurod1 ( Da ; Db ) expressions in the cerebellar anlage. Lateral views of atoh1 expression in control sides (Aa', Ba') and injected sides (Aa", Ba") are shown. (C) Quantification of (A) and (B). (Da-c) MObarhl1 phenotype is rescued by mBarhl1 overexpression. ISH analysis showing rescue of neurod1 expression in embryos co-injected with MObarhl1-1 and mBarhl1 mRNA. (Dd) Quantification of (D). (E) Inhibition of Tcf activity compensates for Barhl1 depletion. ISH analysis of pax6 expression in the cerebellar anlage of stage 48 X. laevis embryos unilaterally injected with (Ea) MObarhl1-1 (15ng), (Eb) tcf7l1- $\Delta \beta$ cat-GR at 100pg and (Ec) tcf7/1- $\Delta \beta$ cat-GR at 200pg. pax6 expression was rescued when MObarhl1-1 (15ng) was co-injected with tcf7/1- $\Delta \beta$ cat-GR at 100 pg (Ed) and at 200pg (Ee). (f) Quantification of (E). Ratio of markers expression in injected side over control side is indicated as mean $\pm$ s.e.m. Dotted lines separate injected and control sides. Scale bar $150 \mu \mathrm{~m}$. inj: injected side. Statistical analysis was carried out using student's t -test. C:atoh1:One-way ANOVA $\left(\mathrm{F}_{(2,21)}=19.9 ; \mathrm{p}<0.001\right)$ followed by post hoc Tukey test. pax6: Oneway ANOVA $\left(F_{(2,14)}=8.63 ; p=0.004\right)$ followed by post hoc Tukey test. Dd:Kruskal-Wallis test (Chi square=35.6 $p<0.001$, df=3) followed by Nemenyi test post hoc. Ef:One-way ANOVA $\left(\mathrm{F}_{(4,31)}=32.9 ; \mathrm{p}<0.001\right)$ followed by post hoc Tukey test.Data are presented as means $\pm$ SEM $^{*} p \leq 0.05$; ** $p \leq 0.01$; ${ }^{* * *} p \leq 0.001$; **** $p \leq 0.0001$.

Figure 4: Barhl1 physically interacts with Tcf7I1 and Gro and limits Tcf transcriptional activity
(A) HEK293T cells were transfected with plasmids encoding indicated tagged proteins. Cell lysates were immunoprecipitated (IP) by anti-cMyc antibody. Input and IP samples were subjected to western blot analysis using indicated antibodies. Equal amounts of protein lysates were loaded on SDS-gel. (Aa) Barhl1 interacts with Groucho 4 (Gro4) and Tcf711. The interaction between Barhl1 and Tcf7l1 is detected in the presence and in the absence of Gro. (B) Tcf activity is detected in the URL in an area overlapping with that of atoh1, and complementary to that of barhl1. ISH in $X$. tropicalis pbin7LefdGFP line at indicated stages (st.) showing gfp (Tcf activity) (Ba, b, c, d), atoh1 (Ba', b', c', d') and barhl1 (Bc", d") expression patterns. (Bc'") DISH showing expression of barhl1 (blue) and gfp (red). Dorsal views of one side of the embryos are shown. (C, D) Barhl1 limits Tcf transcriptional activity in vivo. ISH analysis of gfp expression in $X$. tropicalis pbin7LefdGFP embryos injected either unilaterally with (Ca) mBarhl1GR (200pg) and (Cb) MObarhl1-1 or before division with (Db) Crispr-barhl1. Embryos injected with Crispr-barhl1 were compared to their wild-type (WT) siblings. (E) Interaction between Barhl1 and Gro is required for Barhl1 function. mBarh/2EHsGR only contains the two EH1 motifs of Barhl2 and acts as a dominant negative by capturing Gro. (Ea) ISH showing atoh1 expression in injected versus control side. Integrated densities (IntDen) of markers' expressions are measured. Ratio of markers expression in injected side over control side is represented (Cc; Dc; Eb) and indicated as mean $\pm$ s.e.m. Percentage of phenotype penetrance is quantified in embryos injected with Crispr/barh/1 versus WT embryos based on indicated criteria. Dotted lines separate injected and control sides. Scale bar $150 \mu \mathrm{~m}$. inj: injected side. Statistical analysis Cc: One-way $\operatorname{ANOVA}\left(\mathrm{F}_{(2,35)}=111,3 ; \mathrm{p}<0.001\right)$ followed by post hoc Tukey test.was carried out using Eb: student's t-test. Data are presented as means $\pm$ SEM * $p \leq 0.05 ;{ }^{* * *} p \leq 0.001 ;{ }^{* * * *} p \leq 0.0001$.

Figure 5: In the URL, Barhl1 activity as an inhibitor of Tcf transcription is required for GNPs to exit their germinative zone and become post-mitotic
(A) Barhl1-KD induces an increase in the URL length associated with increased proliferation within this compartment. (a-d) Imaging of cerebellar anlage of stage 48 X . laevis tadpoles unilaterally injected with MOct and MObarhl1-1 (15 ng). Collected neural tubes were stained for the mitotic marker PhosphoHistone-H3 (PHH3) (green) merged with bisbenzimide (BB) (red). In Xenopus, the EGL is devoid of proliferating cells. (e-g) Quantifications of (A). The ratio of (e) measured URL length and (f) PHH3+ cells in injected side over control side are represented. (Ac, d) PHH3 positive cells are ectopically detected in the cerebellar plate (Ac, d white arrow heads) of injected embryos. (g) Percentage of PHH3+ cells located inside the URL compared to that located outside the URL were quantified on the injected side and on the control side. (E) The abnormal increase in URL length is rescued upon co-inhibiting Tcf and Barhl1 activities. ISH analysis of $n$-myc expression in the cerebellar anlage of stage $48 \times$. laevis embryos unilaterally injected with (Ba) MObarhl1-1 (15ng), (Bb) tcf7l1- $\Delta \beta$ cat-GR at 100 pg and (Bc) tcf7l1- $\Delta \beta$ cat-GR at 200pg. n-myc marks the boundaries between different rhombomeres which allows the exact measurement of URL length. URL length was rescued when MObarhl1-1 (15ng) was co-injected with tcf7/1- $\Delta \beta$ cat-GR at 100 pg (Bd) or at 200pg (Be). Ratio of URL length in injected side over control side is represented (Bf) and indicated as mean $\pm$ s.e.m. Dotted lines separate injected and control sides. Scale bar 150 mm. inj: injected side; cp: choroid plexus; URL: Upper Rhombic Lip; VZ: Ventricular Zone; R1-R2: Rhombomere 1 and 2; MHB: Midbrain-Hindbrain Boundary. Statistical analysis Ae, Af: was carried out using student's t-test. Bf: One-way $\operatorname{ANOVA}\left(F_{(4,49)}=65.1\right.$; $\left.\mathrm{p}<0.001\right)$ followed by post hoc Tukey test.Data are presented as means $\pm$ SEM ${ }^{* *} p \leq 0.01$; ${ }^{* * *} p \leq 0.001$; ${ }^{* * * *} p \leq 0.0001$.

Figure 6: RNA-sequencing data processing and analysis
(A) Principal Component Analysis (PCA) plots were obtained based on RNAseq data aligned with STAR and reads counted using feature-counts. Three samples have been generated for each condition. Sample groups are represented by different colors as indicated. Each dot refers to a sample. Samples showing similar gene expression profiles are clustered together.
(B) Volcano plots showing a selection of significant DEGs with pAdj < 0.001 in (a) MObarhl11 vs MOct and (b) MObarhl1-2 vs MOct. Upregulated genes with Log2FC>0.4, and downregulated genes with Log2FC<-0.4 are shown. Red and blue dots indicate significant DEGs that are upregulated and downregulated, respectively. Grey dots denote RNAs with nonsignificant difference. PCA and volcano plots were generated using Galaxy. (C) Differentially expressed genes (DEGs) visualization Heatmap displaying expression profiles of most significantly upregulated and downregulated DEGs for each condition (MObarhl1-1 vs MOct and MObarhl1-2 vs MOct). Each row represents a gene, and each column represents a sample. Results are shown as a gradient from blue (downregulated) to dark orange (upregulated). Heatmap is generated using R package. (D) Gene ontology enrichment comparison. Shown on Y axis are the altered molecular functions (a) and biological processes (b) for selected (A) upregulated (Log2FC $\geq 0.4$, PAdj $<0.001$ ), and (b) downregulated (Log2FC $\leq-$ 0.4, PAdj<0.001) DEGs respectively. Enrichment analysis comparing functional profiles among MObarhl1-1 and MObarhl1-2 was performed on the DEGs in common between both conditions. Results are visualized as a dot plot based on indicated gene counts and adjusted $p$-values for enrichment. Dot size corresponds to the count of differentially expressed genes associated with the molecular function or the biological pathway, and dot color refers to the adjusted P -value for enrichment. (E) TCF Cis Regulatory Motifs (CRM) in regulatory regions of MOBarhl1 DEGs: pie chart of \% of MObarhl1 DEGs containing either no TCF CRM
(orange), one TCF CRM (grey), two TCF CRM (yellow) and three or more TCF CRM (blue) located 5 Kb upstream or downstream of their TSS. (F) ISH analysis of 4 DEGs: Dorsal views R1 territory of st. 42 X . laevis embryos unilaterally injected with MObarhl1-1 using wnt8b, wnt2b, zic3, otx2 as ISH probes as indicated. inj: injected side.

Table 1: Barhl1 and TCF Cis Regulatory Motif (CRM) on regulatory regions of Barhl1 depleted DEGs. We explore the putative transcription factor-target relationships of Barhl1 (A) and Tcf (B) on Barhl1 depleted DEGs (PAdj<0.001, Log2FC $\geq 0.45$ or Log2FC $\leq-0.45$ ). We applied R packages Biostrings ( v 2.64 ) and GenomicFeatures ( v 1.48 ) and determine potential (A) Barhl1 binding sites ( $5^{\prime}-\mathrm{C}-\mathrm{A}-\mathrm{A}-\mathrm{T}-\mathrm{T}-\mathrm{A}-\mathrm{C} / \mathrm{G}-3^{\prime}$ ) (and the mirror sequence ( $5^{\prime}-\mathrm{G} / \mathrm{C}-\mathrm{T}-\mathrm{A}-\mathrm{A}-\mathrm{T}-\mathrm{T}-$ G-3')) ${ }^{60}$, or (B) TCF binding sites ( $5^{\prime}-\mathrm{C}-\mathrm{T}-\mathrm{T}-\mathrm{T}-\mathrm{G}-\mathrm{A} / \mathrm{T}-\mathrm{A}-3^{\prime}$ ) (and the mirror sequence ( $5^{\prime}$ '-T-A/T-C-A-A-A-G-3')) ${ }^{61,62} 5 \mathrm{~Kb}$ upstream and downstream of the Transcription Start Site (TSS) of DEGs using $X$. laevis v10.1 genome assembly downloaded with its corresponding annotation file from Xenbase. For each gene identified through its EntrezID and its symbol, is indicated the sequence of the detected putative CRM and its position within the gene locus.
