22 SUMMARY

23	Intestinal stem cells (ISCs) drive the rapid regeneration of the gut epithelium to maintain
24	organismal homeostasis. Aging, however, significantly reduces intestinal regenerative capacity.
25	While cellular senescence is a key feature of the aging process, little is known about the in vivo
26	effects of senescent cells on intestinal fitness. Here, we identify the accumulation of senescent
27	cells in the aging gut and, by harnessing senolytic CAR T cells to eliminate them, we uncover
28	their detrimental impact on epithelial integrity and overall intestinal homeostasis in natural aging,
29	injury and colitis. Ablation of intestinal senescent cells with senolytic CAR T cells in vivo or in vitro
30	is sufficient to promote the regenerative potential of aged ISCs. This intervention improves
31	epithelial integrity and mucosal immune function. Overall, these results highlight the ability of
32	senolytic CAR T cells to rejuvenate the intestinal niche and demonstrate the potential of targeted
33	cell therapies to promote tissue regeneration in aging organisms.

46 **INTRODUCTION**

Tissue regeneration is essential for maintaining organismal homeostasis¹. Within the body, the 47 intestinal epithelium is one the highest self-renewing organs². Intestinal stem cells (ISCs), located 48 49 at the crypts of the intestinal epithelium, are key in this process through their ability to self-renew and differentiate into various intestinal cell types². However, aging significantly impacts them 50 leading to diminished regenerative capacity and a decline in intestinal epithelial function³⁻⁷. A 51 52 number of strategies have been tested to enhance the activity of ISCs including dietary 53 modifications and small molecules, but the sustainability, safety and long-term effects of these interventions remain unclear⁷⁻¹². Given the high incidence of gut disorders in the elderly¹³ there is 54 55 a pressing need to develop more targeted and effective strategies to rejuvenate ISC function in 56 aging. Therefore, understanding the cellular basis of this regenerative decline and developing 57 new therapeutic approaches would have broad implications for aging research and healthspan-58 promoting interventions.

59

A key determinant of organismal aging is cellular senescence^{4,14}. Senescence is a stress 60 response program characterized by stable cell cycle arrest and the production of a 61 proinflammatory senescence-associated secretory phenotype (SASP)¹⁵⁻¹⁷. Senescent cells 62 63 accumulate with age and contribute to the pathophysiology of a wide range of age-related diseases^{14,18-21}. How senescent cells impact tissue regeneration remains an area of active 64 research. On one hand, senescent cells have been shown to promote wound healing²², in vivo 65 reprogramming²³ and lung regeneration in response to injury²⁴. Conversely, senescent cells impair 66 skeletal muscle regeneration ²⁵ and hematopoietic stem cell activity²⁶. These different outcomes 67 68 highlight the need to gain a better understanding of the impact of senescent cells on different 69 stem cell niches. In this regard, little is known about the presence and effect of senescent cells in 70 the aging intestine. In addition, exploring how elimination of senescent cells through selective

approaches impacts tissue homeostasis is crucial for generating successful therapeutic
 regenerative strategies.

73

74 We recently developed the first chimeric antigen receptor (CAR) T cells able to specifically eliminate senescent cells efficiently and safely^{27,28}. CARs redirect the effector function of T cells 75 76 towards a specific cell-surface antigen and are highly selective at eliminating target-expressing 77 cells^{29,30}. Specifically, senolytic CAR T cells recognize and lyse cells that express the urokinaseplasminogen activator receptor (uPAR)^{27,28}. uPAR has been shown to be highly expressed on the 78 79 surface of senescent cells in multiple models in mice and humans including in natural aging, 80 where uPAR positive cells contribute to the majority of the senescence burden present in aged tissues^{27,28}. 81

82

Here, we set to study the presence and significance of cellular senescence on intestinal fitness during physiological aging and injury. For this, we harnessed senolytic CAR T cells to ablate senescent cells in the intestine, wherein we uncovered their therapeutic potential to promote regeneration.

87

88 **RESULTS**

Age-dependent accumulation of senescent cells in murine and human small intestines correlates with decreased intestinal fitness

As a first step to investigate the presence of senescent cells accumulated during physiological aging in the small intestine we performed senescence-associated beta-galactosidase staining (SA- β -gal) in the proximal jejunum of young (3 months old) and old (20 months old mice) and found a significant increase in the number of SA- β -gal⁺ cells with aging (Figure 1A). To further characterize them, we performed RNA in situ hybridization (ISH) for additional markers of

senescence such as *Cdkn2a*, encoding the CDK4/6 inhibitor and tumor suppressor p16^{lnk4a} and 96 97 Plaur, the gene for uPAR, and found an age-dependent increase in their co-expression in the 98 small intestine (Figure 1B). Given that the correlation between *Plaur* expression and uPAR surface protein expression is not linear²⁸³¹ we performed flow cytometry on isolated intestinal crypts from 99 100 young (3 months old) and old (20 months old) mice. As expected, we observed a significant 101 increase in the percentage of cells expressing surface uPAR in the aged intestines compared to 102 young counterparts (Figure 1C). uPAR+ cells were mostly of epithelial origin and were positive for 103 SA- β -gal staining (Figure D-E). To better characterize the cell types that upregulate uPAR surface 104 expression in this setting we isolated uPAR+ and uPAR- cells from aged (20 months old) intestines 105 through FACS and performed single cell RNA sequencing (scRNAseq) (Figure S1A). We profiled 9430 uPAR+ and 7379 uPAR- individual cells. Using unsupervised clustering and marker-based 106 107 cell labelling³², we assigned 10 different cell types which were visualized using Uniform Manifold 108 Approximation and Projection (UMAP) (Figure S1B-C). Analysis of the different populations for 109 uPAR expression indicated that stem cells, enterocytes and macrophages were the most 110 prominent uPAR-expressing populations in the aged small intestine (Figure 1F and S1D). 111 Importantly, when senescent cells were identified using transcriptomic signatures of senescence³³ 112 we found that uPAR positive cells constituted a significant fraction of the senescent-cell burden 113 present in aged intestines (Figure 1G and S1E).

114

To explore whether a similar accumulation of senescent cells took place in humans we surveyed scRNAseq data from ileal samples of old (65-70 years old) and young (25-30 years old) individuals³⁴ (Figure S1F-J). Similar to our results in mice, we observed that aging led to the accumulation of cells expressing transcriptomic signatures of senescence³³ in the human small intestine (Figure 1H and S1J). Additionally, while we were limited to the analysis of *PLAUR* transcript expression, we found that its levels significantly increased with age paralleling the increase in senescence signatures in this setting (Figure 1I). Indeed, when we performed RNA 122 ISH for *CDKN2A* and *PLAUR* in human middle aged (56 years old) and old (89 years old) 123 individuals we found an age-related increase in cells co-expressing them (Figure 1J). Taken 124 together, these results indicate that uPAR positive senescent cells accumulate in the small 125 intestines of both mice and humans during physiological aging.

126

127 To start elucidating the potential effect of this accumulation of senescent cells in the intestine we 128 employed a mouse model that allows senescent cell imaging through the expression of a luciferase reporter regulated by the p16^{lnk4a} promoter³⁵. Using these p16^{Luc} mice we observed that 129 130 their senescent cell burden correlated with a decrease in overall intestinal function (Figure 1K-M). 131 Thus, higher levels of bioluminescence correlated with increased intestinal permeability in these 132 animals, decreased organoid forming ability of their crypts and significant changes in their 133 microbiome composition (Figure 1K-M). Collectively, these data point towards a correlation 134 between senescent cell accumulation and decreased intestinal fitness including ISC activity and 135 barrier function.

136

137 Senolytic uPAR CAR T cells improve age-induced defects in intestinal epithelial integrity

To functionally interrogate in vivo the physiological consequences of this age-dependent 138 139 accumulation of uPAR-positive senescent cells in the intestine, we harnessed CAR T cells to 140 eliminate them. For this, we employed second generation murine uPAR targeting CAR T cells 141 (m.uPAR-m.28z) that express a single-chain variable fragment (scFv) recognizing mouse uPAR and have mouse CD28 as costimulatory domain^{27,36}. uPAR CAR T cells are safe and highly 142 143 effective at eliminating senescent cells in vivo including in the context of aging where a single 144 infusion has been shown to lead to long-term persistence of the senolytic CAR T cells and their effects^{27,28}. 145

146

147 Thus, we performed studies in syngeneic mouse strains in which uPAR CAR T cells or control 148 untransduced T cells (herein designated UT) from CD45.1 mice were intravenously infused into 149 CD57BL/6 CD45.2 young (3 months old) and old (18-20 months old) mice (Figure S2A). We 150 employed a dose of 0.5x10⁶ CAR-positive cells, which we have observed to be optimal for senolytic efficacy and safety balance^{27,28}. In particular, at this dose there is enough elimination of 151 152 senescent uPAR positive cells to result in phenotypic improvements in multiple models of fibrosis 153 and aging without developing signs of toxicity either in the form of cytokine release syndrome or 154 histological toxicities^{27,28}. Importantly, in this setting and at this dose, uPAR CAR T cells were 155 detected in the intestinal epithelium of the mice 6 weeks after infusion, where they were present 156 in significantly higher numbers in aged animals correlating with the increased expression of 157 surface uPAR in the small intestine with age (Figure 2A and 1C). uPAR CAR T cells predominantly 158 exhibited a cytotoxic effector T cell phenotype (CD8+ and CD44+) (Figure S2B and S2C) with low 159 levels of exhaustion markers, and were activated at this time point (Figure S2D and S2E) 160 suggesting that they were recognizing uPAR positive cells in this tissue. Administration of uPAR 161 CAR T cells indeed led to a significant decrease in the number of uPAR-positive cells as well as 162 a significant reduction in the number of SA-β-Gal positive cells in the small intestines of aged 163 uPAR CAR T-treated mice versus those that received control UT cells (Figure 2B, 2C, 2D).

164

Phenotypically, elimination of senescent cells led to improvements in age-related defects in intestinal epithelial integrity. Thus, treatment with uPAR CAR T cells in aged mice significantly rescued age-induced increased intestinal permeability or "leaky gut"³⁷ as measured by decreased plasma levels of FITC-Dextran 4h after oral administration in aged uPAR CAR T treated mice as compared to aged UT-treated animals (Figure 2E). In addition, administration of uPAR CAR T cells led to an increase in the number of proliferating (EdU positive) epithelial cells in the intestinal crypts (Figure S2F and S2G).

172

173 To further explore the impact of uPAR CAR T cells on intestinal regeneration after injury we challenged the mice with 15Gy abdominal irradiation which elicits cytotoxicity, crypt loss and 174 senescence in the intestinal epithelium⁹. Irradiation of young and old UT and uPAR CAR T treated 175 176 animals induced selective damage to the intestinal epithelium that was followed by a regenerative phase after injury (Figure S2H, 2F-J). As described³⁸⁻⁴⁰, aged UT treated mice tolerated irradiation 177 178 worse than their younger counterparts exhibiting increased weight loss over time, greater increase 179 in intestinal permeability, lower numbers of proliferating (EdU positive) cells, and higher numbers 180 of apoptotic caspase 3-positive cells (Figure 2F, 2G,2H,2I,2J). Treatment with uPAR CAR T cells 181 significantly reversed these effects, especially in aged mice where the burden of senescent cells 182 was higher, significantly mitigating the age-related decline in regenerative potential following injury 183 (Figure 2F,2G,2H,2I,2J).

184

Furthermore, we explored the effects of senolytic CAR T cells in an intestinal injury model of experimental colitis induced by dextran sulfate sodium (DSS) (Figure S2I). In this setting, treatment with uPAR CAR T cells significantly reduced body weight loss, colonic edema and histological severity of the disease compared to controls (Figure 2K,2L,2M).

189

Taken together, these results show that the accumulation of uPAR positive senescent cells in aged and injured intestines contributes to decreased epithelial integrity and reduced regenerative capacity. Thus, elimination of senescent cells with uPAR-targeting CAR T cells significantly rescues these defects.

194

195 uPAR CAR T cells rejuvenate aged intestinal stem cells

To elucidate the basis for the enhanced regenerative effects associated with uPAR CAR T treatment in aged mice, we performed single cell RNA sequencing in young (3 months-old) and old (20 months-old) mice 6 weeks after treatment with 0.5x10⁶ of uPAR CAR-positive or

untransduced T cells (Figure 3A-H and S3A-H). We profiled 37,829 single cells and identified 12
different cell types, which were visualized using UMAP (Figure S3A-B).

201

202 In accordance with previous histological studies, the proportions of the different cell types varied with aging^{38,41}. Specifically, aged intestinal crypts presented a reduced abundance of intestinal 203 204 stem cells (ISCs) (Figure 3A-B). Importantly, these aged ISCs manifested a significant decrease 205 in the expression levels of well-established stemness genes such as Lgr4, Myc, Sox9, Olfm4, 206 Malat1 and Ccnd1 suggesting impaired stem cell activity with age (Figure 3C-D)^{5,38,41}. 207 Interestingly, the intervention with uPAR CAR T cells in aged mice overturned this age-related 208 decline in ISCs abundance and stemness gene expression program (Figure 3E-H). Specifically, 209 besides being present at higher proportions, ISCs from aged uPAR CAR T treated mice were 210 significantly enriched in stem cell signature genes compared to aged UT control mice (Figure 3G-211 H).

212

213 To assay the regenerative potential of these ISCs we performed clonogenic organoid formation 214 assays from epithelial crypts as well as from sorted Epcam-positive (Epcam⁺) cells from the small 215 intestines of young and old, uPAR CAR T or UT-control treated mice 6 weeks after infusion (Figure 3I-K). Congruent with previous reports ^{5,7,11}, crypts from old mice generated significantly fewer 216 217 organoids than those from young mice (Figure 3I-K). However, in vivo treatment with uPAR CAR 218 T cells rescued the ability of aged crypts or sorted Epcam⁺ cells to efficiently generate organoids 219 (Figure 3I-K). These results highlight the ability of senolytic CAR T cells to enhance ISC activity 220 and regeneration in aged mice.

221

To further understand whether the improved regenerative capacity in response to uPAR CAR T
 cells is due to their direct effects on the ISCs, we compared the stemness gene signature of aged
 uPAR⁺ and uPAR⁻ ISCs. Interestingly, ISCs expressing surface uPAR protein had significantly

225 lower expression of key stem genes such as Lgr4, Lgr5, Sox9, Olfm4 and Ccnd1 than uPAR 226 negative counterparts (Figure 3L,M). Similarly, analysis of PLAUR gene expression in aged 227 human ISCs showed that PLAUR+ ISC have reduced expression levels of genes involved in stem 228 cell activity compared to PLAUR- ones (Figure 3N,O). To assess whether in vitro elimination of 229 uPAR⁺ cells in intestinal crypts would be sufficient to rejuvenate them, we co-cultured crypts from 230 young (3 months old) and old (20 months old) mice with either untransduced T cells or uPAR CAR 231 T cells (Figure 3P-S). As expected, uPAR CAR T cells preferentially targeted old crypts that harbor 232 more senescent cells (Figure 3P-Q and S3I). Notably, dissociated single cells from uPAR CAR T 233 treated old organoids gave rise to more organoids in secondary subcultures compared to UT old 234 treated controls (Figure 3R-S). Overall, these results suggests that surface uPAR expression 235 identifies dysfunctional ISCs and their elimination with senolytic CAR T cells is enough to 236 rejuvenate the regeneration potential of aged intestinal crypts.

237

In addition to ISCs, aging results in deficits in the functions of mature epithelial cell types such as
 Paneth, goblet, enteroendocrine cells and enterocytes^{5,42,43}. Compared to UT counterparts, *in vivo* treatment with uPAR CAR T cells in old mice elicited gene expression changes in these mature
 epithelial cell types that correlate with increased functional fitness (Figure S3J-K).

242

Collectively, these data support the notion that removal of uPAR positive cells through senolyticCAR T cells enhances overall intestinal function in aging.

245

Senescent cells drive age-induced intestinal epithelial MHC-II upregulation and mucosal
 immune dysfunction

Age-induced defects in intestinal fitness (such as increased permeability and dysbiosis) have been linked to a cumulative and chronic inflammatory state referred to as "inflammaging"⁴³⁻⁴⁶ which in turn further exacerbates intestinal functional decline^{37,47}. Indeed, we observed a

significant upregulation of the inflammatory response in the small intestine with aging (Figure 4AB and S4A). Interestingly, we observed that treatment with uPAR CAR T cells in aged animals
significantly abrogated the expression of inflammatory response genes suggesting that senescent
cells play a key role in the age-related inflammatory state in the intestine (Figure 4C-D and S4B).

256 Senescent cells are highly pro-inflammatory in nature and not only secrete cytokines and 257 chemokines as part of their SASP but also upregulate immune interacting surface molecules such 258 as MHC-I^{16,48,49}. In younger organisms, this leads to their clearance by the immune system 259 restoring tissue homeostasis; however, during aging, altered immune function leads to chronic 260 inflammaging⁵⁰. Nonetheless, the exact mechanisms of the interactions between senescent and immune cells are highly tissue and context specific and remain elusive⁵¹. To get a better 261 262 understanding of the mechanism whereby senescent cells were promoting intestinal inflammation 263 in aging we studied the expression profile of the most differentially expressed genes related to 264 inflammation in aged intestines upon treatment with uPAR CAR T cells (Figure 4D). Among these, 265 genes encoding MHC-II molecules (such as H2-Ab1, H2-Aa and Cd74, which are upregulated in 266 aging (Figure 4B and S4D)) were among the most significantly downregulated in intestinal 267 epithelial cells (including ISC) upon elimination of senescent cells (Figure 4D and S4E). We and 268 others have recently shown that MHC-II expression on ISCs mediates immune-stem cell crosstalk 269 in the intestinal epithelium influencing inflammation, response to infection and anti-tumor 270 immunity⁵²⁻⁵⁵. Interestingly, we found that MHC-II expression was significantly increased on 271 intestinal uPAR-positive senescent epithelial cells in both mice and humans (Figure 4E-F). 272 Expression of MHC-II on senescent cells has been observed to date in two artificial models of oncogene-induced senescence triggered by the overexpression of mutant Nras^{56,57}; however, 273 274 whether senescent cells express functional MHC-II in vivo in physiological models such as aging 275 is unknown. To explore whether naturally occurring senescent cells in the intestine could uptake 276 antigens, we orally administered ovalbumin conjugated to Texas red dye to aged animals and

277 examined the percentage of Texas red-positive cells in the intestines of these mice 1 hour after administration. Interestingly, we found that senescent epithelial cells (identified as CD45⁻, Epcam⁺, 278 279 uPAR⁺) were more likely to take up antigen than non-senescent epithelial cells (CD45⁻, Epcam⁺, 280 uPAR⁻) (Figure 4G). To further study whether senescent cells could not only uptake antigen but 281 also present it on MHC-II molecules and drive CD4 T cell responses, we sorted CD45 negative, 282 Epcam positive uPAR positive or negative cells and co-cultured them with ovalbumin 323-339 283 peptide and OT-II cells (which are specific for OVA 323-339 presented by MHC-II molecules). We 284 observed that senescent cells were indeed able to stimulate OT-II T cell proliferation (Figure 4H). 285 These results suggest that senescent epithelial cells that accumulate in the small intestine during 286 natural aging express elevated levels of MHC-II and are able to uptake and present antigens to 287 CD4 T cells to stimulate their proliferation. Consistent with this observation, uPAR CAR T cell 288 treatment led to decreased expression of markers of immune senescence on endogenous T cells 289 present in the aged intestinal crypts such as senescent CD4 CD153 and PD1 positive cells (Figure 4I) and senescent CD28 negative KLRG1 positive T cells (Figure 4J)^{58,59}. In addition, aged 290 291 animals treated with uPAR CAR T cells presented decreased levels of nonspecific IgA, a marker 292 of gut mucosal aging ^{60,61} (Figure 4K); were able to mount better specific immune responses to 293 mucosal vaccines (Figure 4L) and presented a microbiome composition more similar to that of 294 younger animals (Figure 4M).

295

296 Overall, these results support a crucial role for senescent cells in driving chronic intestinal 297 inflammation and mucosal immune dysfunction in aging and identifies epithelial MHCII expression 298 in the aged intestine as a hallmark of mucosal inflammaging.

299

300 **DISCUSSION**

Herein we identify for the first time the accumulation of intestinal senescent cells during 301 302 physiological aging and validate uPAR as a reliable marker of senescence in this setting. 303 Harnessing uPAR-targeting CAR T cells we show that *in vivo* elimination of senescent cells in 304 aged animals significantly improves epithelial integrity and overall intestinal homeostasis. These 305 results suggest that in the context of the aging intestinal stem cell niche and epithelium, senescent 306 cells significantly impair regenerative capacity. Indeed, we identify uPAR expression as a marker 307 of dysfunctional ISCs whose in vitro elimination is sufficient to rejuvenate the regenerative 308 potential of aged intestinal crypts.

309

310 Beyond defects in regeneration, the aged intestinal niche is characterized by chronic inflammation 311 and defects in mucosal immunity. Interestingly, in our work we uncover a key role of senescent 312 cells in driving mucosal immune dysfunction and identify epithelial MHC-II expression as a proxy 313 of inflammaging in the gut. Accordingly, elimination of senescent cells by uPAR CAR T cells leads 314 to downregulation of epithelial MHC-II expression and improved overall mucosal immune function. 315 Previous single cell analysis of intestinal epithelial cells identified ISCs subtypes with reduced levels of MHC-II that correlated with enhanced stem cell activity⁵³. Whether elevated MHC-II levels 316 317 in aged ISCs contributes to their functional deficits warrants further investigation.

318

319 Overall our results have significant therapeutic implications. They represent the first proof-of-320 concept that senolytic CAR T cells can effectively promote regeneration in the context of intestinal 321 aging, enteritis and colitis. While further work will be needed to ascertain the effect of senolytic 322 CAR T cells in other stem cell niches; their ability to rejuvenate old ISCs and their 323 microenvironment highlights-the promise of immune cell engineering as a new therapeutic 324 modality in regenerative medicine. These findings fit squarely within the emerging landscape of 325 cellular therapy beyond non-cancer conditions where CAR T cells have been shown to have a 326 high therapeutic profile in infectious and autoimmune diseases as well as in fibrosis and

senescence-driven pathologies⁶². Future CAR T approaches could be directed against different surface proteins upregulated in dysfunctional stem cell niches; might employ combinatorial strategies ^{63,64} or utilize other immune cell types or delivery routes ⁶⁵. In addition, the ability of CAR T cells to incorporate safety switches ⁶⁶ balances their high efficacy while minimizing potential side-effects. Altogether, the high efficacy of senolytic CAR T cells to rejuvenate intestinal fitness underscores the potential of immune-based cellular therapy to promote tissue regeneration.

334

335 LIMITATIONS OF THE STUDY

336 Our study harnesses senolytic CAR T cells to uncover the detrimental impact of senescent cell 337 accumulation on intestinal regeneration. While in vitro co-culture of aged intestinal crypts and 338 senolytic CAR T cells is enough to rejuvenate aged ISCs, it is possible that in vivo the elimination of senescent cells in other tissues also contributes to the intestinal phenotypes that we observe. 339 340 Understanding the consequences on regeneration of systemic senolysis could lead to better 341 regenerative strategies. Further studies are also needed to assess whether epithelial plasticity 342 and niche-mediated regulation of regeneration play a role in the the uPAR CAR T-mediated 343 enhancement of stem cell activity. Finally, while we identify epithelial expression of MHC-II as a 344 robust proxy for inflammaging in the aged intestine, the identity of the antigens that are presented 345 and their direct functional consequences remain to be elucidated.

388 **Resource availability**

389 Lead contact

390 Further information and requests for resources and reagents should be directed to the

391 corresponding authors, Dr.Semir Beyaz (beyaz@cshl.edu) and Dr.Corina Amor

392 (amor@cshl.edu).

393 Materials availability

394 This study did not generate new unique reagents.

395 Data and code availability

396 scRNA-seq data presented in this study will be deposited in the Gene Expression Ominus and 397 will be made publicly available upon publication. Original code will be uploaded to a publicly 398 available GitHub repository. Requests for materials should be addressed to the corresponding 399 authors.

400 Experimental model and subject details

401 Mice and drug treatments

402 All mouse experiments were approved by CSHL Internal Animal Care and Use Committee 403 (protocol number 21-4). All relevant animal use guidelines and ethical regulations were followed. 404 Mice were maintained under specific pathogen-free conditions. The following mice from The 405 Jackson Laboratory were used: 3-month-old C57BL/6J mice (000664), 18 to 20-month-old C57BL/6J mice (000664) and 6-week-old B6.SJL-Ptrc^a Pepc^b/BoyJ (CD45.1 mice) (002014). Mice 406 407 of both sexes were used at 3 months of age and 18-20 months of age for the aging experiment and females of 6-10 weeks old for T cell isolation. p16^{lnk4A}-Luciferase (B6.Cg-Cdkn2a^{tm3.1Nesh} Tyr^{c-} 408 409 ^{2J/}Nci) were obtained from the NCI mouse repository (strain O1XBT). p16^{Ink4A}-Luciferase mice between 2-16 months of age were used and monitored by bioluminescence imaging with luciferin 410 411 (Goldbio) using the IVIS imaging system (PerkinElmer) with Living Image software (PerkinElmer). 412 For abdominal irradiation experiments, mice were irradiated locally once with 15Gy in the 413 abdomen with the help of a lead protector device covering the rest of the body. For DSS 414 administration, dextran sulfate sodium salt M.W.36000-50000 colitis grade (MP biomedicals; 415 0216011090) was administered in drinking water at 2% for 9 days. For Edu administration, Edu 416 (Thermo Fisher Scientific; A10044) was injected at 0.5 mg/kg 4 hours before euthanasia as described ⁵². For adoptive T cell transfer mice were treated with one intraperitoneal injection of 417 cyclophosphamide 200mg/kg (Sigma;C0768) 18h before T cell injection as described ²⁷. 418 419 Ovalbumin-Texas red (Thermo Fisher Scientific;O23021) was administered by oral gavage at 420 1mg/kg 1 hour before euthanasia as described ⁶⁷. Immunization with ovalbumin was performed 421 by administering 1mg OVA (Sigma; A7641) by oral gavage three times at 1 week intervals as 422 described in ⁶⁸. Mice were kept in group housing. Mice had free access to food and water and 423 were fed (PicoLab Rodent Diet 20, LabDiet). Mice were randomly assigned to the experimental 424 groups.

425 Methods details

426 Intestinal crypt isolation and flow cytometry

427 As previously reported ^{9,52}, small intestine was removed, washed with cold PBS-/-, opened 428 laterally and cut into 3-5mm fragments. Pieces were washed multiple times with ice cold PBS-/-429 until clean, washed 2-3 with PBS/EDTA (7.5mM), and incubated with mild agitation for 30 minutes 430 at 4C. Crypts were then mechanically separated from the connective tissue by shaking, and 431 filtered through a 70-µm mesh into a 50 mL conical tube to remove villus material and tissue 432 fragments. Crypts were removed from this step for crypt culture experiments and embedded in 433 Matrigel[™] (Corning 356231 growth factor reduced) with crypt culture media. For Epcam⁺ cell 434 isolation, the crypt suspensions were dissociated to individual cells with TrypLE Express (Thermo 435 Fisher Scientific, 12604039) and stained for flow cytometry. Epithelial cells were isolated as 436 SYTOX⁻, CD45⁻ Epcam⁺ with a BD FACS Aria II SORP cell sorter into supplemented crypt culture medium for culture. uPAR+ and uPAR- populations were isolated as DAPI⁻, uPAR^{+/-} with a SONY 437 438 cell sorter(SH800S). For immune phenotyping, dissociated crypt suspensions were stained for 439 flow cytometry. For this, Fc receptors were blocked using FcR blocking reagent, mouse (Miltenyi 440 Biotec). The following fluorophore-conjugated antibodies were used: PE-uPAR (FAB531P, R&D 441 systems, lot ABLH0521021), AF700-uPAR (FAB531N, R&D systems, lot AFNL0122081), BV785-442 CD45.1 (110743, BioLegend, lot B319039), AF488-CD3 (100210, BioLegend, lot B364217), 443 BUV395-CD4 (563790, BD Biosciences, lot 1165066), PECy7-CD8 (100722, BioLegend, lot B282418), BV421-CD62L (104435, BioLegend, lot B283191), APCCy7-CD44 (560568, BD 444 445 Biosciences, lot 1083068), BV650-LAG3 (125227, BioLegend, lot B333220), BV510-PD1

(BioLeaend, 135241, lot B342120), BV605-CD25 (102035, BioLeaend, lot B354812), APC-446 447 Epcam (118214, Biolegend, lot B280290), FITC-CD45 (103102, BioLegend, lot 2041142), FITC-448 MHCII (11-5321-82, Invitrogen, lot 2442242), PE-CD153 (12-1531-82, Invitrogen, lot 2504402), 449 BV510-PD1 (135241, BioLegend, lot B342120), BV711-CD45.2 (109847, BioLegend, lot 450 B348415), PE-Texas red-CD28 (102124, BioLegend, lot B376397), BUV737-LRG1 (741812, BD 451 Biosciences, lot 2327039). Ghost UV 450 Viability Dye (13-0868-T100, Tonbo Biosciences lot 452 D0868083018133) or SYTOX Blue dead cell stain (Thermo Fisher Scientific, S34857; lot2491422) 453 or DAPI (Sigma, 32670-5MG-F) was used as viability dye. Flow cytometry was performed on a 454 LSRFortessa instrument (BD Biosciences), and data were analyzed using FlowJo (TreeStar).

455

456 Single cell RNA-seq

457 Two distinct single cell RNA-seq experiments were conducted: one that assessed the effects of 458 CART-cell treatment on young and old mice and one that analyzed sorted uPAR positive or 459 negative cells from aged intestines. In the CAR T-cell treatment dataset a total of 4 replicates per 460 treatment groups (uPAR & UT) with stratified sampling of age and sex (2 males and 2 females 461 per age and treatment group). For the uPAR positive or negative dataset there were 2 replicates including 2 females and 2 males. Single cell datasets for each experiment were independently 462 assessed for data guality following the guidelines described by^{69,70}. Cells with more than 15% 463 464 mitochondrial transcripts as well as cells that had fewer than 100 feature counts or expressed 465 fewer than 2000 genes were removed. After QC, Seurat (v4.0.3,⁷¹) was used for normalization, 466 graph-based clustering and differential expression analysis. Each dataset was normalized using 467 SCTransform and the 2500 most variable genes were identified with SelectIntegrationFeatures. 468 All samples were integrated into a singular dataset via using the PrepSCTIntegration, 469 FindIntegrationAnchors, and IntegrateData functions⁷². MAGIC imputation was conducted on integrated data to impute missing values and account for technical noise⁷³. RunPCA was 470 471 implemented on the integrated datasets to identify the top 15 principal components (PCs) that

472 were used for UMAP analysis and clustering. Louvain clustering at a resolution of 1 was implemented. Clusters were labeled in accordance with expression levels of intestinal epithelial 473 subtype signatures identified by³². Senescent cells were identified by first creating metagene 474 scores for senescence using the signatures described by²⁵. Cells expressing the metagene 475 476 signature greater than the apex of the distribution of expression were deemed to be senescent. 477 Differential expression analysis was conducted using the FindMarkers function with the MAST method to evaluate differences within the transcriptome ⁷⁴. Wilcoxon rank-sum tests to determine 478 479 if gene expression was significant was conducted using the *wilcox.test* function in stats (v4.1.0, 480 (R Core Team, 2021)).

481

482 Organoid culture for crypts and isolated cells

483 Isolated crypts were counted and embedded in Matrigel[™] (Corning 356231 growth factor 484 reduced) at 5–10 crypts per ul and cultured in a modified form of medium as described previously ⁷⁵. Unless otherwise stated, Advanced DMEM (Thermo Fisher Scientific, 12491023) with 10% 485 486 Penicillin:Streptomycin (GeminiBio, 400-109) was supplemented by EGF 40 ng ml⁻¹ (Peprotech, 487 315-09), Noggin 50 ng ml⁻¹ (Peprotech, 250-38), R-spondin 62.5 ng ml⁻¹ (Peprotech, 315-32), N-488 acetyl-L-cysteine 1 µM (Sigma-Aldrich, A9165), N2 1X (Gibco, 17502-048), B27 1X (Gibco, 489 17504-044), Chiron 10 µM (LC Laboratories, C-6556), Y-27632 dihydrochloride monohydrate 20 ng ml⁻¹ (Sigma-Aldrich, Y0503). 25 µL drops of Matrigel[™] with crypts were plated onto a flat 490 491 bottom 48-well plate (Corning 3524) and allowed to solidify for 5-6 minutes in a 37°C incubator. 492 Five hundred microliters of crypt culture medium were then overlaid onto the Matrigel[™], changed 493 every other day, and maintained at 37°C in fully humidified chambers containing 5% CO₂. 494 Clonogenicity (colony-forming efficiency) was calculated by plating 50-300 crypts per well and 495 assessing organoid formation 3-7 days or as specified after initiation of cultures. Organoids were propagated as previously described ^{9,52}. For secondary subculture experiments, primary 496 497 organoids were separated for a duration of 6 minutes using TrypLE Express (Thermo Fisher

Scientific, 12604039) at a temperature of 37°C. The resulting dissociated single cells were counted and plated equally in Matrigel, and left to solidify. The culture medium was refreshed every other day with fresh crypt media, and the organoids were maintained at 37°C in a fully humidified chamber with 5% CO2.

502

503 Histological analysis

504 Tissues were fixed overnight in 10% formalin, embedded in paraffin and cut into 5-µm sections. 505 Sections were subjected to hematoxylin and eosin (H&E) staining. Immunohistochemical staining 506 was performed following standard protocols. The following primary antibodies were used: uPAR 507 (AF534, R&D systems, lot DCL0622021) and Caspase 3 (9664S, Cell Signaling Technology, lot 508 22). The following secondary antibodies were used: HRP Horse anti-goat IgG (MP-7405, Vector 509 Laboratories, lot ZJ0718), HRP Horse anti-rabbit IgG (MP-7401, Vector Laboratories, lot ZH0609) 510 and AF488-donkey Anti rabbit IgG (A21206, Invitrogen, 2376850). For detection of EdU the ClickiT[™] Plus EdU Alexa Fluor[™] 647 Imaging Kit (Thermo Fisher, C10640) was used. 511

512

513 <u>SA- β -Gal staining</u>

514 SA- β -gal staining was performed as previously described⁷⁶ at pH 5.5 for mouse tissues. 515 Specifically, fresh frozen tissue sections were fixed with 0.5% glutaraldehyde in phosphate-516 buffered saline (PBS) for 15 min, washed with PBS supplemented with 1 mM MgCl₂ and stained 517 for 5–8 h in PBS containing 1 mM MgCl₂, 1 mg ml⁻¹ X-gal, 5 mM potassium ferricyanide and 5 518 mM potassium ferrocyanide. Tissue sections were counterstained with eosin. Three fields per 519 section were counted with ImageJ and averaged to guantify the percentage of SA-β-gal+ area 520 per field. For the fluorescent SA- β -gal labelling, tissue slides were exposed to the C12RG 521 substrate at 37°C according to manufacturer's instructions (ImaGene Red C12RG lacZ Gene 522 Expression Kit, Molecular Probes, I2906)^{77,78}. Subsequently, for IF analysis, slides were fixed with 523 4% PFA for 10 minutes at room temperature and proceed with regular IF as performed following

standard protocols and previously described²⁷. The following antibodies were used: anti-mouse
uPAR (R&D, AF534, 1:100)

526

527 *In situ* hybridization

528 Single-molecule *in situ* hybridization was performed to detect Plaur (mouse: 448731; human:

529 542701) and Cdkn2a (mouse: 411011-C2; human 310282-C2) using Advanced Cell Diagnostics

530 RNAscope 2.5 HD Detection Kit following manufacturer's instructions.

531

532 <u>Human samples</u>

533 De-identified human samples from colonoscopy biopsies of patients (males and females between 534 56 and 89 years of age) with a diagnosis of colon adenocarcinoma were obtained through the 535 Northwell Health Biospecimen Repository. All human studies complied with all relevant guidelines 536 and ethical regulations and were approved by the Institutional Review Board at Northwell Health 537 (Protocol number IRB20-0150).

538

539 Intestinal permeability assay

Mice were fasted for 6 hours before starting the test and a pre-test plasma sample was collected after this time. Subsequently, mice were administered by oral gavage 150ul of 80mg/ml FITC-Dextran (4kDa) (Sigma-Aldrich; FD4-250mg). Plasma sample collection was repeated 4 hours post-gavage. The pre and post plasma samples were diluted 1:10 in PBS and a total volume of 100ul transferred to a black 96 well plate. Pre and post plasma fluorescence levels were determined in a plate reader at 530nm with excitation at 485nm.

546

547 Isolation, expansion and transduction of mouse T cells

548 B6.SJL-Ptrc^a Pepc^b/BoyJ(CD45.1 mice) were euthanized and spleens were collected. After tissue 549 dissection and red blood cell lysis, primary mouse T cells were purified using the mouse Pan T

cell Isolation Kit (Miltenvi Biotec: 130-095-130). Purified T cells were cultured in RPMI-1640 550 (Invitrogen; 11-875-085) supplemented with 10% FBS (Corning; 35-010-CV), 10 mM HEPES 551 552 (Thermo Scientific; 15630080), 2 mM L-glutamine (Thermo Scientific; 25030164), MEM non-553 essential amino acids 1x (Thermo Scientific; 11140076), 55 μM β-mercaptoethanol (Thermo 554 Scientific; 21985023), 1 mM sodium pyruvate (Thermo Scientific; 11360070), 100 IU ml⁻¹ 555 recombinant human IL-2 (Proleukin; Novartis) and mouse anti-CD3/28 Dynabeads (Gibco; 556 11452D) at a bead:cell ratio of 1:2. T cells were spinoculated with retroviral supernatant collected 557 from Phoenix-ECO cells 24 h after initial T cell activation as described ^{79,80} and used for functional 558 analysis 3-4 days later.

559

560 Genetic modification of T cells

The mouse SFG γ-retroviral m.uPAR-m28z plasmid has been described ²⁷ and was obtained from Memorial Sloan Kettering Cancer Center. In this construct the anti-mouse uPAR scFv is preceded by a mouse CD8A leader peptide and followed by the Myc-tag sequence (EQKLISEEDL), mouse CD28 transmembrane and intracellular domain and mouse CD3z intracellular domain ^{79,80}. A plasmid encoding the SFGγ retroviral vector were used to transfect gpg29 fibroblasts (H29) to generate VSV-G pseudotyped retroviral supernatants, which were used to construct stable retrovirus-producing cell lines as described ^{79,81}.

568

569 Antigen presentation experiments

Were performed as described in ⁵³. In brief, 5x10³ sort purified CD45⁻ Epcam⁺uPAR⁺ or uPAR⁻ cells were cultured with 5x10⁴ OT-II T cells in the organoid culture medium described above (without Matrigel), with or without 15ug/ml ovalbumin peptide (Anaspec; AS-27024) at 37C for 72h. T cell proliferation was assessed using the CellTrace Violet proliferation kit (Thermo Fisher Scientific, C34557) per manufacturer's instructions.

575

576 Detection of Granzyme B or IgA levels

577 Levels of granzyme B, total IgA or anti-OVA IgA from mouse plasma were evaluated by enzyme-

578 linked immunosorbent assay (ELISA) according to the manufacturer's protocols (Abcam;

- ab238265) granzyme B, (Abcam; ab157717) total and (Chondrex, 3018) anti-OVA.
- 580

581 <u>Taxonomic microbiota analysis/Metagenomics</u>

582 Metagenomics sequencing analysis of fecal samples was performed by Transnetyx (Cordova,

583 TN) as described ⁸². Briefly, fresh mouse fecal samples were placed in barcoded sample collection

tubes containing DNA stabilization buffer and shipped to Transnetyx where DNA extraction, library

585 preparation, sequencing, and the initial analysis were performed. Raw data files were uploaded

to One Codex analysis software.

587

588 Quantification and statistical analysis

589 Unless specified statistical analysis was performed using GraphPad Prism v.6.0 or 7.0 (GraphPad

590 software). Flow cytometry data was analyzed with FlowJo 10.8.1 (FlowJo LLC). Images were

analyzed with Image J-Fiji (NIH). No statistical methods were used to predetermine sample size

- 592 in the mouse studies, and mice were allocated at random to treatment groups. Figures were
- 593 prepared using BioRender.com for scientific illustrations and Illustrator CC 2022 (Adobe).

802 FIGURES

803

Figure 1

805 correlate with decreased intestinal fitness.

806 **(A)** Representative SA-β-gal staining of proximal jejunum of young (3 months) and old (20 807 months) mice and quantification (right) (n=3 per group).

808 (B) Representative co-immunofluorescence pictures showing levels of *Plaur* and *Cdkn2a* in

proximal jejunum of young (3 months) and old (20 months) mice through RNA in situ hybridization.

810 (n=3 per group)

811 (C) Cell surface uPAR expression as determined by flow cytometry on isolated intestinal crypts

from young (3 months) and old (20 months) mice. (n=3 per group).

813 (D) Percentage of surface uPAR positive cells that are either Epcam positive or CD45 positive as

determined by flow cytometry on isolated intestinal crypts from young (3 months) and old (20

815 months) mice. (n=3 per group).

816 (E) Representative co-immunofluorescence of SA- β -gal and uPAR staining in the proximal

817 jejunum of 20 month old mice (n=3).

818 (F-G) uPAR+ and uPAR- cells from isolated intestinal crypts from old (20 months old) mice were

819 FACS sorted and subjected to scRNAseq (n=4 mice per group).

(F) Uniform manifold approximation and projection (UMAP) visualization of small intestinal cell

types generated by 10X chromium protocol. Color scale indicates differences in density of cellular

822 populations between $uPAR^+$ and $uPAR^-$ cells.

(G) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
scale indicates log2FC change in senescence signature³³ between uPAR⁺ and uPAR⁻ cells. Right:
quantification of the proportion of uPAR⁺ and uPAR⁻ cells contributing to the senescence
signature.

(H) UMAP visualization of small intestinal cell types in young (25-30 years old) and old (65-70
years old) subjects generated by 10X chromium protocol. Color scale indicates log2FC change in
senescence signature³³ between old versus young. Right: quantification of the proportion of old
and young cells contributing to the senescence signature.

(I) Split-violin plot indicates the expression level *PLAUR* in the intestinal stem cell and epithelial
lineage of young (25-30 years old) and old (65-70 years old) subjects generated by 10X chromium
protocol. Boxplots display median (center line) and interguartile range (box).

(J) Representative immunofluorescence pictures showing levels of *PLAUR* and *CDKN2A* in
samples from the intestine of middle aged (56 years old) and old (89 years old) humans through
RNA in situ hybridization.

(K) Correlation between luciferase levels as measured by average radiance in p16^{Luc} mice with
the levels of FITC-dextran in plasma 4h after oral administration. Solid and dotted lines show
linear regression and 95% confidence interval. (n=20).

840 (L) Secondary organoid formation capacity of crypts from mice with low levels of p16Luc (<20.000

p/s/cm²/sr average radiance) or high levels of p16Luc (>20.000 p/s/cm²/sr average radiance) (n=2

842 mice per group, 8 replicates per mouse) quantification at day 3, representative brightfield images

843 of day 4 secondary organoids.

844 (M) Principal coordinate analysis (PCoA) of the microbial composition in feces of mice with low

levels of p16 (average radiance < 20.000 p/s/cm²/sr, n=6) and of feces from mouse with high

levels of p16 (average radiance > $20.000 \text{ p/s/cm}^2/\text{sr}, n=5$).

(A-M) results of 1 independent experiment. (C-D, L) Data are mean ± s.e.m. (C-D, L) Two-tailed
unpaired Student's t-test. (I) Wilcoxon rank sum test. *P<0.05,**P<0.01, ***P<0.001,
****P<0.0001. (K) Pearson correlation coefficient.

Fig. 2.Senolytic uPAR targeting CAR T cells rescue intestinal epithelium integrity in aging and injury.

- 863 (A-E) Young (3 months) and old (18 months) mice were treated with 0.5x10⁶ untransduced T
- cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). Mice were harvested 6 weeks after infusion.
- (A) Percentage of CD45.1 and CD3 double positive cells in the intestinal crypts. (n=8 per group).
- 866 **(B)** Representative immunohistochemistry staining of uPAR and SA-b-gal staining of proximal
- 867 jejunum.
- (C) Percentage of histological area with uPAR positive cells per field as determined by
 immunohistochemistry in the proximal jejunum (n=5 for UT and m.uPAR-m.28z young; n=5
 m.uPAR-m.28z old; n=4 for UT old).
- (D) Percentage of histological area with SA- β -gal positive cells in the proximal jejunum (n=5 for
- UT and m.uPAR-m.28z young; n=5 m.uPAR-m.28z old; n=4 for UT old).
- (E) Plasma levels of FITC-Dextran 4 hours after oral gavage. (n=11 for UT and m.uPAR-m.28z
- young; n=14 for UT old; n=15 for m.uPAR-m.28z old).
- 875 (F-J) Young (3 months) and old (18 months) mice were infused with 0.5x10[^]6 untransduced T
- cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). 15 days after cell injection mice were subjected
- to abdominal irradiation with 15Gy. Mice were harvested 6 days after irradiation.
- (F) Fold change in weight before and after abdominal irradiation with 15Gy. (D= day). (n=10 pergroup).
- (G) Plasma levels of FITC-Dextran 4 hours after oral gavage. (n=9 per group).
- (H) Representative immunofluorescence staining of Epcam (green), EdU (red) and DAPI (blue)
- and immunohistochemistry of Caspase 3 of proximal jejunum.
- (I) Quantification of number of EdU positive cells per intestinal crypt in samples from (I).(n=4 for
- UT young, n=5 m.uPAR-m.28z young, n=5 UT old, n=4 m.uPAR-m.28z old).
- (J) Quantification of number of Caspase 3 positive cells per intestinal crypt in samples from (I).
- 886 (n=9 for UT and m.uPAR-m.28z young; n=8 for UT and m.uPAR-m.28z old).

887	(K-M) Young (3 months) mice were infused with 0.5x10^6 untransduced T cells (UT) or uPAR
888	CAR T cells (m.uPAR-m.28z). 20 days after cell injection mice were subjected to continuous
889	drinking water with 2% of DSS. Mice were harvested 9 days after the start of DSS administration.
890	(K) Fold change in weight before and after DSS administration. (D= day). (n=5 per group).
891	(L) Ratio of colon weight (g) to colon length (cm) at day 9 of DSS administration. (n=5 per group).
892	(M) Representative hematoxylin and eosin (H&E) staining of colons at day 9 of DSS
893	administration.
894	(A-J) results of 2 independent experiments. (K-M) results of 1 independent experiment. (A, C-G,I-

916 Fig. 3. uPAR CAR T cells rejuvenate intestinal stem cells *in vivo* and *in vitro*.

- 917 (A-H) Young (3 months) and old (18 months) mice were treated with 0.5x10⁶ untransduced T
- 918 cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). Mice were harvested 6 weeks after infusion.
- 919 (A) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
- scale indicates difference in localized cellular density between UT treated old and young mice.
- 921 (n=4 mice per group).
- 922 **(B)** Fraction of cells for each of the different cell types shown in (A) in UT treated old and young
- 923 mice (n=4 mice per group). Error bars represent s.e.m.
- 924 (C) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
- scale indicates log2FC differences in stemness signature score between UT treated old and
- 926 young mice (n=4 mice per group).
- 927 (D) Split-violin plot indicates the expression level of 6 different stem-related genes in the stem
- 928 cells from UT treated old and young mice. (n=4 mice per group). Boxplots display median (center
- 929 line) and interquartile range (box).
- 930 (E) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
- 931 scale indicates difference in localized cellular density between uPAR and UT CAR T treated old932 mice. (n=4 mice per group).
- 933 **(F)** Fraction of cells for each of the different cell types shown in (E) in old mice treated with UT or
- 934 uPAR CAR T cells. (n=4 mice per group). Error bars represent s.e.m.
- (G) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
 scale indicates log2FC differences in stemness signature score between uPAR CAR T and UT
 treated old mice. (n=4 mice per group).
- 938 (H) Split-violin plot indicates the expression level of 6 different stem-related genes in the stem
- 939 cells from old UT and uPAR CAR T treated mice. (n=4 mice per group). Boxplots display median
- 940 (center line) and interquartile range (box).

- 941 (I-K) Young (3 months) and old (18 months) mice were treated with 0.5x10⁶ untransduced T
- 942 cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). Mice were harvested 8 weeks after infusion and
- 943 organoids were generated from their crypts.
- 944 (I-J) Organoid initiating capacity of crypts from young or old, UT or uPAR CAR T treated mice
 945 (n=2 mice per group, 6 replicates per mouse). (I) Representative images of day 5 secondary
 946 organoids. (J) Number of secondary organoids on day 4 per dissociated crypt-derived primary
 947 organoid.
- 948 **(K)** Organoid initiating capacity on day 4 of sorted Epcam+ cells from the intestinal crypts of young
- and old, UT or uPAR CAR T treated mice (n=4 mice per group).
- 950 **(L)** UMAP visualization of murine small intestinal cell types generated by 10X chromium protocol.
- 951 Color scale indicates log2FC differences in stemness signature score between mouse uPAR
- 952 positive and uPAR negative cells. (n=4 mice per group).
- 953 (M) Split-violin plot indicates the expression level of 6 different stem-related genes in mouse uPAR
- 954 positive or uPAR negative stem cells. (n=4 mice per group). Boxplots display median (center line)
- 955 and interquartile range (box).
- 956 (N) UMAP visualization of human small intestinal cell types generated by 10X chromium protocol.
- 957 Color scale indicates log2FC differences in stemness signature score between human *PLAUR*
- 958 positive and *PLAUR* negative cells. (n=4 mice per group).
- 959 (O) Split-violin plot indicates the expression level of 5 different stem-related genes in human
 960 *PLAUR* positive or *PLAUR* negative stem cells. (n=4 mice per group). Boxplots display median
 961 (center line) and interguartile range (box).
- 962 **(P-S)** Intestinal crypts from young (3 months) and old (20 months old) mice were isolated and 963 seeded to form organoids together with either UT or m.uPAR-m28z cells at 1:10 effector:target 964 ratio. 72h later equal numbers of secondary organoids were generated per dissociated crypt-965 derived primary organoids.

- 966 (P) Representative images of organoids and UT or m.uPAR-m28z CAR T cell co-culture. (n=8
- 967 replicates).
- 968 (Q) Quantification of the percentage of dead organoids per field 72h after co-culture between
- 969 organoids and UT or m.uPAR-m28z CAR T cells. (n= 8 replicates).
- 970 (R) Representative images of secondary organoids from young and old in vitro UT or m.uPAR-
- 971 m28z CAR T cell treated primary organoids. (n=12 replicates).
- 972 (S) Quantification of number of secondary organoids on day 4. (n=12 replicates).

992 Fig. 4. Senescent cells drive chronic age-related intestinal inflammation.

(A) Split-violin depicting the log2 fold change in the levels of key genes in the inflammatory
response signature across cell types in old UT mice versus young UT infused mice 6 weeks post
infusion. (n=4 mice per group). Boxplots display median (center line) and interquartile range (box).
(B) Dotplot indicates the expression level of the different genes of the inflammatory response
signature for the different cell types in old UT mice versus young UT infused mice 6 weeks after
infusion. (n=4 mice per group).

999 (C) Split-violin depicting the log2 fold change in the levels of key genes in the inflammatory
1000 response signature across cell types in old uPAR CAR T treated mice versus old UT infused mice
1001 6 weeks post infusion. (n=4 mice per group). Boxplots display median (center line) and
1002 interguartile range (box).

(D) Dotplot indicates the expression level of the different genes of the inflammatory response
 signature for the different cell types in old uPAR CAR T treated mice vs old UT infused mice 6
 weeks after infusion. (n=4 mice per group).

(E) Percentage of cells expressing surface MHC-II as determined by flow cytometry on CD45⁻
Epcam⁺ uPAR⁻ or uPAR⁺ cells on isolated intestinal crypts from old (18 months old) mice. (n=4 per
group).

(F) Split-violin plot indicates the expression level of MHC-II signature score in epithelial and stem
 PLAUR- or *PLAUR+* cells from the ileum of young (25-30 years old) and old (65-70 years old)
 subjects. Boxplots display median (center line) and interquartile range (box).

(G) 18 months old mice were administered 1mg/ml ovalbumin conjugated to Texas red by oral
gavage. Intestinal crypts were isolated and dissociated 1h after administration. Graph depicting
percentage of cells CD45⁻ Epcam⁺ uPAR⁻ or uPAR⁺ cells positive for Texas red. (n=8 mice per
group).

(H) CD45⁻ Epcam⁺ uPAR⁺ cells induce CD4⁺ T cell proliferation *in vitro*. Representative FACS
 histograms of cell trace violet-labeled CD4⁺ T cells from OT-II mice that were cultured alone or

- 1018 with CD45⁻ Epcam⁺ uPAR⁻ or CD45⁻ Epcam⁺ uPAR⁺ cells from 18 month old mice with or without
- 1019 15ug/ml of OVA323-339. Values shown are mean \pm s.d. (n=4 mice per group).
- 1020 (I) Percentage of senescent endogenous T cells (CD153+PD1+) from CD4+CD44+CD62L- T cells
- in the intestinal crypts of young and old mice 6 weeks after cell infusion. (n=4 per group).
- 1022 (J) Percentage of senescent endogenous T cells (CD28- KLRG1+) from total CD45.2+ CD3+ cells
- in the intestinal crypts of young and old mice 6 weeks after cell infusion. (n=4 per group).
- 1024 (JK Serum levels of total unspecific IgA in young and old mice 20 days after cell infusion (young
- 1025 UT n=5, young uPAR n=5, old UT n=6 mice, old uPAR n=7 mice).
- 1026 (L) Young (3m) and old (20m) mice were infused with 0.5x10⁶ UT or m.uPAR-m.28z CAR T cells.
- 1027 20 days after infusion, mice were immunized by oral gavage with OVA and cholera toxin on three
- 1028 occasions separated by 7 days. Serum was collected on day 21 and levels of specific anti OVA
- 1029 IgA were determined by ELISA. (Young UT n=5, young uPAR n=5, old UT n=4 mice, old uPAR1030 n=5 mice).
- (M) Principal coordinate analysis (PCoA) of the microbial composition in in fecal samples of young
 (3m) and old (20m) mice 20 days after infusion with 0.5x10⁶ UT or m.uPAR-m.28z CAR T cells
 (n=5 mice per group).
- (**N**) Summary of the key points of our findings. Senescent cells (blue) of different lineages accumulate in the small intestine with age. They express surface uPAR (red molecule). Senescent cells lead to decreased intestinal fitness characterized by reduced ISC activity and decreased epithelial barrier integrity. Through expression of MHC-II molecules, senescent cells contribute to chronic immune activation and mucosal immune senescence. Treatment with anti-uPAR CAR T cells eliminates senescent cells and rejuvenates the overall fitness of the small intestine.
- 1040 (A-F, H-M) results of 1 independent experiment. (G) results of 2 independent experiments. (E,G,
 1041 I-L) Data are mean ± s.e.m. (H) Data are mean±s.d. (A,C,F) Wilcoxon rank sum test
 1042 *P<0.05.**P<0.01. ***P<0.001. ****P<0.0001. (B, D, E,G, I-L) Two-tailed unpaired Student's t-test.

1044

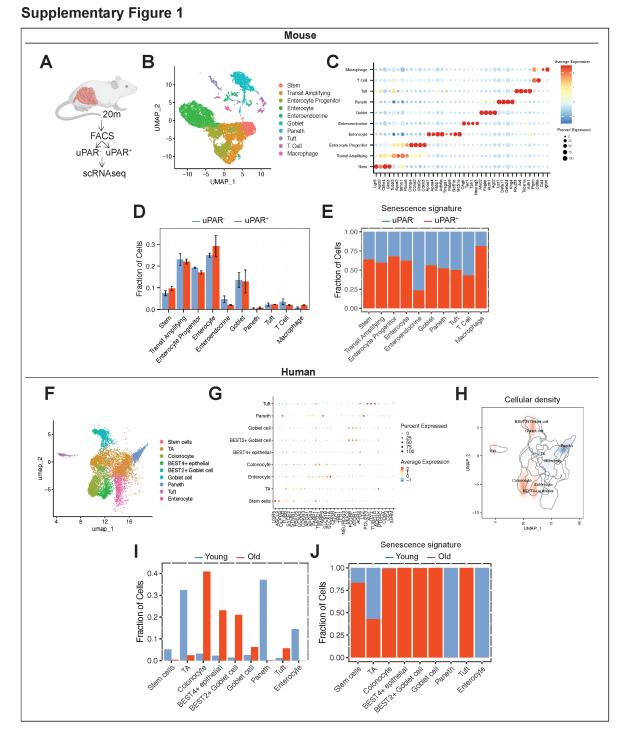

Figure S1. Age-dependent accumulation and characteristics of uPAR⁺ senescent cells in
murine and human small intestines. Related to Figure 1.

(A) Experimental scheme for (B-F and Fig.1F-G). uPAR⁺ and uPAR⁻ cells from isolated intestinal
crypts from old (20 months old) mice were FACS sorted and subjected to scRNAseq (n=4 mice
per group).

(B) Uniform manifold approximation and projection (UMAP) visualization of small intestinal cell
 types generated by 10X chromium protocol. Colors indicate the 10 different intestinal epithelial
 lineages.

(C) Dot plot showing the 40 signature gene expressions across the 10 lineages. The size of theB)
 dots represents the proportion of cells expressing a particular marker, and the color scale
 indicates the mean expression levels of the markers (log1p transformed).

(D) Bar graph representing the fraction of cells in each of the 10 different populations on uPAR⁺
 and uPAR⁻ cells from isolated intestinal crypts from old (20 months old) mice. Error bars represent

1060 s.e.m.

(E) Quantification of the proportion of uPAR⁺ and uPAR⁻ cells by cell type contributing to the
senescence signature in Fig.1G.

(F) UMAP visualization of human ileal cell types generated by 10X chromium protocol. Colorsindicate the 9 different intestinal epithelial lineages.

(G) Dot plot showing the 33 signature gene expressions across the 9 lineages. The size of the
 dots represents the proportion of cells expressing a particular marker, and the color scale
 indicates the mean expression levels of the markers (log1p transformed).

(H) UMAP visualization of human ileal cell types generated by 10X chromium protocol. Color scale
 indicates differences in density of cellular populations between old (65-70 years old) and young
 (25-30 years old) subjects.

(I) Bar graph representing the fraction of cells in each of the 9 different populations on ileal cells
 from young (25-30 years old) and old (65-70 years old) subjects.

1073 (J) Quantification of the proportion old and young cells by cell type contributing to the senescence

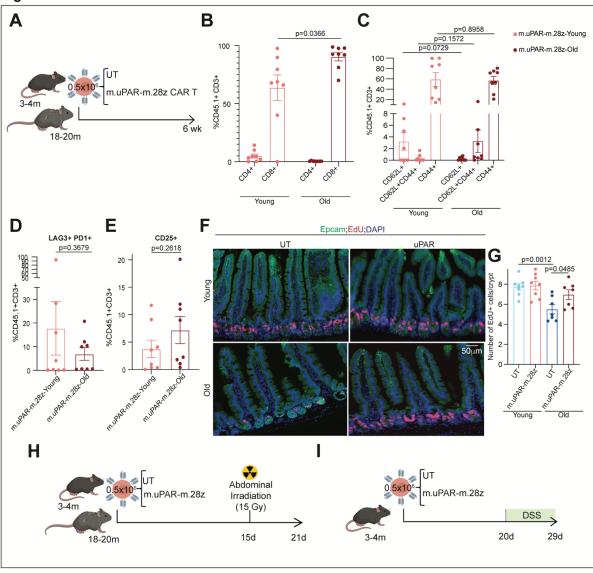

signature in (Fig.1H).

- 1075 (A-J) results of 1 independent experiment.

1118 FIGURE S2 (RELATED TO FIGURE 2)

1119

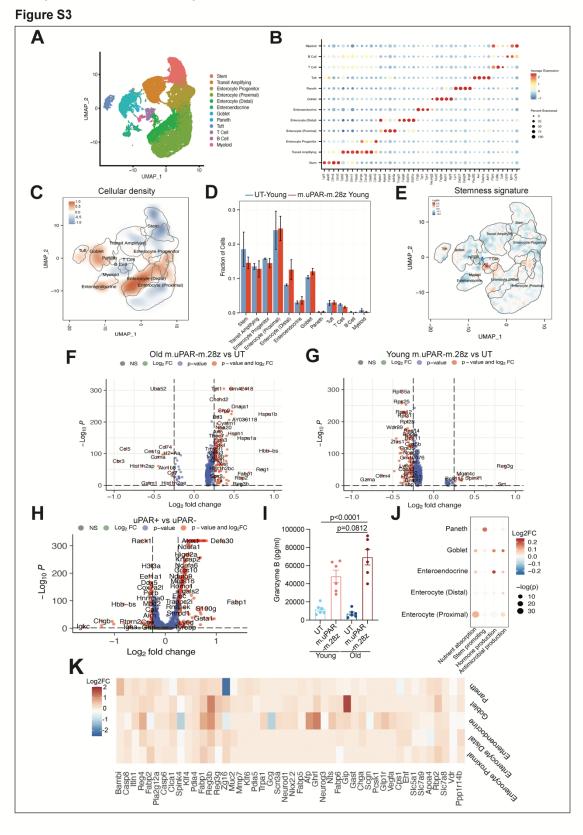

- 1123 intestine. Related to Figure 2.
- (A) Experimental scheme for (Figure 2A-E and S2B-G). Young (3 months) and old (18-20 months)
- mice were treated with 0.5x10⁶ untransduced T cells (UT) or uPAR CAR T cells (m.uPAR-m.28z).
- 1126 Mice were harvested 6 weeks after infusion.

- (B) Percentage of CD4 positive or CD8 positive cells from CD45.1 and CD3 double positive cells
- in the intestinal crypts. (n=8 per group).
- (C) Percentage of CD62L, CD44 and CD62L and CD44 positive cells from CD45.1 and CD3
- 1130 double positive cells in the intestinal crypts. (n=8 per group).
- (D) Percentage of LAG3 and PD1 positive cells from CD45.1 and CD3 double positive cells in the
- 1132 intestinal crypts. (n=8 per group).
- (E) Percentage of CD25 positive cells from CD45.1 and CD3 double positive cells in the intestinal
- 1134 crypts. (n=8 per group).
- 1135 (F) Representative immunofluorescence staining of Epcam (green), EdU (red) and DAPI (blue) of
- 1136 proximal jejunum.
- 1137 (G) Quantification of number of EdU positive cells per intestinal crypt in samples from (J).(n=8 for
- 1138 UT and m.uPAR-m.28z young and n=7 for UT and m.uPAR-m.28z old).
- (H) Experimental scheme for (Figure 2F-J and S2I). Young (3 months) and old (18 months) mice
- 1140 were infused with 0.5x10⁶ untransduced T cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). 15
- 1141 days after cell injection mice were subjected to abdominal irradiation with 15Gy. Mice were
- 1142 harvested 6 days after irradiation.
- 1143 (I) Experimental scheme for (Figure 2K-M). Young (3 months) mice were infused with 0.5x10⁶
- 1144 untransduced T cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). 20 days after cell injection mice
- 1145 were subjected to continuous drinking water with 2% of DSS. Mice were harvested 9 days after
- 1146 the start of DSS administration.
- 1147 (B-E) results from 2 independent experiments. (F-G) results from 1 independent experiment. (B-
- 1148 E, G) Data are mean ± s.e.m. (B-E, G) two-tailed unpaired Student's t-test.

1155 FIGURE S3 (RELATED TO FIGURE 3)

1157 Figure S3. Effect of uPAR-targeting CAR T cells on intestinal crypts. Related to Figure 3.

- 1158 (A-G) Young (3 months) and old (18-20 months) mice were treated with 0.5x10⁶ untransduced
- 1159 T cells (UT) or uPAR CAR T cells (m.uPAR-m.28z). Mice were harvested 6 weeks after infusion.
- (A) UMAP visualization of small intestinal cell types in young (3 months old) and old (20 months
- 1161 old) mice treated with 0.5x10⁶ untransduced T cells (UT) or uPAR CAR T cells (m.uPAR-m.28z)
- generated by 10X chromium protocol. Colors indicate the 12 different identified populations.
- (B) Dot plot showing the 40 signature gene expressions across the 12 cellular clusters. The size
- 1164 of the dots represents the proportion of cells expressing a particular marker, and the color scale
- 1165 indicates the mean expression levels of the markers (log1p transformed).
- 1166 (C) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
- 1167 scale displays differences in cellular density of the different populations between uPAR and UT
- 1168 CAR T treated young mice (n=4 mice per group).
- 1169 (D) Fraction of cells for each lineage depicted in (A) for young mice treated with UT or uPAR CAR
- 1170 T cells. (n=4 mice per group). Error bars represent s.e.m.
- (E) UMAP visualization of small intestinal cell types generated by 10X chromium protocol. Color
 scale indicates log2FC difference in stemness signature score between uPAR CAR T and UT
 treated young mice. (n=4 mice per group).
- (F) Volcano plot of differentially expressed genes between old mice treated with UT or uPAR CAR
 T cells. (n=4 mice per group).
- (G) Volcano plot of differentially expressed genes between young mice treated with UT or uPAR
- 1177 CAR T cells. (n=4 mice per group).

(H) Volcano plot of differentially expressed genes between uPAR⁺ and uPAR⁻ cells. (n=4 mice per
group).

- 1180 (I) Levels of granzyme B 72h after co-culture between organoids and UT or m.uPAR-m28z CAR
- 1181 T cells. (n= 6 replicates).
- (J) Bubble plot showing Log2 fold change in the functional scores for the different terms across
- 1183 Paneth, goblet, enteroendocrine and enterocytes of old mice treated with UT or uPAR CAR T
- 1184 cells. (n=4 mice per group).
- 1185 (K) Heatmap representing log 2FC in gene expression between old uPAR and old UT treated1186 mice from (I).

(A-H, J-K) results of 1 independent experiment. (I) results of 2 independent experiments. (I) twotailed unpaired Student's t-test. (F-H) MAST method.
