## Abstract

We demonstrate a simple, robust, and low-cost method for producing the PURE cell-free transcription-translation system. Our OnePot PURE system achieved a protein synthesis yield of 156  $\mu\text{g}/\text{mL}$  at a cost of 0.09 USD/ $\mu\text{L}$ , leading to a 14-fold improvement in cost normalized protein synthesis yield over existing PURE systems. The OnePot method makes the PURE system easy to generate and allows it to be readily optimized and modified.

## INTRODUCTION

Cell-free transcription-translation systems have become popular for molecular engineering [1–6]. Cell-free systems can be categorized into two main classes: cell extract and recombinant systems. Cell extracts are highly functional but complex and undefined cell-free systems. In 2001, Shimizu *et al.* demonstrated that a defined cell-free system called the “PURE” system (protein synthesis using recombinant elements) could be reconstituted from purified recombinant components [7]. Because of its defined and minimal nature, PURE is an appealing choice for biological systems engineering. The PURE system has been used for genetic network engineering [2], recombinant DNA replication [8], molecular diagnostics [9], therapeutics [10], and educational kits [11]. The PURE system also represents a viable starting point for generation of an artificial cell [12, 13] and its composition has been optimized [14, 15] and extended [16] to achieve higher functionality.

Unfortunately, producing PURE is an arduous and costly process, requiring 36 individual medium to large-scale protein purifications. PURE is now commercially available (PURExpress, New England Biolabs (NEB)), but the high-cost of the commercial system at 1.36 USD/ $\mu$ L still limits its use. Although NEB provides a few different formulations of the PURE system, the commercial system can’t be customized or optimized by the user, and the precise formulation of the commercial PURE system is not publicly available. It was recently demonstrated that the PURE system could be produced using synthetic microbial “consortia” (TraMOS PURE) [17], which simplified the process of making PURE by co-expressing multiple protein components in a single *E. coli* clone combined with co-culturing of multiple strains. TraMOS PURE achieved only a  $\sim$ 20% protein yield compared to the commercial PURExpress and production cost was only marginally reduced from 1.36 USD/ $\mu$ L to 0.96 USD/ $\mu$ L. An earlier approach used MAGE to His-tag most PURE protein components in their endogenous locus and co-purified them from 6 strains to generate an ensemble PURE system (ePURE) [18]. The approach led initially to only minimal protein synthesis activity, and an optimized ePURE system ultimately reached a 11% protein yield compared to the original PURE system [7].

Here we present a simple, robust, and low-cost method for producing the PURE system. Our method co-cultures and induces all 36 protein producing *E. coli* clones in a single flask followed by a single Ni-NTA purification. Our “OnePot” method produces PURE at a cost

of 0.09 USD/ $\mu$ L and a protein synthesis capacity of 156  $\mu$ g/mL, which is as high as the commercial PURE system. A single batch prepares enough proteins for a total of 15 mL of PURE which is sufficient material for  $\sim 1,500$  10  $\mu$ L reactions and can be generated in 3 days. The method produces consistent PURE across different batches and allows the optimization of individual protein components.

## RESULTS AND DISCUSSION

The PURE system consists of several different components [7], that can be separated into three main categories: proteins (transcription, translation, and energy regeneration), ribosomes, and small molecule components (salts, buffers, NTPs, creatine phosphate, and folic acid). In this work, we developed a “OnePot” method for the preparation of all 36 protein components using a single mixed co-culture and Ni-NTA affinity purification step to simplify the process and decrease the cost of the PURE system. All 36 *E. coli* expression clones are cultured individually in small volumes overnight, which are then combined to inoculate a single 500 mL culture. The mixed culture is allowed to outgrow and is induced, followed by pelleting, lysis and loading of the lysate onto a Ni-NTA column for protein purification. To keep the final cost of the PURE system as low as possible, we also prepared ribosome and energy solutions (Fig. 1a, Supplementary Fig. S1). The entire process of OnePot PURE system preparation, including protein and ribosome purification and energy solution preparation, requires 4 days with 20 hours of hands-on time (Supplementary Table S1, S2, S3). To date no method has been presented in which all PURE proteins were prepared using a single co-culture and purification step [17, 18]. Moreover, other simplified protocols resulted in low protein synthesis activity as compared to the original PURE system [17].

We explored whether it is possible to adjust the protein component ratios in the OnePot PURE system simply by varying the ratios of the inoculation culture volumes added to the mixed co-culture (Supplementary Table S4). Besides ribosomal proteins, elongation factor thermo unstable (EF-Tu) is one of the most abundant proteins in rapidly growing *E. coli* [19] and it was shown to be one of the key factors for *in vitro* protein synthesis [14]. When preparing the PURE system based on the Shimizu protocol, which we refer to as “HomeMade” PURE, we observed that small concentration differences in many of

Figure 1: OnePot PURE preparation and optimization. **(a)** All 36 PURE protein components were produced using the OnePot method, which consists of a single co-culture and a single Ni-NTA affinity purification. Different OnePot systems were produced by varying the ratio of inoculation culture EF-Tu with respect to the 35 remaining inoculation cultures, and characterized using SDS-PAGE gels and eGFP expression. **(b)** Concentration of EF-Tu in OnePot PURE reactions derived from SDS-PAGE gel analysis, as a function of relative volume ratios of the EF-Tu inoculation culture in a co-culture. Each data point represents four biological replicates (mean  $\pm$  s.d.). **(c)** *In vitro* eGFP expression activity after 3h plotted against concentration of EF-Tu in OnePot PURE reactions. Measurements on the x-axis represent biological replicates, and y-axis measurements represent four biological replicates with three technical replicates. Error bars represent s.d. **(d)** Coomassie blue-stained SDS-PAGE gel of four OnePot PURE (EF-Tu 47%) replicates. In the right panel, intensities of the different replicates are plotted with molecular weight standards (kDa). **(e)** *In vitro* eGFP expression activity after 3 h plotted against relative inoculation volume ratios of EF-Tu. Each data point represents a single biological replicate with three technical replicates; error bars represent s.d. of the technical replicates. **(f)** Time course of *in vitro* eGFP expression with OnePot PURE (EF-Tu 47%). Each line represents a technical replicate.

the protein components led to only negligible changes in protein expression yield of the PURE system (data not shown). Additionally, over 50% of the HomeMade PURE protein components consists of EF-Tu (Supplementary Table S5). Hence, we decided to optimize our OnePot PURE system with a particular focus on this translation factor.

We varied the relative volume of the EF-Tu inoculating culture with respect to the 35 remaining inoculation cultures to generate ratios of 3%, 17%, 38%, and 47%. The 3% ratio corresponds to 100  $\mu$ L of all 36 inoculation cultures, including EF-Tu, being added to the mixed co-culture (Supplementary Table S4). As can be seen from gels and corresponding analysis, larger percentages of the EF-Tu strain in the co-culture led to higher absolute levels of EF-Tu in the OnePot protein system (Fig. 1b, Supplementary Fig. S2, S3). Increased concentrations of EF-Tu also gave rise to higher protein expression yields (Fig. 1c). We could therefore show that it is possible to modify the ratio of an individual PURE protein component simply by varying the initial inoculation ratio of the corresponding strain, and

that the OnePot PURE system gave rise to high protein expression yields.

It has been thought that precise control over the PURE system composition is required to achieve reproducible, and high protein expression yields and it has been suggested that a simple one-pot method would not be a viable option for robustly generating the PURE system [17]. However, we observed that variations in overnight culture densities (Supplementary Fig. S4) did not lead to substantial differences in OnePot PURE protein content (Fig. 1d, Supplementary Fig. S2). We observed high protein expression robustness across four biological replicates, especially for the 38% and 47% EF-Tu formulations, with coefficients of variation (CV) of 8% and 12%, respectively (Fig. 1e, f). In comparison, the CV for a technical replicate of PURExpress and HomeMade PURE were 5% and 12%, respectively. To avoid significant total protein concentration differences across replicates, we adjusted the concentration of the protein mixture to 1.6 mg/mL in the final reaction. This optimal concentration was chosen based on titrations of OnePot PURE (47% EF-Tu) replicate A (Supplementary Fig. S5).

We compared the protein composition of our OnePot PURE system to the commercially available PURExpress (NEB) and our HomeMade PURE system prepared based on the Shimizu protocol with minor adjustments [7]. From gels we determined that the overall composition of the PURExpress and HomeMade PURE systems were quite similar to one another as expected (Fig. 2a). Both PURExpress and HomeMade PURE had a higher relative percentage of EF-Tu and a lower total protein concentration (1 mg/mL for HomeMade PURE) than OnePot PURE. The relative intensities of individual proteins in the OnePot PURE deviated from the PURExpress and HomeMade PURE standards although the protein expression yield of the OnePot PURE system (47% EF-Tu) was similar to PURExpress, 1.6 times higher than our HomeMade PURE and 5 times higher than TraMOS (Fig. 2b).

One of the main factors limiting the use of the PURE system is its high cost. We performed a detailed cost analysis of different PURE systems: two systems prepared from individually purified protein components (PURExpress and HomeMade PURE), as well as two systems prepared from batch cultures and pooled purifications (OnePot and TraMOS) (Fig. 2c, Supplementary Table S1, S2, S3, S6). The commercial PURExpress is the most expensive at a cost of 1.36 USD/ $\mu$ L followed by TraMOS (0.96 USD/ $\mu$ L), HomeMade PURE (0.36 USD/ $\mu$ L), and OnePot PURE (0.09 USD/ $\mu$ L). For the HomeMade PURE and TraMOS preparations, cost originates primarily from protein components and ribosomes. The OnePot

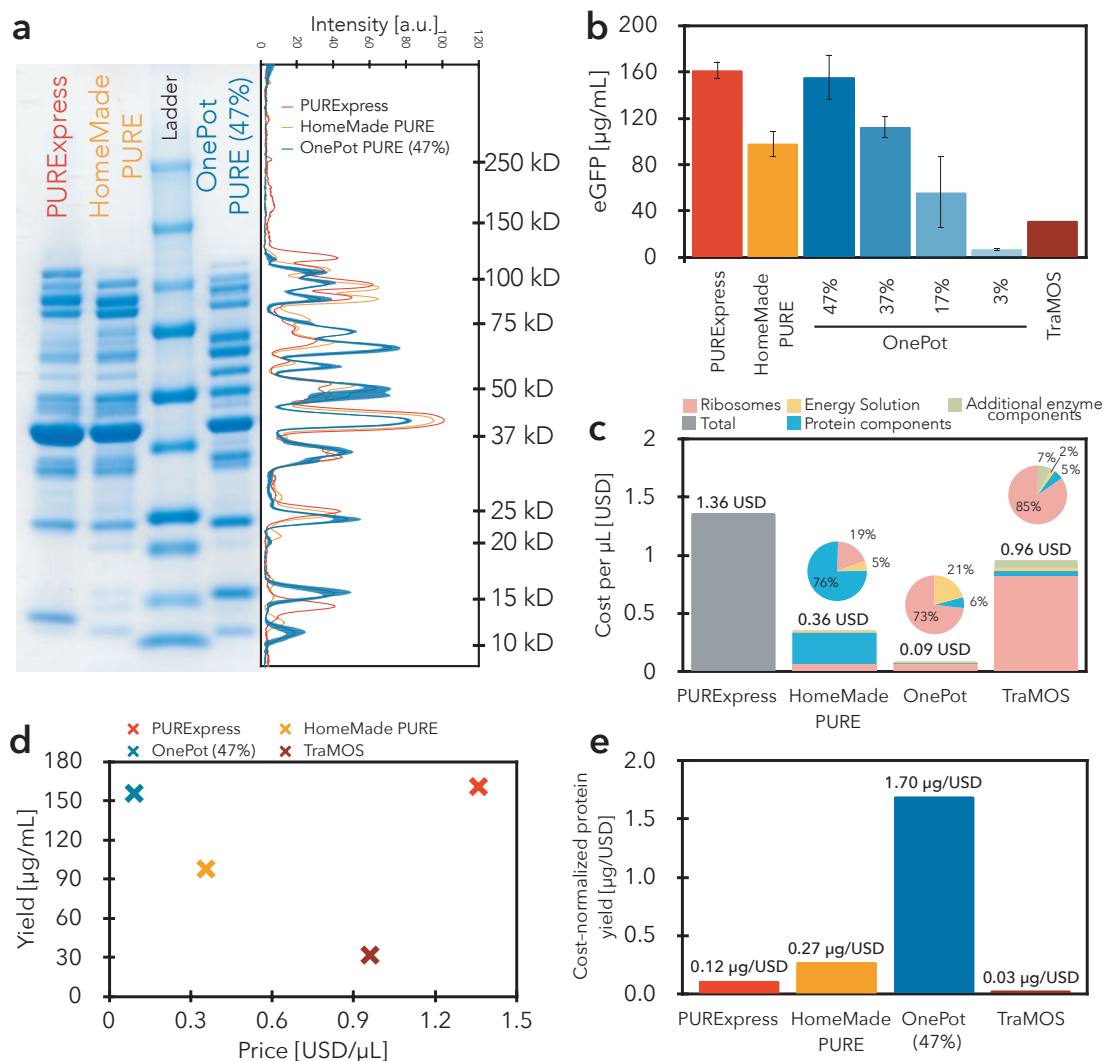

Figure 2: OnePot PURE comparison to existing PURE systems. **(a)** SDS-PAGE gel of PURExpress, HomeMadePURE, OnePot PURE (EF-Tu 47%, replicate A). In the right panel, intensities of different replicates are plotted with molecular weight standards (kDa). **(b)** Comparison of eGFP expression activity (after 3 h) of different PURE systems. The different systems were tested in the same conditions except for TraMOS where the reported value was used [17]. **(c)** Price comparison of the different PURE systems. Calculations are detailed in Supplementary Tables S1, S2, S3 S6. **(d)** Yield of the different PURE systems plotted against their price per  $\mu\text{L}$ . Mean values of the eGFP expression yield were plotted. **(e)** Cost-normalized yield of the different PURE systems. The mean value of the eGFP expression yield was used for the calculations.

approach reduces the cost of the protein components to almost negligible levels and relies on ribosome purification to further reduce cost. In-house ribosome purification does not only reduce the price by almost 16-fold as compared to when commercial ribosomes are used, but also allows for higher ribosome concentrations in the PURE system. The standard ribosome purification protocol used in this work is simple and robust. Moreover, in case ultracentrifugation is not accessible, His-tag purification of ribosomes could be a viable alternative [18, 20]. OnePot PURE substantially outperformed all other systems when directly comparing protein synthesis yield and cost per microliter (Fig. 2d) and achieved a cost normalized protein yield of  $1.70 \mu\text{g}/\text{USD}$  compared to  $0.27 \mu\text{g}/\text{USD}$  for HomeMade PURE,  $0.12 \mu\text{g}/\text{USD}$  for PURExpress, and  $0.03 \mu\text{g}/\text{USD}$  for TraMOS (Fig. 2e).

We demonstrated that it is possible to robustly produce a highly functional PURE system at low cost using a practical single batch culture and purification approach. The OnePot PURE system described here achieved a protein synthesis yield of  $156 \mu\text{g}/\text{mL}$  at a cost of  $0.09 \text{USD}/\mu\text{L}$ . At  $1.7 \mu\text{g}/\text{USD}$  the cost normalized protein synthesis yield is over a magnitude higher than the commercial PURE system and substantially higher than TraMOS. We also showed that it is possible to adjust and optimize the OnePot PURE system by varying the inoculation fraction of an individual strain. This simple, low-cost, and robust protocol for producing the PURE system should broaden access to the technology and enable new applications which hitherto were not feasible due to the high cost and complexity of producing the PURE system.

## MATERIALS AND METHODS

### *Escherichia coli* strains and plasmids

*E. coli* BL21(DE3) and M15 strains were used for protein expression. All plasmids encoding PURE proteins used in this work were originally obtained from Y. Shimizu (RIKEN Quantitative Biology Center, Japan). Genes coding for MK and PPIase were originally cloned in pET29b vectors with kanamycin resistance. To establish a OnePot system, we used CPEC assembly (Circular Polymerase Extension Cloning) [21] to clone a DNA fragment amplified from pET29b vectors containing MK and PPIase genes as well as the T7 promoter, RBS, and T7 terminator, into a pET21a vector containing ampicillin resistance. The primer

sequences used are listed in Supplementary Table S7. A list of the PURE proteins with their corresponding gene, vector and reference number are given in Supplementary Table S8. *E. coli* A19 (Coli Genetic Stock Center, CGSC#: 5997) was used for ribosome purification. The linear template DNA for *in vitro* eGFP synthesis was initially prepared by extension PCR from a pKT127 plasmid as described [2] and cloned into a pSBlue-1 plasmid. The DNA fragment used for PURE system characterization was amplified from this plasmid by PCR (Supplementary Table S7) and purified by DNA Clean and Concentrator-25 (Zymo Research). DNA was eluted in nuclease-free water instead of elution buffer. For all reactions, a linear template from a single purification was used.

### **Buffers used for protein and ribosome purification**

All buffers used in this work are listed in Supplementary Table S9. All buffers were filtered (Flow Bottle Top Filters, 0.45  $\mu\text{m}$  aPES membrane) and stored at 4°C. 2-mercaptoethanol was added immediately before use.

### **OnePot protein preparation**

Lysogeny broth (LB) used for OnePot protein component preparation was supplemented with 100  $\mu\text{g}/\text{mL}$  ampicillin and all cultures were grown at 37°C, 260 RPM. To allow for fast and easy inoculation, the different strains were stored as a glycerol stock in a single 96 well microplate. All overnight cultures were inoculated by a 96-well replicator (VP 408FS2AS, V & P Scientific), except for the EF-Tu strain, and grown in 0.3 mL of LB in a deep-well microplate (96 wells, void volume 1.5 mL). The strain expressing EF-Tu was grown in 3 mL of LB in a standard 14 mL culture tube. Overnight cultures (in total 3.6 mL) were used to inoculate 500 mL of LB media in a 1 L baffled flask. The exact composition of the inoculation cultures for different OnePot systems are given in Supplementary Table S4. Cells were grown 2 h before induction with 0.1 mM IPTG for 3 h, then harvested by centrifugation (4,000 RPM, 10 min, 4°C) and stored at  $-80^{\circ}\text{C}$  overnight. Cells were resuspended in 7.5 mL buffer A and lysed by sonication on ice (Vibra cell 75186 and probe tip diameter: 6 mm,  $4 \times 20\text{s}:20\text{s}$  pulse, 70% amplitude). Cell debris was removed by centrifugation (15,000 RPM, 20 min, 4°C). The supernatant was mixed with 2 mL of equilibrated resin, prepared

as described below, and incubated for 3 h, at 4°C. After the incubation, unbound lysate was allowed to flow through the column. The column was washed with 25 mL of a wash buffer (95% buffer A, 5% buffer B) and eluted with 5 mL of elution buffer (10% buffer A, 90% buffer B). Instead of dialysis, buffer exchange was done using a 15 mL Amicon Ultra filter unit with a 3 kDa molecular weight cutoff (Merck). All centrifugation steps were performed at 4,000 RPM and 4°C. The elution fraction was diluted with 25 mL of HT buffer and concentrated to 1 mL (2 × 60 min). The concentrated sample was then diluted with 10 mL of HT buffer, concentrated to 1.5 mL (60 min), and mixed with 1.5 mL of stock buffer B. The protein solution was then concentrated (14,000 RPM, 30 min, 4°C) using a 0.5 mL Amicon Ultra filter unit with a 3 kDa molecular weight cutoff (Merck) and stored at -80°C. Total protein concentration in the OnePot protein mixture was determined using a microplate Bradford protein assay with bovine gamma-globulin as a standard (Bio-Rad). Samples were diluted 1:25 and 5 µL of the diluted sample was mixed with 250 µL of Bradford reagent. Absorbance at 595 nm was measured using a SynergyMX platereader (BioTek). The OnePot protein mixture was then adjusted to a concentration of 12.25 mg/mL.

### **HomeMade PURE protein preparation**

Proteins were prepared by Ni-NTA gravity-flow chromatography. The LB medium used was supplemented with 100 µg/mL of ampicillin and/or 50 µg/mL of kanamycin (Supplementary Table S5), and all cultures were grown at 37°C, 250 RPM. Overnight cultures were grown in 3 mL of LB. Each strain was then individually inoculated in a flask with 2 L of LB. Cells were grown 2 h before induction with 0.1 mM of IPTG for 3 h, then harvested by centrifugation and stored at -80°C overnight. The cells were resuspended in 30 mL of buffer A and lysed by sonication on ice (Vibra cell 75186 and probe tip diameter: 6 mm, 8 × 20s:20s pulse, 70% amplitude). Cell debris was removed by centrifugation (25,000 RCF, 20 min, 4°C). The supernatant was mixed with 2-3 mL of equilibrated resin (described below), and incubated for 1-2 h, at 4°C. After the incubation, unbound lysate was allowed to flow through the column. The column was washed with 30 mL of a wash buffer (95% buffer A, 5% buffer B) and eluted with 15 mL of an elution buffer (10% buffer A, 90% buffer B). The elution fraction was dialysed against HT buffer (2×) and stock buffer and stored at -80°C. Protein concentrations were estimated by absorbance at 280 nm and calculated protein ex-

tion coefficients. When a higher protein concentration was required, the protein solution was concentrated using a 0.5 mL Amicon Ultra filter unit (Merck).

### **Ni-NTA resin preparation and regeneration**

2 mL IMAC Sepharose 6 FF (GE Healthcare) was pipetted into Econo-Pac chromatography columns (Bio-Rad), and charged with 15 mL of 100 mM nickel sulfate solution. The charged column was washed with 50 mL of DEMI water and equilibrated with 35 mL of buffer A. After protein purification, columns were regenerated with 10 mL of buffer containing 0.2 M EDTA and 0.5 M NaCl, and washed with 30 mL of 0.5 M NaCl, followed by 30 mL of demineralized water, and stored in 20% ethanol at 4°C.

### **OD600 measurement**

OD600 measurements of over-night cultures were measured on a 96-well plate with tenfold dilutions (20  $\mu$ L of over-night culture in 180  $\mu$ L of LB) using a SynergyMX platereader (BioTek). The background (OD600 of 200  $\mu$ L of LB) was subtracted from all samples.

### **Ribosome purification**

Ribosomes were prepared from *E. coli* A19 by hydrophobic interaction chromatography (HIC) and sucrose cushion buffer ultracentrifugation as described previously with slight modifications [22, 23]. *E. coli* A19 strain was grown overnight in 100 mL of LB media at 37°C. 2  $\times$  30 mL of the overnight cultures was used to inoculate 2  $\times$  2 L of LB. Cells were grown at 37°C, 250 RPM to exponential phase (3-4 h, OD600 = 0.6-0.8), harvested by centrifugation (4,000 RCF, 20 min, at 4°C), resuspended in 50 mL suspension buffer and stored at -80°C. The resuspended cells were lysed by sonication on ice (Vibra cell 75186 and probe tip diameter: 6 mm, 12  $\times$  20s:20s pulse, 70% amplitude). The cell debris was removed by centrifugation (20,000 RCF, 20 min, at 4°C). The recovered fraction was mixed with the same amount of high salt suspension buffer. The precipitate was removed by centrifugation (20,000 RCF, 20 min, at 4°C) and the supernatant was filtrated with a GD/X syringe filter membrane (0.45  $\mu$ m, PVDF, Whatman).

Ribosomes were purified using a 15 mL ( $3 \times 5$  mL HiTrap Butyl HP column (GE Healthcare) on Akta Purifier FPLC (GE Healthcare) at 4°C. After the column was equilibrated with 60 mL of buffer C, the prepared lysate solution was loaded onto the column and washed with 45 mL of wash buffer 1 (100% buffer C) followed by 75 mL of wash buffer 2 (80% buffer C, 20% buffer D). Ribosomes were eluted with 60 mL of ribosome elution buffer (50% buffer C, 50% buffer D) followed by 60 mL of final elution buffer (100% buffer D) at a flow rate of 4 mL per minute. All fractions containing ribosomes (absorbance peak at 280 nm during elution with ribosome elution buffer) were pooled together (around 55 mL). The column was recovered by washing with NaOH (1 M) and acetic acid (0.1 M), and stored in 20% ethanol.

14 mL of recovered fraction was overlaid onto 15 mL of cushion buffer in four polycarbonate tubes (void volume: 32 mL). The ribosomes were pelleted by ultracentrifugation (Beckman type SW 32 Ti rotor, 100,000 RCF, 16 h, 4°C). Each transparent ribosome pellet was washed two times with 0.5 mL ribosome buffer and resuspended with a magnetic stirrer in 100  $\mu$ M of ribosome buffer. To ensure that all the ribosomes are recovered every tube was washed with 100  $\mu$ M ribosome buffer. The recovered solution was concentrated using a 0.5 mL Amicon Ultra filter unit with a 3 kDa molecular weight cutoff (Merck) by centrifugation (14,000 RCF, 10 min, at 4°C). Ribosome concentrations were determined by measuring absorbance at 260 nm of a 1:100 dilution. An absorbance of 10 for the diluted solution corresponded to a 23  $\mu$ M concentration of undiluted ribosome solution. Final ribosome solution used for *in vitro* protein synthesis was prepared by diluting the sample to 10  $\mu$ M. The usual yield is above 0.75 mL of 10  $\mu$ M ribosome solution.

### **SDS-PAGE gels**

Proteins were separated by SDS-PAGE using 15-well 4-20% Mini-PROTEAN TGX Pre-cast Protein Gels (Bio-Rad). Gels were stained using Bio-Safe Coomassie stain (Bio-Rad), scanned using an EPSON Perfection V10 scanner and analyzed with ImageJ.

### **Energy solution preparation**

Energy solution was prepared as described previously with slight modifications [23]. 2.5 $\times$  energy solution contained 0.75 mM of each amino acid, 29.5 mM of magnesium acetate,

250 mM of potassium glutamate, 5 mM of ATP and GTP, 2.5 mM CTP, UTP, and DTT (Dithiothreitol), 130 U<sub>A260</sub>/mL of tRNA, 50 mM of creatine phosphate, 0.05 mM of folic acid, 5 mM of spermidine, and 125 mM of HEPES.

### ***In vitro* protein expression**

HomeMade or OnePot PURE reactions (5  $\mu$ L) were established by mixing 2  $\mu$ L of 2.5  $\times$  energy solution, 1.45  $\mu$ L linear eGFP DNA template (final concentration: 5 nM), 0.9  $\mu$ L of 10  $\mu$ M ribosomes (final concentration: 1.8  $\mu$ M) and 0.65  $\mu$ L of PURE proteins (HomeMade or OnePot solution). PURExpress reactions (5  $\mu$ L) were established by mixing 2  $\mu$ L of solution A, 1.5  $\mu$ L eGFP DNA (final concentration: 5 nM) and 1.5  $\mu$ L of solution B. Reactions were incubated at 37°C at constant shaking for 3 h, and measured (excitation: 488 nm, emission: 507 nm) on a SynergyMX plater reader (BioTek). Absolute eGFP concentrations were determined from a standard curve (Supplementary Fig. S7).

### **Cost calculations**

To estimate the cost of PURE systems, we analyzed in detail the costs of the different subsets: protein components, ribosomes, and energy solution. The calculation for protein subset costs varies with the type of the system. For the TraMOS system, the reported cost of 0.052 USD/ $\mu$ L was used [17]. For our OnePot system, the cost was estimated based on the calculations given in Supplementary Table S1, with the assumptions that some of the materials can be reused and that four purifications can be done simultaneously in one working day. In the case of the HomeMade PURE system, our estimate was based on the price charged by the EPFL protein expression core facility: 300 USD per 2 L expression culture, which corresponds to our calculation for OnePot PURE of 83 USD per 0.5 L culture (332 USD for 2 L, Supplementary Table S1). Although the total price of this PURE system is high, the total amount of proteins purified is higher as well which can generate at least 40 mL of PURE HomeMade system (based on the volume of the protein limiting the preparation, in our case EF-Tu). Therefore, the price per  $\mu$ L of HomeMade protein components is 0.27 USD.

Two different possibilities were taken into account in the case of the ribosome subset. In

the first system, commercial ribosomes (Supplementary Table S6) were used for the PURE reactions (TraMOS). In the second system, purified ribosomes were used (HomeMade and OnePot PURE). The cost calculations for purified ribosomes are given in Supplementary Table S2, with the assumptions that some of the materials can be reused and that hands-on time for one purification is a single working day.

The cost calculation for the OnePot energy solution is described in Supplementary Table S3, with the assumption that half a day is necessary for the preparation of 20 mL of energy solution. For the TraMOS energy solution and the additional protein components, the costs were recalculated based on the component's price that would apply for the preparation of the given solutions (Supplementary Table S6). For some of the additional protein components, we were not able to determine the exact protein which was purchased and its amount used, mostly due to a difference in the type of units reported in the paper as compared to the units specified by the supplier. However, we arrived at a very similar cost estimate as given in the original calculation. Furthermore, we assumed that the work required for the solution preparation is taken into account in the purification cost calculation, so we did not consider it.

In the case of PURExpress, the total cost was based on the commercial price. The values used in the cost calculation were derived from experience with the actual experiments while preparing the different subsets. All costs for the different components were based on the prices given in our internal EPFL system when performing the calculation; no delivery costs were taken into account.

## ACKNOWLEDGEMENTS

We thank Yoshihiro Shimizu (RIKEN) for kindly supplying plasmids for the PURE system, members of the EPFL Protein Crystallography and Protein Expression Core Facilities, especially Jean Philippe Gaudry for providing us with purified PURE protein components and help with ribosome purification and Nadanai Laohakunakorn for helpful discussions. We also thank Corinna Tuckey and John DeMartino from NEB for providing us with custom PURExpress kits. This work was supported by the École Polytechnique Fédérale de Lausanne.

## AUTHOR CONTRIBUTIONS

B.L. performed experiments. B.L. and S.J.M. designed experiments, analyzed data, and wrote the manuscript.

## DECLARATION OF INTERESTS

The authors declare no competing interests.

## SUPPLEMENTAL FIGURES AND TABLES

Figure S1: Schematics depicting all steps of the OnePot PURE production. **(a)** Protein purification, **(b)** ribosome purification, and **(c)** energy solution preparation steps. The description of the different steps as well as the day on which they are performed are indicated below the schematics. **(d)** Composition of the OnePot PURE reaction. Two numbers are given for each subset, the volume required for a 5  $\mu$ L reaction and the component concentration in the reaction.

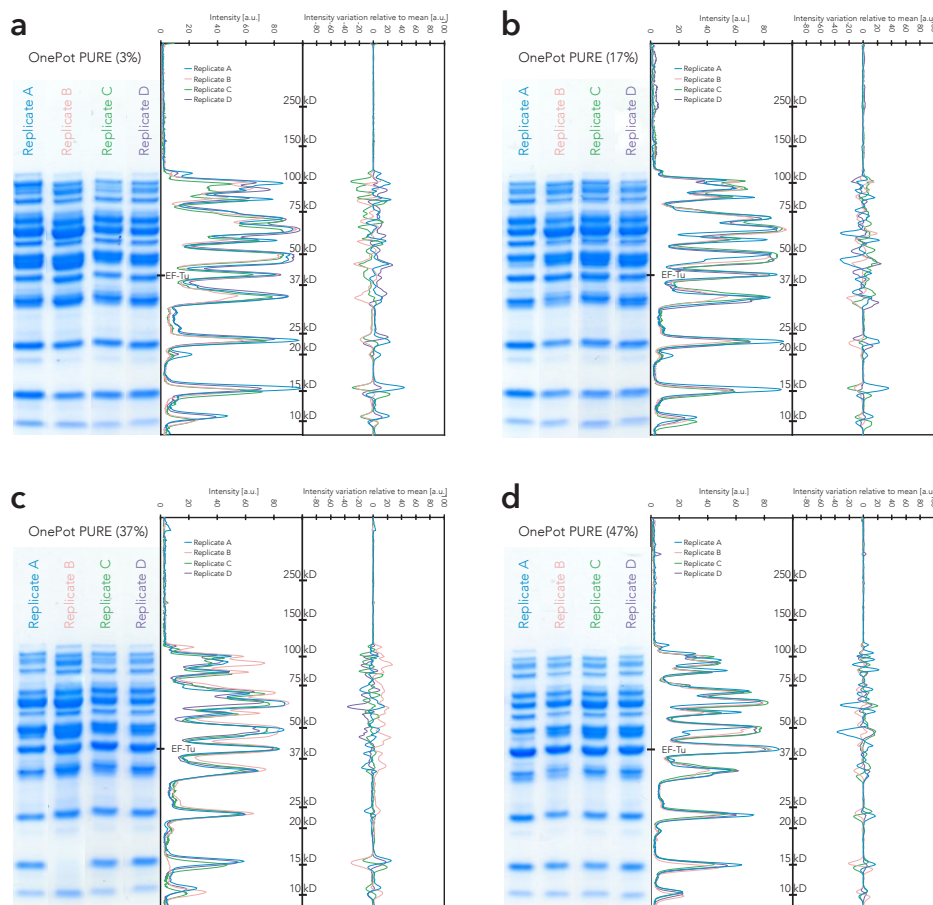

Figure S2: Coomassie blue stained SDS-PAGE gels of the four OnePot PURE formulations. (a) 3% EF-Tu, (b) 17% EF-Tu, (c) 37% EF-Tu, and (d) 47% EF-Tu. In the panels to the left of the gels, intensities of the different replicates are plotted with molecular weight standards (kDa). On the right the intensity variations relative to the inter-replicate mean is shown.

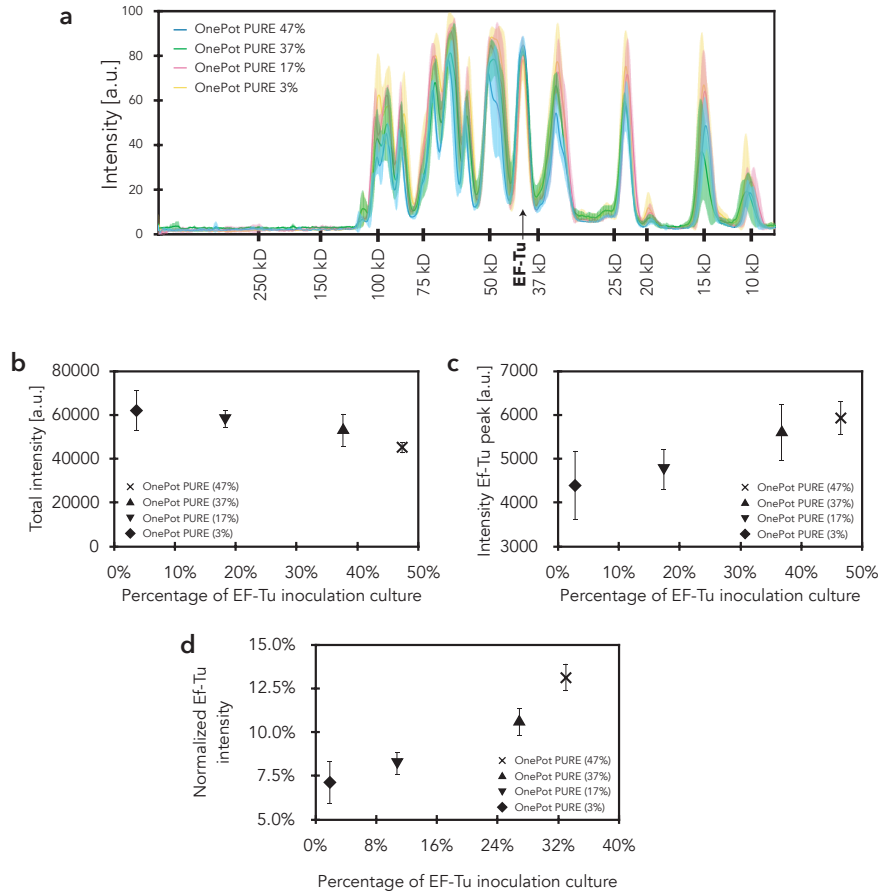

Figure S3: EF-Tu analysis. **(a)** Mean intensities of the different OnePot systems are plotted against molecular weight standards (kDa); the shaded regions represent the s.d. of the four biological replicates. **(b)** Total intensity of all protein bands as a function of EF-Tu clone inoculation percentage. **(c)** The integrated intensity of the EF-Tu peak from SDS-PAGE gel analysis as a function of EF-Tu clone inoculation percentage. **(d)** The normalised EF-Tu intensity (integrated EF-Tu peak intensity / total protein intensity) as a function of EF-Tu clone inoculation percentage. **(b) - (d)** Each data point represents four biological replicates (mean  $\pm$  s.d.)

Figure S4: OD600 measurement of overnight cultures used for inoculation of the mixed culture.

Figure S5: Protein concentration calibrations and adjustments. **(a)** Bradford assay standard calibration curve for protein concentration. The standard curve was produced by measuring the absorbance at 595 nm of prediluted bovine  $\gamma$ -globulin standards. Data are shown as mean  $\pm$  s.d. ( $n = 3$ ). Linear fit errors were not propagated as they were negligible compared to experimental errors. **(b)** eGFP expression as a function of protein concentrations in the protein subset of OnePot PURE (47%) replicate A ( $7.7 \times$  concentration in the final reaction). Each point represents at least two replicates; data are shown as mean  $\pm$  s.d. **(c)** The concentrations of all OnePot protein subsets and their replicates after purification. Each bar represents two independent measurements in technical duplicate. Data are shown as mean  $\pm$  s.d. The dotted line represents concentration (12.25 mg/mL, which is equal to 1.6 mg/mL in the final PURE reaction) to which all reactions were adjusted to.

Figure S6: Standard calibration curve for EF-Tu protein concentration. **(a)** Coomassie blue stained SDS-PAGE gels of different concentrations of EF-Tu. **(b)** The standard curve was produced by measuring the integrated intensity of the EF-Tu peak at different EF-Tu concentrations. The reference EF-Tu concentration was determined by absorbance measurement at 280 nm.

Figure S7: Standard calibration curve for eGFP. The standard curve was produced by measuring the fluorescence over 60 min for different eGFP (TP790050, AMS Biotechnology) concentrations in PBS on a plate reader with the same settings as for *in vitro* expression. Excitation and emission wavelengths were 488 nm and 507 nm, respectively. Experiments were performed in triplicates. Fluorescence measurements for the first 20 min were not considered. Data are shown as mean  $\pm$  s.d. ( $n = 3$ ). Linear fit errors were not propagated as they were negligible compared to experimental errors.

TABLE S8: PURE protein list

Number	Protein	Protein name	Gene	Organism	Vector used for Home Made PURE	Vector used for OnePot PURE	Expression Strain
1	<b>AlaRS</b>	Alanyl-tRNA synthetase	alaS	E. coli	pQE30	pQE31	M15
2	<b>ArgRS</b>	Arginyl-tRNA synthetase	argS	E. coli	pET16b	pET16b	BL21(DE3)
3	<b>AsnRS</b>	Asparaginyl-tRNA synthetase	asnS	E. coli	pQE30	pQE31	M15
4	<b>AspRS</b>	Aspartate-tRNA synthetase	aspS	E. coli	pET21a	pET21a	BL21(DE3)
5	<b>CysRS</b>	Cysteiny-tRNA synthetase	cysS	E. coli	pET21a	pET21a	BL21(DE3)
6	<b>GlnRS</b>	Glutaminy-tRNA synthetase	glnS	E. coli	pET21a	pET21a	BL21(DE3)
7	<b>GluRS</b>	Glutamyl-tRNA synthetase	gltX	E. coli	pET21a	pET21a	BL21(DE3)
8	<b>GlyRS</b>	Glycyl-tRNA synthetase	glyO & glyS	E. coli	pET21a	pET21a	BL21(DE3)
9	<b>HisRS</b>	Histidyl-tRNA synthetase	hisS	E. coli	pET21a	pET21a	BL21(DE3)
10	<b>IleRS</b>	Isoleucyl-tRNA synthetase	ileS	E. coli	pET21a	pET21a	BL21(DE3)
11	<b>LeuRS</b>	Leucyl-tRNA synthetase	leuS	E. coli	pET21a	pET21a	BL21(DE3)
12	<b>LysRS</b>	Lysyl-tRNA synthetase	lysS	E. coli	pET21a	pET21a	BL21(DE3)
13	<b>MetRS</b>	Methionine-tRNA ligase	metG	E. coli	pET21a	pET21a	BL21(DE3)
14	<b>PheRS</b>	Phenylalanyl-tRNA synthetase	pheT & pheS	E. coli	pQE30	pQE31	M15
15	<b>ProRS</b>	Prolyl-tRNA synthetase	proS	E. coli	pET21a	pET21a	BL21(DE3)
16	<b>SerRS</b>	Seryl-tRNA synthetase	serS	E. coli	pET21a	pET21a	BL21(DE3)
17	<b>ThrRS</b>	Threonyl-tRNA synthetase	thrS	E. coli	pQE30	pQE31	M15
18	<b>TrpRS</b>	Tryptophanyl-tRNA synthetase	trpS	E. coli	pET21a	pET21a	BL21(DE3)
19	<b>TyrRS</b>	Tyrosyl-tRNA synthetase	tyrS	E. coli	pET21a	pET21a	BL21(DE3)
20	<b>ValRS</b>	Valyl-tRNA synthetase	valS	E. coli	pET21a	pET21a	BL21(DE3)
21	<b>IF1</b>	Initiation factor 1	infA	E. coli	pQE30	pQE31	M15
22	<b>IF2</b>	Initiation factor 2	infB	E. coli	pQE30	pQE31	M15
23	<b>IF3</b>	Initiation factor 3	infC	E. coli	pQE30	pQE31	M15
24	<b>EF-G</b>	Elongation factor G	fusA	E. coli	pQE60	pQE61	M15
25	<b>EF-Tu</b>	Elongation factor Tu	tufB	E. coli	pQE60	pQE61	M15
26	<b>EF-Ts</b>	Elongation factor Ts	tsf	E. coli	pQE60	pQE61	M15
27	<b>RF1</b>	Release factor 1	prfA	E. coli	pQE30	pQE31	M15
28	<b>RF2</b>	Release factor 2	prfB	E. coli	pET15b	pET15b	BL21(DE3)
29	<b>RF3</b>	Release factor 4	prfC	E. coli	pQE30	pQE31	M15
30	<b>RRF</b>	Ribosome recycling factor	frr	E. coli	pQE60	pQE61	M15
31	<b>MTF</b>	Methionyl-tRNA formyltransferase	fmt	E. coli	pET21a	pET21a	BL21(DE3)
32	<b>CK</b>	Creatine kinase	CKM	Chicken	pQE30	pQE31	M15
33	<b>MK</b>	Adenylate kinase (Myokinase)	AK1	Chicken	pET29b	pET21a	BL21(DE3)
34	<b>NDK</b>	Nucleotide diphosphate kinase	ndk	E. coli	pQE30	pQE31	M15
35	<b>PPIase</b>	Inorganic pyrophosphatase	IPP1	Saccharomyces cerevisiae	pET29b	pET21a	BL21(DE3)
36	<b>T7 RNAP</b>	T7 RNA polymerase	1	Enterobacteria phage T7	pQE30	pQE31	M15

TABLE S9: Buffers and energy solution

Bufferes for protein purification

Compound	Catalog number	Company	Buffer A	Buffer B	Buffer HT	Stock buffer	Stock buffer B	Note
			mM	mM	mM	mM	mM	
HEPES	H0887-100ML	Sigma-Aldrich	50	50	50	50	50	pH = 7.6, KOH
Ammonium chloride	09718-250G	Sigma-Aldrich	1000					
Magnesium chloride	63020-1L	Honeywell Fluka	10	10	10	10	10	
Potassium chloride	P5405-1KG	Sigma-Aldrich		100	100	100	100	
Imidasol	I2399	Sigma-Aldrich		500				pH = 7.6, KOH
Glycerol	G7757-1L	Sigma-Aldrich				30%	60%	
$\beta$ -mercaptoethanol	M6250-100ML	Sigma-Aldrich	7	7	7	7	7	

Bufferes for ribosomes purification

Compound	Catalog number	Company	Suspension buffer	Suspension buffer high salt	Buffer C	Buffer D	Cusion buffer	Ribosome buffer	Note
			mM	mM	mM	mM	mM	mM	
HEPES	H0887-100ML	Sigma-Aldrich	10	10	20	20	20	20	pH = 7.6, KOH
Magnesium acetate	M0631	Sigma-Aldrich	10	10	10	10	10	6	
Potassium chloride	P5405-1KG	Sigma-Aldrich	50	50				30	
Ammonium chloride	09718-250G	Sigma-Aldrich					30		
Ammonium sulfate	A4418	Sigma-Aldrich		3000	1500				pH = 7.6, KOH
Sucrose	84097	Sigma-Aldrich					30%		
$\beta$ -mercaptoethanol	M6250-100ML	Sigma-Aldrich	7	7	7	7	7	7	

Energy Solution

Compound	Catalog number	Company	Concentration in reaction	Concentration in subset (2.5x)	Units
Amino acids	LAA21-1KT	Sigma-Aldrich	0.3	0.75	mM
Magnesium acetate	M0631	Sigma-Aldrich	11.8	29.5	mM
Potassium glutamate	49601	Sigma-Aldrich	100	250	mM
DTT	sc-29089B	SantaCruz Biotech	1	2.5	mM
ATP	R0481	ThermoFisher	2	5	mM
GTP	R0481	ThermoFisher	2	5	mM
CTP	R0481	ThermoFisher	1	2.5	mM
UTP	R0481	ThermoFisher	1	2.5	mM
tRNA	10109541001	Roche	52	130	U <sub>A260</sub> /mL
Creatine phosphate	27920	Sigma-Aldrich	20	50	mM
Folnic acid	F7876	Sigma-Aldrich	0.02	0.1	mM
Spermidine	S2626	Sigma-Aldrich	2	5	mM
HEPES	H0887-100ML	Sigma-Aldrich	50	125	mM
